WARNING – EXPORT NOTICE: Recipient agrees to not knowingly export or re-export, directly or indirectly, any product or technical data (as defined by the U.S., EU, and other Export Administration Regulations) including software, or any controlled product restricted by other applicable national regulations, received from Disclosing party under this Agreement, or any direct product of such technology, to any destination to which such export or re-export is restricted or prohibited by U.S. or other applicable laws, without obtaining prior authorization from U.S. Department of Commerce and other competent Government authorities to the extent required by those laws.

According to our best knowledge of the state and end-use of this product or technology, and in compliance with the export control regulations of dual-use goods in force in the origin and exporting countries, this technology is classified as follows:

- US ECCN: EAR99
- EU ECCN: EAR99

And may require export or re-export license for shipping it in compliance with the applicable regulations of certain countries.

8.1	Block Diagram	630
8.2	Functional Description	632
8.2.1	SRAM	632
8.2.2	ROM	632
8.2.3	Flash Memory	634
8.2.4	EEPROM	645
8.2.5	Bus Matrix Memory Accesses	650

8.3	Register Map	650
8.4	Internal Memory Register Descriptions (Internal Memory Control Offset)	652
8.5	EEPROM Register Descriptions (EEPROM Offset)	678
8.6	Memory Register Descriptions (System Control Offset)	695
9	Micro Direct Memory Access (μDMA)	705
9.1	Block Diagram	706
9.2	Functional Description	706
9.2.1	Channel Assignments	707
9.2.2	Priority	708
9.2.3	Arbitration Size	709
9.2.4	Request Types	709
9.2.5	Channel Configuration	710
9.2.6	Transfer Modes	712
9.2.7	Transfer Size and Increment	720
9.2.8	Peripheral Interface	720
9.2.9	Software Request	721
9.2.10	Interrupts and Errors	721
9.3	Initialization and Configuration	721
9.3.1	Module Initialization	721
9.3.2	Configuring a Memory-to-Memory Transfer	722
9.3.3	Configuring a Peripheral for Simple Transmit	723
9.3.4	Configuring a Peripheral for Ping-Pong Receive	725
9.3.5	Configuring Channel Assignments	728
9.4	Register Map	728
9.5	μ DMA Channel Control Structure	729
9.6	μ DMA Register Descriptions	736
10	General-Purpose Input/Outputs (GPIOs)	769
10.1	Signal Description	770
10.2	Pad Capabilities	775
10.3	Functional Description	775
10.3.1	Data Control	777
10.3.2	Interrupt Control	779
10.3.3	Mode Control	780
10.3.4	Commit Control	781
10.3.5	Pad Control	781
10.3.6	Identification	782
10.4	Initialization and Configuration	782
10.5	Register Map	784
10.6	Register Descriptions	787
11	External Peripheral Interface (EPI)	844
11.1	EPI Block Diagram	845
11.2	Signal Description	846
11.3	Functional Description	847
11.3.1	Master Access to EPI	848
11.3.2	Non-Blocking Reads	848
11.3.3	DMA Operation	849
11.4	Initialization and Configuration	850
11.4.1	EPI Interface Options	851

11.4.2	SDRAM Mode	851
11.4.3	Host Bus Mode	855
11.4.4	General-Purpose Mode	876
11.5	Register Map	883
11.6	Register Descriptions	885
12	Cyclical Redundancy Check (CRC)	975
12.1	Functional Description	975
12.1.1	CRC Support	975
12.2	Initialization and Configuration	977
12.2.1	CRC Initialization and Configuration	977
12.3	Register Map	978
12.4	CRC Module Register Descriptions	978
13	Advance Encryption Standard Accelerator (AES)	984
13.1	AES Overview	984
13.2	AES Functional Description	984
13.2.1	AES Block Diagram	985
13.2.2	AES Algorithm	988
13.2.3	AES Operating Modes	989
13.2.4	AES Software Reset	997
13.2.5	Power Management	997
13.2.6	Hardware Requests	997
13.3	AES Performance Information	998
13.4	AES Module Programming Guide	1000
13.4.1	AES Low - Level Programming Models	1000
13.5	Register Map	1005
13.6	AES Register Descriptions	1007
13.7	AES µDMA Interrupt Register Descriptions (CCM Offset)	1029
14	Data Encryption Standard Accelerator (DES)	1036
14.1	DES Functional Description	1036
14.2	DES Block Diagram	1037
14.2.1	µDMA Control	1037
14.2.2	Interrupt Control	1038
14.2.3	Register Interface	1038
14.2.4	DES Engine	1038
14.3	Software Reset	1039
14.4	DES Supported Modes of Operation	1039
14.4.1	ECB Feedback Mode	1039
14.5	DES Module Programming Guide -Low Level Programming Models	1041
14.5.1	Surrounding Modules Global Initialization	1041
14.5.2	Operational Modes Configuration	1042
14.5.3	DES Events Servicing	1044
14.6	Register Map	1045
14.7	DES Register Description	1046
14.8	DES µDMA Interrupt Register Descriptions (CCM Offset)	1060
15	SHA/MD5 Accelerator	1065
15.1	SHA/MD5 Functional Description	1065
15.1.1	SHA/MD5 Block Diagram	1065

15.1.2 Power Management	1067
15.1.3 Reset Management	1067
15.1.4 μ DMA and Interrupt Requests	1067
15.1.5 Operation Description	1068
15.1.6 SHA/MD5 Performance Information	1074
15.1.7 SHA/MD5 Programming Guide	1075
15.2 SHA/MD5 Register Map	1079
15.3 SHA/MD5 Register Descriptions	1081
15.4 SHA/MD5 μ DMA Control Register Descriptions (Encryption Control Offset)	1095
16 General-Purpose Timers	1100
16.1 Block Diagram	1101
16.2 Signal Description	1102
16.3 Functional Description	1103
16.3.1 GPTM Reset Conditions	1104
16.3.2 Timer Clock Source	1104
16.3.3 Timer Modes	1105
16.3.4 Wait-for-Trigger Mode	1114
16.3.5 Synchronizing GP Timer Blocks	1115
16.3.6 DMA Operation	1116
16.3.7 ADC Operation	1116
16.3.8 Accessing Concatenated 16/32-Bit GPTM Register Values	1116
16.4 Initialization and Configuration	1117
16.4.1 One-Shot/Periodic Timer Mode	1117
16.4.2 Real-Time Clock (RTC) Mode	1118
16.4.3 Input Edge-Count Mode	1118
16.4.4 Input Edge Time Mode	1119
16.4.5 PWM Mode	1119
16.5 Register Map	1120
16.6 Register Descriptions	1121
17 Watchdog Timers	1173
17.1 Block Diagram	1174
17.2 Functional Description	1174
17.2.1 Register Access Timing	1175
17.3 Initialization and Configuration	1175
17.4 Register Map	1175
17.5 Register Descriptions	1176
18 Analog-to-Digital Converter (ADC)	1198
18.1 Block Diagram	1199
18.2 Signal Description	1200
18.3 Functional Description	1201
18.3.1 Sample Sequencers	1202
18.3.2 Module Control	1202
18.3.3 Hardware Sample Averaging Circuit	1208
18.3.4 Analog-to-Digital Converter	1208
18.3.5 Differential Sampling	1211
18.3.6 Internal Temperature Sensor	1213
18.3.7 Digital Comparator Unit	1214
18.4 Initialization and Configuration	1218

18.4.1	Module Initialization	1218
18.4.2	Sample Sequencer Configuration	1219
18.5	Register Map	1219
18.6	Register Descriptions	1222
19	Universal Asynchronous Receivers/Transmitters (UARTs)	1307
19.1	Block Diagram	1308
19.2	Signal Description	1308
19.3	Functional Description	1310
19.3.1	Transmit/Receive Logic	1311
19.3.2	Baud-Rate Generation	1311
19.3.3	Data Transmission	1312
19.3.4	Serial IR (SIR)	1312
19.3.5	ISO 7816 Support	1314
19.3.6	Modem Handshake Support	1314
19.3.7	9-Bit UART Mode	1315
19.3.8	FIFO Operation	1316
19.3.9	Interrupts	1316
19.3.10	Loopback Operation	1317
19.3.11	DMA Operation	1317
19.4	Initialization and Configuration	1318
19.5	Register Map	1319
19.6	Register Descriptions	1321
20	Quad Synchronous Serial Interface (QSSI)	1373
20.1	Block Diagram	1373
20.2	Signal Description	1374
20.3	Functional Description	1376
20.3.1	Bit Rate Generation	1376
20.3.2	FIFO Operation	1376
20.3.3	Advanced, Bi- and Quad- SSI Function	1377
20.3.4	SSInFSS Function	1378
20.3.5	High Speed Clock Operation	1379
20.3.6	Interrupts	1379
20.3.7	Frame Formats	1380
20.3.8	DMA Operation	1387

Revision History

The revision history table notes changes made between the indicated revisions of the TM4C129XKCZAD data sheet.

Table 1. Revision History

Date	Revision	Description
December 2013	15638.2711	<ul style="list-style-type: none"> ■ Changed NDA (Non-Disclosure Agreement) footer to indicate NDA only applies to USB content. ■ In System Control chapter: <ul style="list-style-type: none"> – Added sections "Optional Clock Output Signal (DIVSCLK)" and "Hardware System Service Request". – Removed some registers and bits: <ul style="list-style-type: none"> • LDORDRIS bit from Raw Interrupt Status (RIS) register, LDORDIM bit from Interrupt Mask Control (IMC) register, and LDORDMIS bit from Masked Interrupt Status and Clear (MISC) register • Deep Sleep Mode Memory Timing Register 0 for Main Flash and EEPROM (DSMEMTIM0) register • LDO Power Calibration (LDOPCAL) register • LDO Sleep Power Control (LDOSPCTL) register • LMINERR bit from Sleep/Deep-Sleep Power Mode Status (SDPMST) register – Added LDOSME, TSPDE, PIOSCPDE, SRAMSM, SRAMLPM, FLASHLPM, and LDOSEQ bits in SYSPROP register. ■ In Internal Memory chapter: <ul style="list-style-type: none"> – Added subsections to "Flash Memory" section about Execute-Only Protection, Read-Only Protection and Permanently Disabling Debug. – Removed INVPL bit from EEPROM Done Status (EEDONE) register. – Updated table "MEMTIM0 Register Configuration vs. Frequency" with lower wait states, and improved performance values. – Added EEPROM initialization code to "EEPROM Initialization and Configuration" section. ■ In the ADC chapter: <ul style="list-style-type: none"> – Added section "Sample and Hold Window Control" and clarified section "Sample Phase Control". – Clarified description of ADC Sample Phase Control (ADCSPC) register. ■ Updated Electrical Characteristics chapter based on characterization information received.
October 2013	15440.2698	Initial release of NDA data sheet.

About This Document

This data sheet provides reference information for the TM4C129XKCZAD microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M4F core.

Audience

This manual is intended for system software developers, hardware designers, and application developers.

About This Manual

This document is organized into sections that correspond to each major feature.

Documentation Conventions

This document uses the conventions shown in Table 2 on page 55.

Table 2. Documentation Conventions

Notation	Meaning
General Register Notation	
REGISTER	APB registers are indicated in uppercase bold. For example, PBORCTL is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, SRCRn represents any (or all) of the three Software Reset Control registers: SRCR0 , SRCR1 , and SRCR2 .
bit	A single bit in a register.
bit field	Two or more consecutive and related bits.
offset 0xnnnn	A hexadecimal increment to a register's address, relative to that module's base address as specified in Table 2-4 on page 112.
Register N	Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.
reserved	Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
yy:xx	The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.
Register Bit/Field Types	This value in the register bit diagram indicates whether software running on the controller can change the value of the bit field.
RC	Software can read this field. The bit or field is cleared by hardware after reading the bit/field.
RO	Software can read this field. Always write the chip reset value.
RW	Software can read or write this field.
RWC	Software can read or write this field. Writing to it with any value clears the register.
RW1C	Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read.
RW1S	Software can read or write a 1 to this field. A write of a 0 to a RW1S bit does not affect the bit value in the register.
W1C	Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data. This register is typically used to clear the corresponding bit in an interrupt register.
WO	Only a write by software is valid; a read of the register returns no meaningful data.
Register Bit/Field Reset Value	This value in the register bit diagram shows the bit/field value after any reset, unless noted.
0	Bit cleared to 0 on chip reset.
1	Bit set to 1 on chip reset.
-	Nondeterministic.
Pin/Signal Notation	
[]	Pin alternate function; a pin defaults to the signal without the brackets.
pin	Refers to the physical connection on the package.
signal	Refers to the electrical signal encoding of a pin.

Table 2. Documentation Conventions (continued)

Notation	Meaning
assert a signal	Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see SIGNAL and <u>SIGNAL</u> below).
deassert a signal	Change the value of the signal from the logically True state to the logically False state.
SIGNAL	Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert SIGNAL is to drive it Low; to deassert SIGNAL is to drive it High.
SIGNAL	Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert SIGNAL is to drive it High; to deassert SIGNAL is to drive it Low.
Numbers	
X	An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.
0x	Hexadecimal numbers have a prefix of 0x. For example, 0x0FF is the hexadecimal number FF. All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix.

1 Architectural Overview

Texas Instrument's Tiva™ C Series microcontrollers provide designers a high-performance ARM® Cortex™-M-based architecture with a broad set of integration capabilities and a strong ecosystem of software and development tools. Targeting performance and flexibility, the Tiva™ C Series architecture offers a 120 MHz Cortex-M with FPU, a variety of integrated memories and multiple programmable GPIO. Tiva™ C Series devices offer consumers compelling cost-effective solutions by integrating application-specific peripherals and providing a comprehensive library of software tools which minimize board costs and design-cycle time. Offering quicker time-to-market and cost savings, the Tiva™ C Series microcontrollers are the leading choice in high-performance 32-bit applications.

This chapter contains an overview of the Tiva™ C Series microcontrollers as well as details on the TM4C129XKCZAD microcontroller:

- “Tiva™ C Series Overview” on page 57
- “TM4C129XKCZAD Microcontroller Overview” on page 58
- “TM4C129XKCZAD Microcontroller Features” on page 61
- “TM4C129XKCZAD Microcontroller Hardware Details” on page 87
- “Kits” on page 87
- “Support Information” on page 88

1.1 Tiva™ C Series Overview

The Tiva™ C Series ARM Cortex-M4 microcontrollers provide top performance and advanced integration. The product family is positioned for cost-effective applications requiring significant control processing and connectivity capabilities such as:

- Industrial communication equipment
- Network appliances, gateways & adapters
- Residential & commercial site monitoring & control
- Remote connectivity & monitoring
- Security/access systems
- HMI control panels
- Factory automation control
- Test and measurement equipment
- Fire & security systems
- Motion control & power inversion
- Medical instrumentation
- Gaming equipment
- Electronic point-of-sale (POS) displays
- Smart Energy/Smart Grid solutions
- Intelligent lighting control
- Vehicle tracking

Tiva™ C Series microcontrollers integrate a large variety of rich communication features to enable a new class of highly connected designs with the ability to allow critical, real-time control between performance and power. The microcontrollers feature integrated communication peripherals along with other high-performance analog and digital functions to offer a strong foundation for many different target uses, spanning from human machine interface to networked system management controllers.

In addition, Tiva™ C Series microcontrollers offer the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure, and a large user community. Additionally, these microcontrollers use ARM's Thumb®-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, the TM4C129XKCZAD microcontroller is code-compatible to all members of the extensive Tiva™ C Series, providing flexibility to fit precise needs.

Texas Instruments offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network.

1.2 TM4C129XKCZAD Microcontroller Overview

The TM4C129XKCZAD microcontroller combines complex integration and high performance with the features shown in Table 1-1.

Table 1-1. TM4C129XKCZAD Microcontroller Features

Feature	Description
Performance	
Core	ARM Cortex-M4F processor core
Performance	120-MHz operation; 150 DMIPS performance
Flash	512 KB Flash memory
System SRAM	256 KB single-cycle System SRAM
EEPROM	6KB of EEPROM
Internal ROM	Internal ROM loaded with TivaWare™ for C Series software
External Peripheral Interface (EPI)	8-/16-/32-bit dedicated interface for peripherals and memory
Security	
Cyclical Redundancy Check (CRC) Hardware	16-/32-bit Hash function that supports four CRC forms
Advanced Encryption Standard (AES)	Hardware accelerated data encryption and decryption based on 128-, 192-, and 256-bit keys
Data Encryption Standard (DES)	Block cipher implementation with 168-bit effective key length
Hardware Accelerated Hash (SHA/MD5)	Advanced hash engine that supports SHA-1, SHA-2 or MD5 Hash computation
Tamper	Support for four tamper inputs and configurable tamper event response
Communication Interfaces	
Universal Asynchronous Receivers/Transmitter (UART)	Eight UARTs
Quad Synchronous Serial Interface (QSSI)	Four SSI modules with Bi-, Quad- and advanced SSI support
Inter-Integrated Circuit (I^2C)	Ten I^2C modules with four transmission speeds including high-speed mode
Controller Area Network (CAN)	Two CAN 2.0 A/B controllers
Ethernet MAC	10/100 Ethernet MAC with Media Independent Interface (MII) and Reduced MII (RMII)
Ethernet PHY	PHY with IEEE 1588 PTP hardware support
Universal Serial Bus (USB)	USB 2.0 OTG/Host/Device with ULPI interface option and Link Power Management (LPM) support
System Integration	
Micro Direct Memory Access (μ DMA)	ARM® PrimeCell® 32-channel configurable μ DMA controller
LCD Controller	Configurable LCD controller with passive and active matrix LCD panel support

Table 1-1. TM4C129XKCZAD Microcontroller Features (*continued*)

Feature	Description
General-Purpose Timer (GPTM)	Eight 16/32-bit GPTM blocks
Watchdog Timer (WDT)	Two watchdog timers
Hibernation Module (HIB)	Low-power battery-backed Hibernation module
General-Purpose Input/Output (GPIO)	18 physical GPIO blocks
Advanced Motion Control	
Pulse Width Modulator (PWM)	One PWM module, with four PWM generator blocks and a control block, for a total of 8 PWM outputs.
Quadrature Encoder Interface (QEI)	One QEI module
Analog Support	
Analog-to-Digital Converter (ADC)	Two 12-bit ADC modules, each with a maximum sample rate of one million samples/second
Analog Comparator Controller	Three independent integrated analog comparators
Digital Comparator	16 digital comparators
System Management	
1-Wire	One 1-Wire module
JTAG and Serial Wire Debug (SWD)	One JTAG module with integrated ARM SWD
Package Information	
Package	212-ball BGA
Operating Range (Ambient)	Industrial (-40°C to 85°C) temperature range Extended (-40°C to 105°C) temperature range

Figure 1-1 on page 60 shows the features on the TM4C129XKCZAD microcontroller. Note that there are two on-chip buses that connect the core to the peripherals. The Advanced Peripheral Bus (APB) bus is the legacy bus. The Advanced High-Performance Bus (AHB) bus provides better back-to-back access performance than the APB bus.

Figure 1-1. Tiva™ TM4C129XKCZAD Microcontroller High-Level Block Diagram

1.3 TM4C129XKCZAD Microcontroller Features

The TM4C129XKCZAD microcontroller component features and general function are discussed in more detail in the following section.

1.3.1 ARM Cortex-M4F Processor Core

All members of the Tiva™ C Series, including the TM4C129XKCZAD microcontroller, are designed around an ARM Cortex-M processor core. The ARM Cortex-M processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

1.3.1.1 Processor Core (see page 89)

- 32-bit ARM Cortex-M4F architecture optimized for small-footprint embedded applications
- 120-MHz operation; 150 DMIPS performance
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
 - Single-cycle multiply instruction and hardware divide
 - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
 - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing

- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage up to specific frequencies; see “Internal Memory” on page 630 for more information.
- Ultra-low power consumption with integrated sleep modes

1.3.1.2 System Timer (SysTick) (see page 145)

ARM Cortex-M4F includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit, clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine
- A high-speed alarm timer using the system clock
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter
- A simple counter used to measure time to completion and time used
- An internal clock-source control based on missing/meeting durations

1.3.1.3 Nested Vectored Interrupt Controller (NVIC) (see page 146)

The TM4C129XKCZAD controller includes the ARM Nested Vectored Interrupt Controller (NVIC). The NVIC and Cortex-M4F prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The interrupt vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, meaning that back-to-back interrupts can be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 109 interrupts.

- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining (these values reflect no FPU stacking)
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications
- Dynamically reprioritizable interrupts
- Exceptional interrupt handling via hardware implementation of required register manipulations

1.3.1.4 System Control Block (SCB) (see page 147)

The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

1.3.1.5 Memory Protection Unit (MPU) (see page 147)

The MPU supports the standard ARM7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

1.3.1.6 Floating-Point Unit (FPU) (see page 152)

The FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined multiply and accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

1.3.2 On-Chip Memory

The TM4C129XKCZAD microcontroller is integrated with the following set of on-chip memory and features:

- 256 KB single-cycle SRAM
- 512 KB Flash memory
- 6KB EEPROM
- Internal ROM loaded with TivaWare™ for C Series software:
 - TivaWare™ Peripheral Driver Library
 - TivaWare Boot Loader
 - Advanced Encryption Standard (AES) cryptography tables
 - Cyclic Redundancy Check (CRC) error detection functionality

1.3.2.1 SRAM (see page 632)

The TM4C129XKCZAD microcontroller provides 256 KB of single-cycle on-chip SRAM. The internal SRAM of the device is located at offset 0x2000.0000 of the device memory map.

The SRAM is implemented using four 32-bit wide interleaving SRAM banks (separate SRAM arrays) which allow for increased speed between memory accesses. The SRAM memory provides nearly 2 GB/s memory bandwidth at a 120 MHz clock frequency.

Because read-modify-write (RMW) operations are very time consuming, ARM has introduced *bit-banding* technology in the Cortex-M4F processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

Data can be transferred to and from SRAM by the following masters:

- μDMA
- USB
- LCD Controller

- Ethernet Controller

1.3.2.2 Flash Memory (see page 634)

The TM4C129XKCZAD microcontroller provides 512 KB of on-chip Flash memory. The Flash memory is configured as four banks of 8 K x 128 bits (4 * 128 KB total) which are two-way interleaved. Memory blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

The TM4C129XKCZAD microcontroller provides enhanced performance and power savings by implementation of two sets of instruction prefetch buffers. Each prefetch buffer is 2 x 256 bits and can be combined as a 4 x 256-bit prefetch buffer.

The Flash can also be accessed by the µDMA in Run Mode.

1.3.2.3 ROM (see page 632)

The TM4C129XKCZAD ROM is preprogrammed with the following software and programs:

- TivaWare Peripheral Driver Library
- TivaWare Boot Loader
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error-detection functionality

The TivaWare Peripheral Driver Library is a royalty-free software library for controlling on-chip peripherals with a boot-loader capability. The library performs both peripheral initialization and control functions, with a choice of polled or interrupt-driven peripheral support. In addition, the library is designed to take full advantage of the stellar interrupt performance of the ARM Cortex-M4F core. No special pragmas or custom assembly code prologue/epilogue functions are required. For applications that require in-field programmability, the royalty-free TivaWare Boot Loader can act as an application loader and support in-field firmware updates.

The Advanced Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government. AES is a strong encryption method with reasonable performance and size. In addition, it is fast in both hardware and software, is fairly easy to implement, and requires little memory. The Texas Instruments encryption package is available with full source code, and is based on Lesser General Public License (LGPL) source. An LGPL means that the code can be used within an application without any copyleft implications for the application (the code does not automatically become open source). Modifications to the package source, however, must be open source.

CRC (Cyclic Redundancy Check) is a technique to validate a span of data has the same contents as when previously checked. This technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (for example, XOR all bits) because it catches changes more readily.

Note: CRC and AES software programs are available in the TivaWare™ for C Series software for backward-compatibility. A device that has enhanced CRC and AES integrated modules should utilize this hardware for best performance. Please refer to "Cyclical Redundancy

Check (CRC)" on page 975 and "Advance Encryption Standard Accelerator (AES)" on page 984 for more information.

1.3.2.4 EEPROM (see page 645)

The TM4C129XKCZAD microcontroller includes an EEPROM with the following features:

- 6Kbytes of memory accessible as 1536 32-bit words
- 96 blocks of 16 words (64 bytes) each
- Built-in wear leveling
- Access protection per block
- Lock protection option for the whole peripheral as well as per block using 32-bit to 96-bit unlock codes (application selectable)
- Interrupt support for write completion to avoid polling
- Endurance of 500K writes (when writing at fixed offset in every alternate page in circular fashion) to 15M operations (when cycling through two pages) per each 2-page block.

1.3.3 External Peripheral Interface (see page 844)

The External Peripheral Interface (EPI) provides access to external devices using a parallel path. Unlike communications peripherals such as SSI, UART, and I²C, the EPI is designed to act like a bus to external peripherals and memory.

The EPI has the following features:

- 8/16/32-bit dedicated parallel bus for external peripherals and memory
- Memory interface supports contiguous memory access independent of data bus width, thus enabling code execution directly from SDRAM, SRAM and Flash memory
- Blocking and non-blocking reads
- Separates processor from timing details through use of an internal write FIFO
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for read and write
 - Read channel request asserted by programmable levels on the internal Non-Blocking Read FIFO (NBRFIFO)
 - Write channel request asserted by empty on the internal Write FIFO (WFIFO)

The EPI supports three primary functional modes: Synchronous Dynamic Random Access Memory (SDRAM) mode, Traditional Host-Bus mode, and General-Purpose mode. The EPI module also provides custom GPIOs; however, unlike regular GPIOs, the EPI module uses a FIFO in the same way as a communication mechanism and is speed-controlled using clocking.

- Synchronous Dynamic Random Access Memory (SDRAM) mode
 - Supports x16 (single data rate) SDRAM at up to 60 MHz

- Supports low-cost SDRAMs up to 64 MB (512 megabits)
 - Includes automatic refresh and access to all banks/rows
 - Includes a Sleep/Standy mode to keep contents active with minimal power draw
 - Multiplexed address/data interface for reduced pin count
- Host-Bus mode
 - Traditional x8 and x16 MCU bus interface capabilities
 - Similar device compatibility options as PIC, ATmega, 8051, and others
 - Access to SRAM, NOR Flash memory, and other devices, with up to 1 MB of addressing in non-multiplexed mode and 256 MB in multiplexed mode (512 MB in Host-Bus 16 mode with no byte selects)
 - Support for up to 512 Mb PSRAM in quad chip select mode, with dedicated configuration register read and write enable.
 - Support of both muxed and de-muxed address and data
 - Access to a range of devices supporting the non-address FIFO x8 and x16 interface variant, with support for external FIFO (XFIFO) EMPTY and FULL signals
 - Speed controlled, with read and write data wait-state counters
 - Support for read/write burst mode to Host Bus
 - Multiple chip select modes including single, dual, and quad chip selects, with and without ALE
 - External iRDY signal provided for stall capability of reads and writes
 - Manual chip-enable (or use extra address pins)
- General-Purpose mode
 - Wide parallel interfaces for fast communications with CPLDs and FPGAs
 - Data widths up to 32 bits
 - Data rates up to 150 MB/second
 - Optional "address" sizes from 4 bits to 20 bits
 - Optional clock output, read/write strobes, framing (with counter-based size), and clock-enable input
- General parallel GPIO
 - 1 to 32 bits, FIFOed with speed control
 - Useful for custom peripherals or for digital data acquisition and actuator controls

1.3.4 Cyclical Redundancy Check (CRC) (see page 975)

The TM4C129XKCZAD microcontroller includes a CRC computation module for uses such as message transfer and safety system checks. This module can be used in conjunction with the AES and DES modules. The CRC has the following features:

- Support four major CRC forms:
 - CRC16-CCITT as used by CCITT/ITU X.25
 - CRC16-IBM as used by USB and ANSI
 - CRC32-IEEE as used by IEEE802.3 and MPEG2
 - CRC32C as used by G.Hn
- Allows word and byte feed
- Supports auto-initialization and manual initialization
- Supports MSb and LSb
- Supports CCITT post-processing
- Can be fed by µDMA, Flash memory and code

1.3.5 Advanced Encryption Standard (AES) Accelerator (see page 984)

The advanced encryption standard (AES) accelerator module provides hardware-accelerated data encryption and decryption operations based on a binary key. The AES module is a symmetrical cipher modules that supports a 128-bit, 192-bit, or 256-bit key in hardware for both encryption and decryption.

The AES has following features:

- Support for basic AES encrypt and decrypt operations:
 - Galois/Counter Mode (GCM), with basic GHASH operation
 - Counter Mode with CBC-MAC (CCM)
 - XTS Mode
- Availability of the following feedback operating modes:
 - Electronic Code Book Mode (ECB)
 - Cipher Block Chaining Mode (CBC)
 - Counter Mode (CTR)
 - Cipher Feedback Mode (CFB), 128-bit
 - F8 Mode
- Key sizes 128-, 192- and 256-bits

- Support for CBC_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for μ DMA transfers
- Fully synchronous design

1.3.6 Data Encryption Standard (DES) Accelerator (see page 1036)

The DES module provides hardware accelerated data encryption and decryption functions. The module runs either the single DES or the triple DES (3DES) algorithm and supports electronic codebook (ECB), cipher block chaining (CBC), and cipher feedback (CFB) modes of operation.

The DES accelerator includes the following main features:

- DES/3DES encryption and decryption.
- Feedback modes: ECB, CBC, CFB
- Host interrupt or μ DMA driven modes of operation. μ DMA support for data and context in/result out
- Fully synchronous design
- Internal wide-bus interface

1.3.7 Secure Hash Algorithm / Message Digest Algorithm (SHA/MD5) (see page 1065)

The SHA/MD5 module provides hardware-accelerated hash functions and can run:

- MD5 message digest algorithm developed by Ron Rivest in 1991
- SHA-1 algorithm compliant with the [FIPS 180-3 standard](#)
- SHA-2 (SHA-224 and SHA-256) algorithm compliant with the FIPS 180-3 standard
- Hash message authentication code (HMAC) operation

The algorithms produce a condensed representation of a message or a data file which can then be used to verify the message integrity.

The SHA/MD5 accelerator module includes the following main features:

- Hashing of 0 to $2^{33} - 2$ bytes of data (of which $2^{32} - 1$ bytes are in one pass) using the MD5, SHA-1, SHA-224, or SHA-256 hash algorithm (byte granularity only, no support for bit granularity)
- Automatic HMAC key preprocessing for HMAC keys up to 64 bytes
- Host-assisted HMAC key preprocessing for HMAC keys larger than 64 bytes
- HMAC from precomputes (inner/outer digest) for improved performance on small blocks
- Supports μ DMA operation for data and context in/result out transfers
- Supports interrupt to read the digest (signature)

1.3.8 Serial Communications Peripherals

The TM4C129XKCZAD controller supports both asynchronous and synchronous serial communications with:

- 10/100 Ethernet MAC with Advanced IEEE 1588 PTP hardware and both Media Independent Interface (MII) and Reduced MII (RMII) support; integrated PHY provided
- Two CAN 2.0 A/B controllers
- USB 2.0 Controller OTG/Host/Device with optional high speed using external PHY through ULPI interface
- Eight UARTs with IrDA, 9-bit and ISO 7816 support.
- 1-Wire Master module with the capability of providing power and data over a single bi-directional wire
- Ten I²C modules with four transmission speeds including high-speed mode
- Four Quad Synchronous Serial Interface modules (QSSI) with bi- and quad-SSI support

The following sections provide more detail on each of these communications functions.

1.3.8.1 Ethernet MAC and PHY (see page 1583)

The TM4C129XKCZAD Ethernet Controller consists of a fully integrated media access controller (MAC) and network physical (PHY) interface with the following features:

- Conforms to the IEEE 802.3 specification
 - 10BASE-T/100BASE-TX IEEE-802.3 compliant
 - Supports 10/100 Mbps data transmission rates
 - Supports full-duplex and half-duplex (CSMA/CD) operation
 - Supports flow control and back pressure
 - Full-featured and enhanced auto-negotiation
 - Supports IEEE 802.1Q VLAN tag detection
- Conforms to IEEE 1588-2002 Timestamp Precision Time Protocol (PTP) protocol and the IEEE 1588-2008 Advanced Timestamp specification
 - Transmit and Receive frame time stamping
 - Precision Time Protocol
 - Flexible pulse per second output
 - Supports coarse and fine correction methods
- Multiple addressing modes
 - Four MAC address filters

- Programmable 64-bit Hash Filter for multicast address filtering
- Promiscuous mode support
- Processor offloading
 - Programmable insertion (TX) or deletion (RX) of preamble and start-of-frame data
 - Programmable generation (TX) or deletion (RX) of CRC and pad data
 - IP header and hardware checksum checking (IPv4, IPv6, TCP/UDP/ICMP)
- Highly configurable
 - LED activity selection
 - Supports network statistics with RMON/MIB counters
 - Supports Magic Packet and wakeup frames
- Efficient transfers using integrated Direct Memory Access (DMA)
 - Dual-buffer (ring) or linked-list (chained) descriptors
 - Round-robin or fixed priority arbitration between TX/RX
 - Descriptors support up to 8 kB transfer blocks size
 - Programmable interrupts for flexible system implementation
- Physical media manipulation
 - MDI/MDI-X cross-over support
 - Register-programmable transmit amplitude
 - Automatic polarity correction and 10BASE-T signal reception
- MII and RMII interface support

1.3.8.2 Controller Area Network (CAN) (see page 1532)

Controller Area Network (CAN) is a multicast shared serial-bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or twisted-pair wire. Originally created for automotive purposes, it is now used in many embedded control applications (for example, industrial or medical). Bit rates up to 1 Mbps are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500m).

A transmitter sends a message to all CAN nodes (broadcasting). Each node decides on the basis of the identifier received whether it should process the message. The identifier also determines the priority that the message enjoys in competition for bus access. Each CAN message can transmit from 0 to 8 bytes of user information.

The TM4C129XKCZAD microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B

- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CANnTX and CANnRX signals

1.3.8.3 Universal Serial Bus (USB) (see page 1836)

Universal Serial Bus (USB) is a serial bus standard designed to allow peripherals to be connected and disconnected using a standardized interface without rebooting the system.

The TM4C129XKCZAD microcontroller has one USB controller that supports high and full speed multi-point communications and complies with the USB 2.0 standard for high-speed function. The USB controller can have three configurations: USB Device, USB Host, and USB On-The-Go (negotiated on-the-go as host or device when connected to other USB-enabled systems). Support for full-speed communication is provided by using the integrated USB PHY or optionally, a high-speed ULPI interface can communicate to an external PHY.

The USB module has the following features:

- Complies with USB-IF (Implementer's Forum) certification standards
- USB 2.0 high-speed (480 Mbps) operation with the integrated ULPI interface communicating with an external PHY
- Link Power Management support which uses link-state awareness to reduce power usage
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
 - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
 - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop detection and interrupt
- Integrated USB DMA with bus master capability
 - Up to eight RX Endpoint channels and up to eight TX Endpoint channels are available.
 - Each channel can be separately programmed to operate in different modes
 - Incremental burst transfers of 4-, 8-, 16- or unspecified length supported

1.3.8.4 UART (see page 1307)

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The TM4C129XKCZAD microcontroller includes eight fully programmable 16C550-type UARTs. Although the functionality is similar to a 16C550 UART, this UART design is not register compatible. The UART can generate individually masked interrupts from the Rx, Tx, modem flow control, modem status, and error conditions. The module generates a single combined interrupt when any of the interrupts are asserted and are unmasked.

The eight UARTs have the following features:

- Programmable baud-rate generator allowing speeds up to 7.5 Mbps for regular speed (divide by 16) and 15 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
 - 5, 6, 7, or 8 data bits
 - Even, odd, stick, or no-parity bit generation/detection
 - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
 - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
 - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
 - Support of normal 3/16 and low-power (1.41-2.23 μ s) bit durations
 - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem functionality available on the following UARTs:
 - UART0 (modem flow control and modem status)
 - UART1 (modem flow control and modem status)
 - UART2 (modem flow control)

- UART3 (modem flow control)
- UART4 (modem flow control)
- EIA-485 9-bit support
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive
 - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
 - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock

1.3.8.5 1-Wire Master Module (see page 1503)

1-Wire is a bi-directional serial communication protocol which provides both power and data over a single wire. The 1-Wire Master module can interface with a multiple variety of slaves such as thermometers, mixed-signal devices, memory, and authentication devices.

The TM4C129XKCZAD microcontroller includes a 1-Wire Master module with the following features:

- Support for standard and overdrive speeds, including a late-sample mechanism
- Allows transfers of send, receive and bi-directional bits
- Data size transfers of 1, 2, 3, or 4 bytes with sub-byte search and enumeration support
- Interrupt capability for transaction pacing and line error
- Optional two-wire support for isolated lines and high voltage use
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)

1.3.8.6 I²C (see page 1422)

The Inter-Integrated Circuit (I²C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL). The I²C bus interfaces to external I²C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I²C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

Each device on the I²C bus can be designated as either a master or a slave. I²C module supports both sending and receiving data as either a master or a slave and can operate simultaneously as both a master and a slave. Both the I²C master and slave can generate interrupts.

The TM4C129XKCZAD microcontroller includes I²C modules with the following features:

- Devices on the I²C bus can be designated as either a master or a slave

- Supports both transmitting and receiving data as either a master or a slave
- Supports simultaneous master and slave operation
- Four I²C modes
 - Master transmit
 - Master receive
 - Slave transmit
 - Slave receive
- Two 8-entry FIFOs for receive and transmit data
 - FIFOs can be independently assigned to master or slave
- Four transmission speeds:
 - Standard (100 Kbps)
 - Fast-mode (400 Kbps)
 - Fast-mode plus (1 Mbps)
 - High-speed mode (3.33 Mbps)
- Glitch suppression
- SMBus support through software
 - Clock low timeout interrupt
 - Dual slave address capability
 - Quick command capability
- Master and slave interrupt generation
 - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)
 - Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive
 - Ability to execute single data transfers or burst data transfers using the RX and TX FIFOs in the I²C

1.3.8.7 QSSI (see page 1373)

Quad Synchronous Serial Interface (QSSI) is a bi-directional communications interface that converts data between parallel and serial. The QSSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral device. The QSSI module can be configured as either a master or slave device. As a slave device, the QSSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices. The TX and RX paths are buffered with separate internal FIFOs.

The QSSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the QSSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

The TM4C129XKCZAD microcontroller includes four QSSI modules with the following features:

- Four QSSI channels with Advanced, Bi- and Quad-SSI functionality
- Programmable interface operation for Freescale SPI or Texas Instruments synchronous serial interfaces in Legacy Mode. Support for Freescale interface in Bi- and Quad-SSI mode.
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive
 - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
 - Transmit single request asserted when there is space in the FIFO; burst request asserted when four or more entries are available to be written in the FIFO
 - Maskable μ DMA interrupts for receive and transmit complete
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock.

1.3.9 System Integration

The TM4C129XKCZAD microcontroller provides a variety of standard system functions integrated into the device, including:

- Direct Memory Access Controller (DMA)
- System control and clocks including on-chip precision 16-MHz oscillator
- Eight 32-bit timers (each of which can be configured as two 16-bit timers)

- Lower-power battery-backed Hibernation module
- Real-Time Clock in Hibernation module
- Two Watchdog Timers
 - One timer runs off the main oscillator
 - One timer runs off the precision internal oscillator
- Up to 140 GPIOs, depending on configuration
 - Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
 - Independently configurable to 2-, 4-, 8-, 10-, or 12-mA drive capability
 - Up to 4 GPIOs can have 18-mA drive capability

The following sections provide more detail on each of these functions.

1.3.9.1 Direct Memory Access (see page 705)

The TM4C129XKCZAD microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA (μ DMA). The μ DMA controller provides a way to offload data transfer tasks from the Cortex-M4F processor, allowing for more efficient use of the processor and the available bus bandwidth. The μ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The μ DMA controller provides the following features:

- ARM PrimeCell® 32-channel configurable μ DMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
 - Basic for simple transfer scenarios
 - Ping-pong for continuous data flow
 - Scatter-gather for a programmable list of up to 256 arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
 - Independently configured and operated channels
 - Dedicated channels for supported on-chip modules
 - Flexible channel assignments
 - One channel each for receive and transmit path for bidirectional modules
 - Dedicated channel for software-initiated transfers
 - Per-channel configurable priority scheme
 - Optional software-initiated requests for any channel
- Two levels of priority

- Design optimizations for improved bus access performance between µDMA controller and the processor core
 - µDMA controller access is subordinate to core access
 - RAM striping
 - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable peripheral requests
- Interrupt on transfer completion, with a separate interrupt per channel

1.3.9.2 System Control and Clocks (see page 230)

System control determines the overall operation of the device. It provides information about the device, controls power-saving features, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

- Device identification information: version, part number, SRAM size, Flash memory size, and so on
- Power control
 - On-chip fixed Low Drop-Out (LDO) voltage regulator
 - Hibernation module handles the power-up/down 3.3 V sequencing and control for the core digital logic and analog circuits
 - Low-power options for microcontroller: Sleep and Deep-Sleep modes with clock gating
 - Low-power options for on-chip modules: software controls shutdown of individual peripherals and memory
 - 3.3-V supply brown-out detection and reporting via interrupt or reset
- Multiple clock sources for microcontroller system clock. The TM4C129XKCZAD microcontroller is clocked by the system clock (SYSCLK) that is distributed to the processor and integrated peripherals after clock gating. The SYSCLK frequency is based on the frequency of the clock source and a divisor factor. A PLL is provided for the generation of system clock frequencies in excess of the reference clock provided. The reference clocks for the PLL are the PIOSC and the main crystal oscillator. The following clock sources are provided to the TM4C129XKCZAD microcontroller:
 - 16-MHz Precision Oscillator (PIOSC)
 - Main Oscillator (MOSC): A frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins.

- Low Frequency Internal Oscillator (LFIOSC): On-chip resource used during power-saving modes
- Hibernate RTC oscillator (RTCOSC) clock that can be configured to be the 32.768-kHz external oscillator source from the Hibernation (HIB) module or the HIB Low Frequency clock source (HIB LFIOSC), which is located within the Hibernation Module.
- Flexible reset sources
 - Power-on reset (POR)
 - Reset pin assertion
 - Brown-out reset (BOR) detector alerts to system power drops
 - Software reset
 - Watchdog timer reset
 - Hibernation module event
 - MOSC failure

1.3.9.3 Programmable Timers (see page 1100)

Programmable timers can be used to count or time external events that drive the Timer input pins. Each 16/32-bit GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions and DMA transfers.

The General-Purpose Timer Module (GPTM) contains eight 16/32-bit GPTM blocks with the following functional options:

- Operating modes:
 - 16- or 32-bit programmable one-shot timer
 - 16- or 32-bit programmable periodic timer
 - 16-bit general-purpose timer with an 8-bit prescaler
 - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
 - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
 - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
 - The System Clock or a global Alternate Clock (ALTCLK) resource can be used as timer clock source. The global ALTCLK can be:
 - PIOOSC
 - Hibernation Module Real-time clock output (RTCOSC)
 - Low-frequency internal oscillator (LFIOSC)

- Count up or down
- Sixteen 16/32-bit Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Dedicated channel for each timer
 - Burst request generated on timer interrupt

1.3.9.4 CCP Pins (see page 1108)

Capture Compare PWM pins (CCP) can be used by the General-Purpose Timer Module to time/count external events using the CCP pin as an input. Alternatively, the GPTM can generate a simple PWM output on the CCP pin.

The TM4C129XKCZAD microcontroller includes 16/32-bit CCP pins that can be programmed to operate in the following modes:

- Capture: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer captures and stores the current timer value when a programmed event occurs.
- Compare: The GP Timer is incremented/decremented by programmed events on the CCP input. The GP Timer compares the current value with a stored value and generates an interrupt when a match occurs.
- PWM: The GP Timer is incremented/decremented by the system clock. A PWM signal is generated based on a match between the counter value and a value stored in a match register and is output on the CCP pin.

1.3.9.5 Hibernation Module (HIB) (see page 561)

The Hibernation module provides logic to switch power off to the main processor and peripherals and to wake on external or time-based events. The Hibernation module includes power-sequencing logic and has the following features:

- 32-bit real-time seconds counter (RTC) with 1/32,768 second resolution and a 15-bit sub-seconds counter
 - 32-bit RTC seconds match register and a 15-bit sub seconds match for timed wake-up and interrupt generation with 1/32,768 second resolution
 - RTC predivider trim for making fine adjustments to the clock rate
- Hardware Calendar Function

- Year, Month, Day, Day of Week, Hours, Minutes, Seconds
- Four-year leap compensation
- 24-hour or AM/PM configuration
- Two mechanisms for power control
 - System power control using discrete external regulator
 - On-chip power control using internal switches under register control
- V_{DD} supplies power when valid, even if $V_{BAT} > V_{DD}$
- Dedicated pin for waking using an external signal
- Capability to configure external reset (\overline{RST}) pin and/or up to four GPIO port pins as wake source, with programmable wake level
- Tamper Functionality
 - Support for four tamper inputs
 - Configurable level, weak pull-up, and glitch filter
 - Configurable tamper event response
 - Logging of up to four tamper events
 - Optional BBRAM erase on tamper detection
 - Tamper wake from hibernate capability
 - Hibernation clock input failure detect with a switch to the internal oscillator on detection
- RTC operational and hibernation memory valid as long as V_{DD} or V_{BAT} is valid
- Low-battery detection, signaling, and interrupt generation, with optional wake on low battery
- GPIO pin state can be retained during hibernation
- Clock source from an internal low frequency oscillator (HIB LFIOSC) or a 32.768-kHz external crystal or oscillator
- Sixteen 32-bit words of battery-backed memory to save state during hibernation
- Programmable interrupts for:
 - RTC match
 - External wake
 - Low battery

1.3.9.6 Watchdog Timers (see page 1173)

A watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way. The TM4C129XKCZAD Watchdog Timer can generate an interrupt, a non-maskable interrupt, or a reset when a time-out value is reached. In addition, the Watchdog Timer is ARM FiRM-compliant and can be configured to generate an interrupt to the microcontroller on its first time-out, and to generate a reset signal on its second timeout. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

The TM4C129XKCZAD microcontroller has two Watchdog Timer modules: Watchdog Timer 0 uses the system clock for its timer clock; Watchdog Timer 1 uses the PIOSC as its timer clock. The Watchdog Timer module has the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

1.3.9.7 Programmable GPIOs (see page 769)

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections. The TM4C129XKCZAD GPIO module is comprised of 18 physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FiRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 0-140 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see “Signal Tables” on page 2032 for the signals available to each GPIO pin).

- Up to 140 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 3.3-V-tolerant in input configuration
- Advanced High Performance Bus accesses all ports:
 - Ports A-H and J; Ports K-N and P-T
- Fast toggle capable of a change every clock cycle for ports on AHB
- Programmable control for GPIO interrupts
 - Interrupt generation masking
 - Edge-triggered on rising, falling, or both
 - Level-sensitive on High or Low values
 - Per-pin interrupts available on Port P and Port Q

- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence or a μ DMA transfer
- Pin state can be retained during Hibernation mode; pins on port P can be programmed to wake on level in Hibernation mode
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
 - Weak pull-up or pull-down resistors
 - 2-mA, 4-mA, 6-mA, 8-mA, 10-mA and 12-mA pad drive for digital communication; up to four pads can sink 18-mA for high-current applications
 - Slew rate control for 8-mA, 10-mA and 12-mA pad drive
 - Open drain enables
 - Digital input enables

1.3.9.8 LCD Controller (see page 1845)

The TM4C129XKCZAD controller integrates an LCD Controller which supports the following features:

- Character-based panels
 - Support for two character panels (CS0 and CS1) with independent and programmable bus timing parameters when in asynchronous Hitachi, Motorola, and Intel modes
 - Support for one character panel (CS0) with programmable bus timing parameters when in synchronous Motorola and Intel modes
 - Can be used as a generic 16-bit address/data interleaved MPU bus master with no external stall
- Passive matrix LCD panels
 - Panel types including STN, DSTN, and C-DSTN
 - AC Bias Control
- Active matrix LCD panels
 - Panel types including TN TFT
 - 1, 2, 4, or 8 bits per pixel with palette RAM and 16 or 24 bits per pixel without palette RAM
- OLED Panels
 - Passive Matrix (PM OLED) with frame buffer and controller IC inside the panel
 - Active Matrix (AM OLED)
- Bus mastering capability from either system SRAM or EPI memory.

1.3.10 Advanced Motion Control

The TM4C129XKCZAD microcontroller provides motion control functions integrated into the device, including:

- Eight advanced PWM outputs for motion and energy applications
- Four fault inputs to promote low-latency shutdown
- One Quadrature Encoder Input (QEI)

The following provides more detail on these motion control functions.

1.3.10.1 PWM (see page 1929)

The TM4C129XKCZAD microcontroller contains one PWM module, with four PWM generator blocks and a control block, for a total of 8 PWM outputs. Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control. The TM4C129XKCZAD PWM module consists of four PWM generator block and a control block. Each PWM generator block contains one timer (16-bit down or up/down counter), two comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. Each PWM generator block produces two PWM signals that can either be independent signals or a single pair of complementary signals with dead-band delays inserted.

Each PWM generator has the following features:

- Four fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled
- One 16-bit counter
 - Runs in Down or Up/Down mode
 - Output frequency controlled by a 16-bit load value
 - Load value updates can be synchronized
 - Produces output signals at zero and load value
- Two PWM comparators
 - Comparator value updates can be synchronized
 - Produces output signals on match
- PWM signal generator
 - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
 - Produces two independent PWM signals
- Dead-band generator

- Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
- Can be bypassed, leaving input PWM signals unmodified
- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal
- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Extended PWM synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

1.3.10.2 QEI (see page 2008)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, the position, direction of rotation, and speed can be tracked. In addition, a third channel, or index signal, can be used to reset the position counter. The TM4C129XKCZAD quadrature encoder with index (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel. The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 30 MHz for a 120-MHz system).

The TM4C129XKCZAD microcontroller includes two QEI modules providing control of two motors at the same time with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
 - Index pulse
 - Velocity-timer expiration

- Direction change
- Quadrature error detection

1.3.11 Analog

The TM4C129XKCZAD microcontroller provides analog functions integrated into the device, including:

- Two 12-bit Analog-to-Digital Converters (ADC), with a total of 24 analog input channels and each with a sample rate of one million samples/second
- Three analog comparators
- On-chip voltage regulator

The following provides more detail on these analog functions.

1.3.11.1 ADC (see page 1198)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. The TM4C129XKCZAD ADC module features 12-bit conversion resolution and supports 24 input channels plus an internal temperature sensor. Four buffered sample sequencers allow rapid sampling of up to 24 analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. Each ADC module has a digital comparator function that allows the conversion value to be diverted to a comparison unit that provides eight digital comparators.

The TM4C129XKCZAD microcontroller provides two ADC modules, each with the following features:

- 24 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional, programmable phase delay
- Sample and hold window programmability
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
 - Controller (software)
 - Timers
 - Analog Comparators
 - PWM

- GPIO
- Hardware averaging of up to 64 samples
- Eight digital comparators
- Converter uses two external reference signals (VREFA+ and VREFA-) or VDDA and GND_A as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Dedicated channel for each sample sequencer
 - ADC module uses burst requests for DMA
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate ADC clock

1.3.11.2 Analog Comparators (see page 1913)

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result. The TM4C129XKCZAD microcontroller provides three independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The TM4C129XKCZAD microcontroller provides three independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
 - An individual external reference voltage
 - A shared single external reference voltage
 - A shared internal reference voltage

1.3.12 JTAG and ARM Serial Wire Debug (see page 217)

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging. Texas Instruments replaces the ARM SW-DP and JTAG-DP with the ARM Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module providing all the normal JTAG debug and test functionality plus real-time access to system

memory without halting the core or requiring any target resident code. The SWJ-DP interface has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, and EXTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
 - Serial Wire JTAG Debug Port (SWJ-DP)
 - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
 - Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
 - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
 - Embedded Trace Macrocell (ETM) for instruction trace capture
 - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

1.3.13 Packaging and Temperature

- 212-ball RoHS-compliant BGA package
- Industrial (-40°C to 85°C) ambient temperature range
- Extended (-40°C to 105°C) ambient temperature range

1.4 TM4C129XKCZAD Microcontroller Hardware Details

Details on the pins and package can be found in the following sections:

- “Pin Diagram” on page 2031
- “Signal Tables” on page 2032
- “Electrical Characteristics” on page 2099
- “Package Information” on page 2174

1.5 Kits

The Tiva™ C Series provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware and comprehensive documentation including hardware design files
- Evaluation Kits provide a low-cost and effective means of evaluating TM4C129XKCZAD microcontrollers before purchase

- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box

See the Tiva series website at <http://www.ti.com/tiva-c> for the latest tools available, or ask your distributor.

1.6 Support Information

For support on Tiva™ C Series products, contact the [TI Worldwide Product Information Center](#) nearest you.

2 The Cortex-M4F Processor

The ARM® Cortex™-M4F processor provides a high-performance, low-cost platform that meets the system requirements of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

- 32-bit ARM® Cortex™-M4F architecture optimized for small-footprint embedded applications
- 120-MHz operation; 150 DMIPS performance
- Outstanding processing performance combined with fast interrupt handling
- Thumb-2 mixed 16-/32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications
 - Single-cycle multiply instruction and hardware divide
 - Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
 - Unaligned data access, enabling data to be efficiently packed into memory
- IEEE754-compliant single-precision Floating-Point Unit (FPU)
- 16-bit SIMD vector processing unit
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system and memories
- Hardware division and fast digital-signal-processing orientated multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Memory protection unit (MPU) to provide a privileged mode for protected operating system functionality
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing
- Migration from the ARM7™ processor family for better performance and power efficiency
- Optimized for single-cycle Flash memory usage up to specific frequencies; see “Internal Memory” on page 630 for more information.
- Ultra-low power consumption with integrated sleep modes

The Tiva™ C Series microcontrollers builds on this core to bring high-performance 32-bit computing to cost-conscious applications requiring significant control processing and connectivity capabilities such as:

- Low power, hand-held smart devices
- Gaming equipment
- Network appliances and switches
- Home and commercial site monitoring and control
- Electronic point-of-sale (POS) machines
- Motion control
- Medical instrumentation
- Remote connectivity and monitoring
- Test and measurement equipment
- Factory automation
- Fire and security
- Smart Energy/Smart Grid solutions
- Intelligent lighting control
- Transportation

This chapter provides information on the Tiva™ C Series implementation of the Cortex-M4F processor, including the programming model, the memory model, the exception model, fault handling, and power management.

For technical details on the instruction set, see the Cortex™-M4 instruction set chapter in the ARM® Cortex™-M4 Devices Generic User Guide (*literature number [ARM DUI 0553A](#)*).

2.1 Block Diagram

The Cortex-M4F processor is built on a high-performance processor core, with a 3-stage pipeline Harvard architecture, making it ideal for demanding embedded applications. The processor delivers exceptional power efficiency through an efficient instruction set and extensively optimized design, providing high-end processing hardware including IEEE754-compliant single-precision floating-point computation, a range of single-cycle and SIMD multiplication and multiply-with-accumulate capabilities, saturating arithmetic and dedicated hardware division.

To facilitate the design of cost-sensitive devices, the Cortex-M4F processor implements tightly coupled system components that reduce processor area while significantly improving interrupt handling and system debug capabilities. The Cortex-M4F processor implements a version of the Thumb® instruction set based on Thumb-2 technology, ensuring high code density and reduced program memory requirements. The Cortex-M4F instruction set provides the exceptional performance expected of a modern 32-bit architecture, with the high code density of 8-bit and 16-bit microcontrollers.

The Cortex-M4F processor closely integrates a nested interrupt controller (NVIC), to deliver industry-leading interrupt performance. The TM4C129XKCZAD NVIC includes a non-maskable interrupt (NMI) and provides eight interrupt priority levels. The tight integration of the processor core and NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing interrupt latency. The hardware stacking of registers and the ability to suspend load-multiple and store-multiple operations further reduce interrupt latency. Interrupt handlers do not require any assembler stubs which removes code overhead from the ISRs. Tail-chaining optimization also significantly reduces the overhead when switching from one ISR to another. To optimize low-power designs, the NVIC integrates with the sleep modes, including Deep-sleep mode, which enables the entire device to be rapidly powered down.

Figure 2-1. CPU Block Diagram

2.2 Overview

2.2.1 System-Level Interface

The Cortex-M4F processor provides multiple interfaces using AMBA® technology to provide high-speed, low-latency memory accesses. The core supports unaligned data accesses and implements atomic bit manipulation that enables faster peripheral controls, system spinlocks, and thread-safe Boolean data handling.

The Cortex-M4F processor has a memory protection unit (MPU) that provides fine-grain memory control, enabling applications to implement security privilege levels and separate code, data and stack on a task-by-task basis.

2.2.2 Integrated Configurable Debug

The Cortex-M4F processor implements a complete hardware debug solution, providing high system visibility of the processor and memory through either a traditional JTAG port or a 2-pin Serial Wire Debug (SWD) port that is ideal for microcontrollers and other small package devices. The Tiva™ C Series implementation replaces the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the *ARM® Debug Interface V5 Architecture Specification* for details on SWJ-DP.

For system trace, the processor integrates an Instrumentation Trace Macrocell (ITM) alongside data watchpoints and a profiling unit. To enable simple and cost-effective profiling of the system trace events, a Serial Wire Viewer (SWV) can export a stream of software-generated messages, data trace, and profiling information through a single pin.

The Embedded Trace Macrocell (ETM) delivers unrivaled instruction trace capture in an area smaller than traditional trace units, enabling full instruction trace. For more details on the ARM ETM, see the *ARM® Embedded Trace Macrocell Architecture Specification*.

The Flash Patch and Breakpoint Unit (FPB) provides up to eight hardware breakpoint comparators that debuggers can use. The comparators in the FPB also provide remap functions for up to eight words of program code in the code memory region. This FPB enables applications stored in a read-only area of Flash memory to be patched in another area of on-chip SRAM or Flash memory. If a patch is required, the application programs the FPB to remap a number of addresses. When those addresses are accessed, the accesses are redirected to a remap table specified in the FPB configuration.

For more information on the Cortex-M4F debug capabilities, see the *ARM® Debug Interface V5 Architecture Specification*.

2.2.3 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M4F trace data from the ITM, and an off-chip Trace Port Analyzer, as shown in Figure 2-2 on page 92.

Figure 2-2. TPIU Block Diagram

2.2.4 Cortex-M4F System Component Details

The Cortex-M4F includes the following system components:

- **SysTick**

A 24-bit count-down timer that can be used as a Real-Time Operating System (RTOS) tick timer or as a simple counter (see “System Timer (SysTick)” on page 145).

- **Nested Vectored Interrupt Controller (NVIC)**

An embedded interrupt controller that supports low latency interrupt processing (see “Nested Vectored Interrupt Controller (NVIC)” on page 146).

- System Control Block (SCB)

The programming model interface to the processor. The SCB provides system implementation information and system control, including configuration, control, and reporting of system exceptions (see “System Control Block (SCB)” on page 147).

- Memory Protection Unit (MPU)

Improves system reliability by defining the memory attributes for different memory regions. The MPU provides up to eight different regions and an optional predefined background region (see “Memory Protection Unit (MPU)” on page 147).

- Floating-Point Unit (FPU)

Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square-root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions (see “Floating-Point Unit (FPU)” on page 152).

2.3 Programming Model

This section describes the Cortex-M4F programming model. In addition to the individual core register descriptions, information about the processor modes and privilege levels for software execution and stacks is included.

2.3.1 Processor Mode and Privilege Levels for Software Execution

The Cortex-M4F has two modes of operation:

- Thread mode

Used to execute application software. The processor enters Thread mode when it comes out of reset.

- Handler mode

Used to handle exceptions. When the processor has finished exception processing, it returns to Thread mode.

In addition, the Cortex-M4F has two privilege levels:

- Unprivileged

In this mode, software has the following restrictions:

- Limited access to the `MSR` and `MRS` instructions and no use of the `CPS` instruction
- No access to the system timer, NVIC, or system control block
- Possibly restricted access to memory or peripherals

- Privileged

In this mode, software can use all the instructions and has access to all resources.

In Thread mode, the **CONTROL** register (see page 108) controls whether software execution is privileged or unprivileged. In Handler mode, software execution is always privileged.

Only privileged software can write to the **CONTROL** register to change the privilege level for software execution in Thread mode. Unprivileged software can use the **SVC** instruction to make a supervisor call to transfer control to privileged software.

2.3.2 Stacks

The processor uses a full descending stack, meaning that the stack pointer indicates the last stacked item on the memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory location. The processor implements two stacks: the main stack and the process stack, with a pointer for each held in independent registers (see the **SP** register on page 98).

In Thread mode, the **CONTROL** register (see page 108) controls whether the processor uses the main stack or the process stack. In Handler mode, the processor always uses the main stack. The options for processor operations are shown in Table 2-1 on page 94.

Table 2-1. Summary of Processor Mode, Privilege Level, and Stack Use

Processor Mode	Use	Privilege Level	Stack Used
Thread	Applications	Privileged or unprivileged ^a	Main stack or process stack ^a
Handler	Exception handlers	Always privileged	Main stack

a. See **CONTROL** (page 108).

2.3.3 Register Map

Figure 2-3 on page 95 shows the Cortex-M4F register set. Table 2-2 on page 95 lists the Core registers. The core registers are not memory mapped and are accessed by register name, so the base address is n/a (not applicable) and there is no offset.

Figure 2-3. Cortex-M4F Register Set**Table 2-2. Processor Register Map**

Offset	Name	Type	Reset	Description	See page
-	R0	RW	-	Cortex General-Purpose Register 0	97
-	R1	RW	-	Cortex General-Purpose Register 1	97
-	R2	RW	-	Cortex General-Purpose Register 2	97
-	R3	RW	-	Cortex General-Purpose Register 3	97
-	R4	RW	-	Cortex General-Purpose Register 4	97
-	R5	RW	-	Cortex General-Purpose Register 5	97
-	R6	RW	-	Cortex General-Purpose Register 6	97
-	R7	RW	-	Cortex General-Purpose Register 7	97
-	R8	RW	-	Cortex General-Purpose Register 8	97
-	R9	RW	-	Cortex General-Purpose Register 9	97
-	R10	RW	-	Cortex General-Purpose Register 10	97
-	R11	RW	-	Cortex General-Purpose Register 11	97

Table 2-2. Processor Register Map (*continued*)

Offset	Name	Type	Reset	Description	See page
-	R12	RW	-	Cortex General-Purpose Register 12	97
-	SP	RW	-	Stack Pointer	98
-	LR	RW	0xFFFF.FFFF	Link Register	99
-	PC	RW	-	Program Counter	100
-	PSR	RW	0x0100.0000	Program Status Register	101
-	PRIMASK	RW	0x0000.0000	Priority Mask Register	105

-	CONTROL	RW	0x0000.0000	Control Register	108
-	FPSC	RW	-	Floating-Point Status Control	110

2.3.4 Register Descriptions

This section lists and describes the Cortex-M4F registers, in the order shown in Figure 2-3 on page 95. The core registers are not memory mapped and are accessed by register name rather than offset.

Note: The register type shown in the register descriptions refers to type during program execution in Thread mode and Handler mode. Debug access can differ.

- Register 1: Cortex General-Purpose Register 0 (R0)**
- Register 2: Cortex General-Purpose Register 1 (R1)**
- Register 3: Cortex General-Purpose Register 2 (R2)**
- Register 4: Cortex General-Purpose Register 3 (R3)**
- Register 5: Cortex General-Purpose Register 4 (R4)**
- Register 6: Cortex General-Purpose Register 5 (R5)**
- Register 7: Cortex General-Purpose Register 6 (R6)**
- Register 8: Cortex General-Purpose Register 7 (R7)**
- Register 9: Cortex General-Purpose Register 8 (R8)**
- Register 10: Cortex General-Purpose Register 9 (R9)**
- Register 11: Cortex General-Purpose Register 10 (R10)**
- Register 12: Cortex General-Purpose Register 11 (R11)**
- Register 13: Cortex General-Purpose Register 12 (R12)**

The **Rn** registers are 32-bit general-purpose registers for data operations and can be accessed from either privileged or unprivileged mode.

Cortex General-Purpose Register 0 (R0)

Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:0	DATA	RW	-	Register data.

Register 14: Stack Pointer (SP)

The **Stack Pointer (SP)** is register R13. In Thread mode, the function of this register changes depending on the **ASP** bit in the **Control Register (CONTROL)** register. When the **ASP** bit is clear, this register is the **Main Stack Pointer (MSP)**. When the **ASP** bit is set, this register is the **Process Stack Pointer (PSP)**. On reset, the **ASP** bit is clear, and the processor loads the **MSP** with the value from address 0x0000.0000. The **MSP** can only be accessed in privileged mode; the **PSP** can be accessed in either privileged or unprivileged mode.

Stack Pointer (SP)

Type RW, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SP															
Type	RW															
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SP															
Type	RW															
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	SP	RW	-	This field is the address of the stack pointer.
------	----	----	---	---

Register 15: Link Register (LR)

The **Link Register (LR)** is register R14, and it stores the return information for subroutines, function calls, and exceptions. The Link Register can be accessed from either privileged or unprivileged mode.

`EXC_RETURN` is loaded into the **LR** on exception entry. See Table 2-10 on page 133 for the values and description.

Link Register (LR)

Type RW, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	LINK	RW	0xFFFF.FFFF	This field is the return address.

Register 16: Program Counter (PC)

The **Program Counter (PC)** is register R15, and it contains the current program address. On reset, the processor loads the **PC** with the value of the reset vector, which is at address 0x0000.0004. Bit 0 of the reset vector is loaded into the **THUMB** bit of the **EPSR** at reset and must be 1. The **PC** register can be accessed in either privileged or unprivileged mode.

Program Counter (PC)

Type RW, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Type	RW															
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	RW															
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit/Field	Name	Type	Reset	Description
31:0	PC	RW	-	This field is the current program address.

Register 17: Program Status Register (PSR)

Note: This register is also referred to as **xPSR**.

The **Program Status Register (PSR)** has three functions, and the register bits are assigned to the different functions:

- **Application Program Status Register (APSR)**, bits 31:27, bits 19:16
- **Execution Program Status Register (EPSR)**, bits 26:24, 15:10
- **Interrupt Program Status Register (IPSR)**, bits 7:0

The **PSR**, **IPSR**, and **EPSR** registers can only be accessed in privileged mode; the **APSR** register can be accessed in either privileged or unprivileged mode.

APSR contains the current state of the condition flags from previous instruction executions.

EPSR contains the Thumb state bit and the execution state bits for the If-Then (**IT**) instruction or the Interruptible-Continuable Instruction (**ICI**) field for an interrupted load multiple or store multiple instruction. Attempts to read the **EPSR** directly through application software using the **MSR** instruction always return zero. Attempts to write the **EPSR** using the **MSR** instruction in application software are always ignored. Fault handlers can examine the **EPSR** value in the stacked **PSR** to determine the operation that faulted (see “Exception Entry and Return” on page 130).

IPSR contains the exception type number of the current Interrupt Service Routine (ISR).

These registers can be accessed individually or as a combination of any two or all three registers, using the register name as an argument to the **MRS** or **MSR** instructions. For example, all of the registers can be read using **PSR** with the **MRS** instruction, or **APSR** only can be written to using **APSR** with the **MSR** instruction. page 101 shows the possible register combinations for the **PSR**. See the **MRS** and **MSR** instruction descriptions in the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)* for more information about how to access the program status registers.

Table 2-3. PSR Register Combinations

Register	Type	Combination
PSR	RW ^{a, b}	APSR , EPSR , and IPSR
IEPSR	RO	EPSR and IPSR
IAPSR	RW ^a	APSR and IPSR
EAPSR	RW ^b	APSR and EPSR

a. The processor ignores writes to the **IPSR** bits.

b. Reads of the **EPSR** bits return zero, and the processor ignores writes to these bits.

Program Status Register (PSR)

Type RW, reset 0x0100.0000

Register 18: Priority Mask Register (PRIMASK)

The **PRIMASK** register prevents activation of all exceptions with programmable priority. Reset, non-maskable interrupt (NMI), and hard fault are the only exceptions with fixed priority. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The **MSR** and **MRS** instructions are used to access the **PRIMASK** register, and the **CPS** instruction may be used to change the value of the **PRIMASK** register. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 123.

Priority Mask Register (PRIMASK)

Type RW, reset 0x0000.0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	PRIMASK	RW	0	Priority Mask
		Value	Description	
		1	Prevents the activation of all exceptions with configurable priority.	
		0	No effect.	

Register 19: Fault Mask Register (FAULTMASK)

The **FAULTMASK** register prevents activation of all exceptions except for the Non-Maskable Interrupt (NMI). Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. The **MSR** and **MRS** instructions are used to access the **FAULTMASK** register, and the **CPS** instruction may be used to change the value of the **FAULTMASK** register. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide (literature number ARM DUI 0553A)* for more information on these instructions. For more information on exception priority levels, see “Exception Types” on page 123.

Fault Mask Register (FAULTMASK)

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	FAULTMASK	RW	0	Fault Mask
		Value	Description	
		1	Prevents the activation of all exceptions except for NMI.	
		0	No effect.	

The processor clears the **FAULTMASK** bit on exit from any exception handler except the NMI handler.

Register 20: Base Priority Mask Register (BASEPRI)

The **BASEPRI** register defines the minimum priority for exception processing. When **BASEPRI** is set to a nonzero value, it prevents the activation of all exceptions with the same or lower priority level as the **BASEPRI** value. Exceptions should be disabled when they might impact the timing of critical tasks. This register is only accessible in privileged mode. For more information on exception priority levels, see “Exception Types” on page 123.

Base Priority Mask Register (BASEPRI)

Type RW, reset 0x0000.0000

Value	Description																					
0x0	All exceptions are unmasked.																					
0x1	All exceptions with priority level 1-7 are masked.																					
0x2	All exceptions with priority level 2-7 are masked.																					
0x3	All exceptions with priority level 3-7 are masked.																					
0x4	All exceptions with priority level 4-7 are masked.																					
0x5	All exceptions with priority level 5-7 are masked.																					
0x6	All exceptions with priority level 6-7 are masked.																					
0x7	All exceptions with priority level 7 are masked.																					
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.																		

Register 21: Control Register (CONTROL)

The **CONTROL** register controls the stack used and the privilege level for software execution when the processor is in Thread mode, and indicates whether the FPU state is active. This register is only accessible in privileged mode.

Handler mode always uses the **MSP**, so the processor ignores explicit writes to the **ASP** bit of the **CONTROL** register when in Handler mode. The exception entry and return mechanisms automatically update the **CONTROL** register based on the **EXC_RETURN** value (see Table 2-10 on page 133). In an OS environment, threads running in Thread mode should use the process stack and the kernel and exception handlers should use the main stack. By default, Thread mode uses the **MSP**. To switch the stack pointer used in Thread mode to the **PSP**, either use the **MSR** instruction to set the **ASP** bit, as detailed in the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (*literature number ARM DUI 0553A*), or perform an exception return to Thread mode with the appropriate **EXC_RETURN** value, as shown in Table 2-10 on page 133.

Note: When changing the stack pointer, software must use an **ISB** instruction immediately after the **MSR** instruction, ensuring that instructions after the **ISB** execute use the new stack pointer. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (*literature number ARM DUI 0553A*).

Control Register (CONTROL)

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	FPCA	RW	0	Floating-Point Context Active
		Value	Description	
		1	Floating-point context active	
		0	No floating-point context active	
				The Cortex-M4F uses this bit to determine whether to preserve floating-point state when processing an exception.

Important: Two bits control when FPCA can be enabled: the **ASPEN** bit in the **Floating-Point Context Control (FPCC)** register and the **DISFPCA** bit in the **Auxiliary Control (ACTLR)** register.

Bit/Field	Name	Type	Reset	Description
1	ASP	RW	0	<p>Active Stack Pointer</p> <p>Value Description</p> <p>1 The PSP is the current stack pointer.</p> <p>0 The MSP is the current stack pointer</p> <p>In Handler mode, this bit reads as zero and ignores writes. The Cortex-M4F updates this bit automatically on exception return.</p>
0	TMPL	RW	0	<p>Thread Mode Privilege Level</p> <p>Value Description</p> <p>1 Unprivileged software can be executed in Thread mode.</p> <p>0 Only privileged software can be executed in Thread mode.</p>

Register 22: Floating-Point Status Control (FPSC)

The **FPSC** register provides all necessary user-level control of the floating-point system.

Floating-Point Status Control (FPSC)

Type RW, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

2.3.5 Exceptions and Interrupts

The Cortex-M4F processor supports interrupts and system exceptions. The processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. An exception changes the normal flow of software control. The processor uses Handler mode to handle all exceptions except for reset. See “Exception Entry and Return” on page 130 for more information.

The NVIC registers control interrupt handling. See “Nested Vectored Interrupt Controller (NVIC)” on page 146 for more information.

2.3.6 Data Types

The Cortex-M4F supports 32-bit words, 16-bit halfwords, and 8-bit bytes. The processor also supports 64-bit data transfer instructions. All instruction and data memory accesses are little endian. See “Memory Regions, Types and Attributes” on page 116 for more information.

2.4 Memory Model

This section describes the processor memory map, the behavior of memory accesses, and the bit-banding features. The processor has a fixed memory map that provides up to 4 GB of addressable memory.

The memory map for the TM4C129XKCZAD controller is provided in Table 2-4 on page 112. In this manual, register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map.

The regions for SRAM and peripherals include bit-band regions. Bit-banding provides atomic operations to bit data (see “Bit-Banding” on page 118).

The processor reserves regions of the Private peripheral bus (PPB) address range for core peripheral registers (see “Cortex-M4 Peripherals” on page 144).

Note: Within the memory map, attempts to read or write addresses in reserved spaces result in a bus fault. In addition, attempts to write addresses in the flash range also result in a bus fault.

Table 2-4. Memory Map

2.4.1 Memory Regions, Types and Attributes

The memory map and the programming of the MPU split the memory map into regions. Each region has a defined memory type, and some regions have additional memory attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

- Normal: The processor can re-order transactions for efficiency and perform speculative reads.
- Device: The processor preserves transaction order relative to other transactions to Device or Strongly Ordered memory.
- Strongly Ordered: The processor preserves transaction order relative to all other transactions.

The different ordering requirements for Device and Strongly Ordered memory mean that the memory system can buffer a write to Device memory but must not buffer a write to Strongly Ordered memory.

An additional memory attribute is Execute Never (XN), which means the processor prevents instruction accesses. A fault exception is generated only on execution of an instruction executed from an XN region.

2.4.2 Memory System Ordering of Memory Accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing the order does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions (see “Software Ordering of Memory Accesses” on page 117).

However, the memory system does guarantee ordering of accesses to Device and Strongly Ordered memory. For two memory access instructions A1 and A2, if both A1 and A2 are accesses to either Device or Strongly Ordered memory, and if A1 occurs before A2 in program order, A1 is always observed before A2.

2.4.3 Behavior of Memory Accesses

Table 2-5 on page 117 shows the behavior of accesses to each region in the memory map. See “Memory Regions, Types and Attributes” on page 116 for more information on memory types and the XN attribute. Tiva™ C Series devices may have reserved memory areas within the address ranges shown below (refer to Table 2-4 on page 112 for more information).

Table 2-5. Memory Access Behavior

Address Range	Memory Region	Memory Type	Execute Never (XN)	Description
0x0000.0000 - 0x1FFF.FFFF	Code	Normal	-	This executable region is for program code. Data can also be stored here.
0x2000.0000 - 0x3FFF.FFFF	SRAM	Normal	-	This executable region is for data. Code can also be stored here. This region includes bit band and bit band alias areas (see Table 2-6 on page 119).
0x4000.0000 - 0x5FFF.FFFF	Peripheral	Device	XN	This region includes bit band and bit band alias areas (see Table 2-7 on page 119).
0x6000.0000 - 0x9FFF.FFFF	External RAM	Normal	-	This executable region is for data.
0xA000.0000 - 0xDFFF.FFFF	External device	Device	XN	This region is for external device memory.
0xE000.0000-0xE00F.FFFF	Private peripheral bus	Strongly Ordered	XN	This region includes the NVIC, system timer, and system control block.
0xE010.0000- 0xFFFF.FFFF	Reserved	-	-	-

The Code, SRAM, and external RAM regions can hold programs. However, it is recommended that programs always use the Code region because the Cortex-M4F has separate buses that can perform instruction fetches and data accesses simultaneously.

The MPU can override the default memory access behavior described in this section. For more information, see “Memory Protection Unit (MPU)” on page 147.

The Cortex-M4F prefetches instructions ahead of execution and speculatively prefetches from branch target addresses.

2.4.4 Software Ordering of Memory Accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions for the following reasons:

- The processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence.
- The processor has multiple bus interfaces.
- Memory or devices in the memory map have different wait states.
- Some memory accesses are buffered or speculative.

“Memory System Ordering of Memory Accesses” on page 116 describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The Cortex-M4F has the following memory barrier instructions:

- The Data Memory Barrier (**DMB**) instruction ensures that outstanding memory transactions complete before subsequent memory transactions.
- The Data Synchronization Barrier (**DSB**) instruction ensures that outstanding memory transactions complete before subsequent instructions execute.
- The Instruction Synchronization Barrier (**ISB**) instruction ensures that the effect of all completed memory transactions is recognizable by subsequent instructions.

Memory barrier instructions can be used in the following situations:

- MPU programming
 - If the MPU settings are changed and the change must be effective on the very next instruction, use a `DSB` instruction to ensure the effect of the MPU takes place immediately at the end of context switching.
 - Use an `ISB` instruction to ensure the new MPU setting takes effect immediately after programming the MPU region or regions, if the MPU configuration code was accessed using a branch or call. If the MPU configuration code is entered using exception mechanisms, then an `ISB` instruction is not required.
- Vector table

If the program changes an entry in the vector table and then enables the corresponding exception, use a `DMB` instruction between the operations. The `DMB` instruction ensures that if the exception is taken immediately after being enabled, the processor uses the new exception vector.
- Self-modifying code

If a program contains self-modifying code, use an `ISB` instruction immediately after the code modification in the program. The `ISB` instruction ensures subsequent instruction execution uses the updated program.
- Memory map switching

If the system contains a memory map switching mechanism, use a `DSB` instruction after switching the memory map in the program. The `DSB` instruction ensures subsequent instruction execution uses the updated memory map.
- Dynamic exception priority change

When an exception priority has to change when the exception is pending or active, use `DSB` instructions after the change. The change then takes effect on completion of the `DSB` instruction.

Memory accesses to Strongly Ordered memory, such as the System Control Block, do not require the use of `DMB` instructions.

For more information on the memory barrier instructions, see the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)).

2.4.5 Bit-Banding

A bit-band region maps each word in a bit-band alias region to a single bit in the bit-band region. The bit-band regions occupy the lowest 1 MB of the SRAM and peripheral memory regions. Accesses to the 32-MB SRAM alias region map to the 1-MB SRAM bit-band region, as shown in Table 2-6 on page 119. Accesses to the 32-MB peripheral alias region map to the 1-MB peripheral bit-band region, as shown in Table 2-7 on page 119. For the specific address range of the bit-band regions, see Table 2-4 on page 112.

Note: A word access to the SRAM or the peripheral bit-band alias region maps to a single bit in the SRAM or peripheral bit-band region.

A word access to a bit band address results in a word access to the underlying memory, and similarly for halfword and byte accesses. This allows bit band accesses to match the access requirements of the underlying peripheral.

Table 2-6. SRAM Memory Bit-Banding Regions

Address Range		Memory Region	Instruction and Data Accesses
Start	End		
0x2000.0000	0x2006.FFFF	SRAM bit-band region	Direct accesses to this memory range behave as SRAM memory accesses, but this region is also bit addressable through bit-band alias.
0x2200.0000	0x2234.FFFF	SRAM bit-band alias	Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not remapped.

Table 2-7. Peripheral Memory Bit-Banding Regions

Address Range		Memory Region	Instruction and Data Accesses
Start	End		
0x4000.0000	0x400F.FFFF	Peripheral bit-band region	Direct accesses to this memory range behave as peripheral memory accesses, but this region is also bit addressable through bit-band alias.
0x4200.0000	0x43FF.FFFF	Peripheral bit-band alias	Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not permitted.

The following formula shows how the alias region maps onto the bit-band region:

$$\text{bit_word_offset} = (\text{byte_offset} \times 32) + (\text{bit_number} \times 4)$$

$$\text{bit_word_addr} = \text{bit_band_base} + \text{bit_word_offset}$$

where:

bit_word_offset

The position of the target bit in the bit-band memory region.

bit_word_addr

The address of the word in the alias memory region that maps to the targeted bit.

bit_band_base

The starting address of the alias region.

byte_offset

The number of the byte in the bit-band region that contains the targeted bit.

bit_number

The bit position, 0-7, of the targeted bit.

Figure 2-4 on page 120 shows examples of bit-band mapping between the SRAM bit-band alias region and the SRAM bit-band region:

- The alias word at 0x23FF.FFE0 maps to bit 0 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFE0 = 0x2200.0000 + (0x000F.FFFF * 32) + (0 * 4)$$

- The alias word at 0x23FF.FFFC maps to bit 7 of the bit-band byte at 0x200F.FFFF:

$$0x23FF.FFFC = 0x2200.0000 + (0x000F.FFFF * 32) + (7 * 4)$$

- The alias word at 0x2200.0000 maps to bit 0 of the bit-band byte at 0x2000.0000:

$$0x2200.0000 = 0x2200.0000 + (0 * 32) + (0 * 4)$$

- The alias word at 0x2200.001C maps to bit 7 of the bit-band byte at 0x2000.0000:

$$0x2200.001C = 0x2200.0000 + (0 * 32) + (7 * 4)$$

Figure 2-4. Bit-Band Mapping

2.4.5.1 Directly Accessing an Alias Region

Writing to a word in the alias region updates a single bit in the bit-band region.

Bit 0 of the value written to a word in the alias region determines the value written to the targeted bit in the bit-band region. Writing a value with bit 0 set writes a 1 to the bit-band bit, and writing a value with bit 0 clear writes a 0 to the bit-band bit.

Bits 31:1 of the alias word have no effect on the bit-band bit. Writing 0x01 has the same effect as writing 0xFF. Writing 0x00 has the same effect as writing 0x0E.

When reading a word in the alias region, 0x0000.0000 indicates that the targeted bit in the bit-band region is clear and 0x0000.0001 indicates that the targeted bit in the bit-band region is set.

2.4.5.2 Directly Accessing a Bit-Band Region

"Behavior of Memory Accesses" on page 116 describes the behavior of direct byte, halfword, or word accesses to the bit-band regions.

2.4.6 Data Storage

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word. Data is stored in little-endian format, with the least-significant byte (lsbyte) of a word stored at the

lowest-numbered byte, and the most-significant byte (msbyte) stored at the highest-numbered byte. Figure 2-5 on page 121 illustrates how data is stored.

Figure 2-5. Data Storage

2.4.7 Synchronization Primitives

The Cortex-M4F instruction set includes pairs of synchronization primitives which provide a non-blocking mechanism that a thread or process can use to obtain exclusive access to a memory location. Software can use these primitives to perform a guaranteed read-modify-write memory update sequence or for a semaphore mechanism.

Note: The available pairs of synchronization primitives are only available for single processor use and should not be used with multi-processor systems.

A pair of synchronization primitives consists of:

- A Load-Exclusive instruction, which is used to read the value of a memory location and requests exclusive access to that location.
- A Store-Exclusive instruction, which is used to attempt to write to the same memory location and returns a status bit to a register. If this status bit is clear, it indicates that the thread or process gained exclusive access to the memory and the write succeeds; if this status bit is set, it indicates that the thread or process did not gain exclusive access to the memory and no write was performed.

The pairs of Load-Exclusive and Store-Exclusive instructions are:

- The word instructions `LDREX` and `STREX`
- The halfword instructions `LDREXH` and `STREXH`
- The byte instructions `LDREXB` and `STREXB`

Software must use a Load-Exclusive instruction with the corresponding Store-Exclusive instruction.

To perform an exclusive read-modify-write of a memory location, software must:

1. Use a Load-Exclusive instruction to read the value of the location.
2. Modify the value, as required.
3. Use a Store-Exclusive instruction to attempt to write the new value back to the memory location.
4. Test the returned status bit.

If the status bit is clear, the read-modify-write completed successfully. If the status bit is set, no write was performed, which indicates that the value returned at step 1 might be out of date. The software must retry the entire read-modify-write sequence.

Software can use the synchronization primitives to implement a semaphore as follows:

1. Use a Load-Exclusive instruction to read from the semaphore address to check whether the semaphore is free.
2. If the semaphore is free, use a Store-Exclusive to write the claim value to the semaphore address.
3. If the returned status bit from step 2 indicates that the Store-Exclusive succeeded, then the software has claimed the semaphore. However, if the Store-Exclusive failed, another process might have claimed the semaphore after the software performed step 1.

The Cortex-M4F includes an exclusive access monitor that tags the fact that the processor has executed a Load-Exclusive instruction. The processor removes its exclusive access tag if:

- It executes a `CLREX` instruction.
- It executes a Store-Exclusive instruction, regardless of whether the write succeeds.
- An exception occurs, which means the processor can resolve semaphore conflicts between different threads.

For more information about the synchronization primitive instructions, see the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (literature number [ARM DUI 0553A](#)).

2.5 Exception Model

The ARM Cortex-M4F processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions in Handler Mode. The processor state is automatically stored to the stack on an exception and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, enabling efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 2-8 on page 124 lists all exception types. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 109 interrupts (listed in Table 2-9 on page 125).

Priorities on the system handlers are set with the NVIC **System Handler Priority n (SYSPRI_n)** registers. Interrupts are enabled through the NVIC **Interrupt Set Enable n (EN_n)** register and prioritized with the NVIC **Interrupt Priority n (PRI_n)** registers. Priorities can be grouped by splitting priority levels into preemption priorities and subpriorities. All the interrupt registers are described in “Nested Vectored Interrupt Controller (NVIC)” on page 146.

Internally, the highest user-programmable priority (0) is treated as fourth priority, after a Reset, Non-Maskable Interrupt (NMI), and a Hard Fault, in that order. Note that 0 is the default priority for all the programmable priorities.

Important: After a write to clear an interrupt source, it may take several processor cycles for the NVIC to see the interrupt source deassert. Thus if the interrupt clear is done as the last action in an interrupt handler, it is possible for the interrupt handler to complete while

the NVIC sees the interrupt as still asserted, causing the interrupt handler to be re-entered errantly. This situation can be avoided by either clearing the interrupt source at the beginning of the interrupt handler or by performing a read or write after the write to clear the interrupt source (and flush the write buffer).

See “Nested Vectored Interrupt Controller (NVIC)” on page 146 for more information on exceptions and interrupts.

2.5.1 Exception States

Each exception is in one of the following states:

- **Inactive.** The exception is not active and not pending.
- **Pending.** The exception is waiting to be serviced by the processor. An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending.
- **Active.** An exception that is being serviced by the processor but has not completed.
Note: An exception handler can interrupt the execution of another exception handler. In this case, both exceptions are in the active state.
- **Active and Pending.** The exception is being serviced by the processor, and there is a pending exception from the same source.

2.5.2 Exception Types

The exception types are:

- **Reset.** Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts as privileged execution in Thread mode.
- **NMI.** A non-maskable Interrupt (NMI) can be signaled using the NMI signal or triggered by software using the **Interrupt Control and State (INTCTRL)** register. This exception has the highest priority other than reset. NMI is permanently enabled and has a fixed priority of -2. NMIs cannot be masked or prevented from activation by any other exception or preempted by any exception other than reset.
- **Hard Fault.** A hard fault is an exception that occurs because of an error during exception processing, or because an exception cannot be managed by any other exception mechanism. Hard faults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority.
- **Memory Management Fault.** A memory management fault is an exception that occurs because of a memory protection related fault, including access violation and no match. The MPU or the fixed memory protection constraints determine this fault, for both instruction and data memory transactions. This fault is used to abort instruction accesses to Execute Never (XN) memory regions, even if the MPU is disabled.
- **Bus Fault.** A bus fault is an exception that occurs because of a memory-related fault for an instruction or data memory transaction such as a prefetch fault or a memory access fault. This fault can be enabled or disabled.

- **Usage Fault.** A usage fault is an exception that occurs because of a fault related to instruction execution, such as:
 - An undefined instruction
 - An illegal unaligned access
 - Invalid state on instruction execution
 - An error on exception return
 An unaligned address on a word or halfword memory access or division by zero can cause a usage fault when the core is properly configured.
- **SVCALL.** A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers.
- **Debug Monitor.** This exception is caused by the debug monitor (when not halting). This exception is only active when enabled. This exception does not activate if it is a lower priority than the current activation.
- **PendSV.** PendSV is a pendable, interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active. PendSV is triggered using the **Interrupt Control and State (INTCTRL)** register.
- **SysTick.** A SysTick exception is an exception that the system timer generates when it reaches zero when it is enabled to generate an interrupt. Software can also generate a SysTick exception using the **Interrupt Control and State (INTCTRL)** register. In an OS environment, the processor can use this exception as system tick.
- **Interrupt (IRQ).** An interrupt, or IRQ, is an exception signaled by a peripheral or generated by a software request and fed through the NVIC (prioritized). All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor. Table 2-9 on page 125 lists the interrupts on the TM4C129XKCZAD controller.

For an asynchronous exception, other than reset, the processor can execute another instruction between when the exception is triggered and when the processor enters the exception handler.

Privileged software can disable the exceptions that Table 2-8 on page 124 shows as having configurable priority (see the **SYSHNDCTRL** register on page 190 and the **DIS0** register on page 165).

For more information about hard faults, memory management faults, bus faults, and usage faults, see “Fault Handling” on page 133.

Table 2-8. Exception Types

Exception Type	Vector Number	Priority ^a	Vector Address or Offset ^b	Activation
-	0	-	0x0000.0000	Stack top is loaded from the first entry of the vector table on reset.
Reset	1	-3 (highest)	0x0000.0004	Asynchronous
Non-Maskable Interrupt (NMI)	2	-2	0x0000.0008	Asynchronous
Hard Fault	3	-1	0x0000.000C	-
Memory Management	4	programmable ^c	0x0000.0010	Synchronous

Table 2-8. Exception Types (continued)

Exception Type	Vector Number	Priority ^a	Vector Address or Offset ^b	Activation
Bus Fault	5	programmable ^c	0x0000.0014	Synchronous when precise and asynchronous when imprecise
Usage Fault	6	programmable ^c	0x0000.0018	Synchronous
-	7-10	-	-	Reserved
SVCALL	11	programmable ^c	0x0000.002C	Synchronous
Debug Monitor	12	programmable ^c	0x0000.0030	Synchronous
-	13	-	-	Reserved
PendSV	14	programmable ^c	0x0000.0038	Asynchronous
SysTick	15	programmable ^c	0x0000.003C	Asynchronous
Interrupts	16 and above	programmable ^d	0x0000.0040 and above	Asynchronous

a. 0 is the default priority for all the programmable priorities.

b. See “Vector Table” on page 128.

c. See **SYSPRI1** on page 187.d. See **PRIn** registers on page 169.**Table 2-9. Interrupts**

Vector Number	Interrupt Number (Bit in Interrupt Registers)	Vector Address or Offset	Description
0-15	-	0x0000.0000 - 0x0000.003C	Processor exceptions
16	0	0x0000.0040	GPIO Port A
17	1	0x0000.0044	GPIO Port B
18	2	0x0000.0048	GPIO Port C
19	3	0x0000.004C	GPIO Port D
20	4	0x0000.0050	GPIO Port E

129	113	-	Reserved

2.5.3 Exception Handlers

The processor handles exceptions using:

- **Interrupt Service Routines (ISRs).** Interrupts (IRQx) are the exceptions handled by ISRs.
- **Fault Handlers.** Hard fault, memory management fault, usage fault, and bus fault are fault exceptions handled by the fault handlers.
- **System Handlers.** NMI, PendSV, SVCALL, SysTick, and the fault exceptions are all system exceptions that are handled by system handlers.

2.5.4 Vector Table

The vector table contains the reset value of the stack pointer and the start addresses, also called exception vectors, for all exception handlers. The vector table is constructed using the vector address or offset shown in Table 2-8 on page 124. Figure 2-6 on page 129 shows the order of the exception vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is Thumb code

Figure 2-6. Vector Table

Exception number (N+16)	IRQ number (N)	Offset 0x040 + 0x(N*4)	Vector
.	.	0x004C	.
18	2	0x0048	IRQ N
17	1	0x0044	IRQ2
16	0	0x0040	IRQ1
15	-1	0x003C	IRQ0
14	-2	0x0038	Systick
13			PendSV
12			Reserved
11	-5	0x002C	Reserved for Debug
10			SVCall
9			Reserved
8			Reserved
7			
6	-10	0x0018	Usage fault
5	-11	0x0014	Bus fault
4	-12	0x0010	Memory management fault
3	-13	0x000C	Hard fault
2	-14	0x0008	NMI
1		0x0004	Reset
0		0x0000	Initial SP value

On system reset, the vector table is fixed at address 0x0000.0000. Privileged software can write to the **Vector Table Offset (VTABLE)** register to relocate the vector table start address to a different memory location, in the range 0x0000.0400 to 0x3FFF.FC00 (see “Vector Table” on page 128). Note that when configuring the **VTABLE** register, the offset must be aligned on a 1024-byte boundary.

2.5.5 Exception Priorities

As Table 2-8 on page 124 shows, all exceptions have an associated priority, with a lower priority value indicating a higher priority and configurable priorities for all exceptions except Reset, Hard fault, and NMI. If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities, see page 187 and page 169.

Note: Configurable priority values for the Tiva™ C Series implementation are in the range 0-7. This means that the Reset, Hard fault, and NMI exceptions, with fixed negative priority values, always have higher priority than any other exception.

For example, assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

2.5.6 Interrupt Priority Grouping

To increase priority control in systems with interrupts, the NVIC supports priority grouping. This grouping divides each interrupt priority register entry into two fields:

- An upper field that defines the group priority
- A lower field that defines a subpriority within the group

Only the group priority determines preemption of interrupt exceptions. When the processor is executing an interrupt exception handler, another interrupt with the same group priority as the interrupt being handled does not preempt the handler.

If multiple pending interrupts have the same group priority, the subpriority field determines the order in which they are processed. If multiple pending interrupts have the same group priority and subpriority, the interrupt with the lowest IRQ number is processed first.

For information about splitting the interrupt priority fields into group priority and subpriority, see page 181.

2.5.7 Exception Entry and Return

Descriptions of exception handling use the following terms:

- **Preemption.** When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled. See “Interrupt Priority Grouping” on page 130 for more information about preemption by an interrupt. When one exception preempts another, the exceptions are called nested exceptions. See “Exception Entry” on page 131 for more information.
- **Return.** Return occurs when the exception handler is completed, and there is no pending exception with sufficient priority to be serviced and the completed exception handler was not handling a late-arriving exception. The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See “Exception Return” on page 132 for more information.
- **Tail-Chaining.** This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.
- **Late-Arriving.** This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late arrival because the state saved is the same for both exceptions. Therefore, the state saving continues uninterrupted. The processor can accept a late arriving exception until the first instruction of the exception handler of the original exception enters the execute stage of the processor. On

return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.

2.5.7.1 Exception Entry

Exception entry occurs when there is a pending exception with sufficient priority and either the processor is in Thread mode or the new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception.

When one exception preempts another, the exceptions are nested.

Sufficient priority means the exception has more priority than any limits set by the mask registers (see **PRIMASK** on page 105, **FAULTMASK** on page 106, and **BASEPRI** on page 107). An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred to as *stacking* and the structure of eight data words is referred to as *stack frame*.

When using floating-point routines, the Cortex-M4F processor automatically stacks the architected floating-point state on exception entry. Figure 2-7 on page 132 shows the Cortex-M4F stack frame layout when floating-point state is preserved on the stack as the result of an interrupt or an exception.

Note: Where stack space for floating-point state is not allocated, the stack frame is the same as that of ARMv7-M implementations without an FPU. Figure 2-7 on page 132 shows this stack frame also.

Figure 2-7. Exception Stack Frame

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame.

The stack frame includes the return address, which is the address of the next instruction in the interrupted program. This value is restored to the **PC** at exception return so that the interrupted program resumes.

In parallel with the stacking operation, the processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an EXC_RETURN value to the **LR**, indicating which stack pointer corresponds to the stack frame and what operation mode the processor was in before the entry occurred.

If no higher-priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

If another higher-priority exception occurs during exception entry, known as late arrival, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception.

2.5.7.2 Exception Return

Exception return occurs when the processor is in Handler mode and executes one of the following instructions to load the EXC_RETURN value into the **PC**:

- An LDM or POP instruction that loads the **PC**
- A BX instruction using any register
- An LDR instruction with the **PC** as the destination

EXC_RETURN is the value loaded into the **LR** on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. The lowest five bits of this value provide information on the return stack and processor mode. Table 2-10 on page 133 shows the EXC_RETURN values with a description of the exception return behavior.

EXC_RETURN bits 31:5 are all set. When this value is loaded into the **PC**, it indicates to the processor that the exception is complete, and the processor initiates the appropriate exception return sequence.

Table 2-10. Exception Return Behavior

EXC_RETURN[31:0]	Description
0xFFFF.FFE0	Reserved
0xFFFF.FFE1	Return to Handler mode. Exception return uses floating-point state from MSP . Execution uses MSP after return.
0xFFFF.FFE2 - 0xFFFF.FFE8	Reserved
0xFFFF.FFE9	Return to Thread mode. Exception return uses floating-point state from MSP . Execution uses MSP after return.
0xFFFF.FFEA - 0xFFFF.FFEC	Reserved
0xFFFF.FFED	Return to Thread mode. Exception return uses floating-point state from PSP . Execution uses PSP after return.
0xFFFF.FFEE - 0xFFFF.FFF0	Reserved
0xFFFF.FFF1	Return to Handler mode. Exception return uses non-floating-point state from MSP . Execution uses MSP after return.
0xFFFF.FFF2 - 0xFFFF.FFF8	Reserved
0xFFFF.FFF9	Return to Thread mode. Exception return uses non-floating-point state from MSP . Execution uses MSP after return.
0xFFFF.FFFA - 0xFFFF.FFFC	Reserved
0xFFFF.FFFD	Return to Thread mode. Exception return uses non-floating-point state from PSP . Execution uses PSP after return.
0xFFFF.FFFE - 0xFFFF.FFFF	Reserved

2.6 Fault Handling

Faults are a subset of the exceptions (see “Exception Model” on page 122). The following conditions generate a fault:

- A bus error on an instruction fetch or vector table load or a data access.

- An internally detected error such as an undefined instruction or an attempt to change state with a BX instruction.
- Attempting to execute an instruction from a memory region marked as Non-Executable (XN).
- An MPU fault because of a privilege violation or an attempt to access an unmanaged region.

2.6.1 Fault Types

Table 2-11 on page 134 shows the types of fault, the handler used for the fault, the corresponding fault status register, and the register bit that indicates the fault has occurred. See page 194 for more information about the fault status registers.

Table 2-11. Faults

Fault	Handler	Fault Status Register	Bit Name
Bus error on a vector read	Hard fault	Hard Fault Status (HFAULTSTAT)	VECT
Fault escalated to a hard fault	Hard fault	Hard Fault Status (HFAULTSTAT)	FORCED
MPU or default memory mismatch on instruction access	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	IERR ^a
MPU or default memory mismatch on data access	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	DERR
MPU or default memory mismatch on exception stacking	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	MSTKE
MPU or default memory mismatch on exception unstacking	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	MUSTKE
MPU or default memory mismatch during lazy floating-point state preservation	Memory management fault	Memory Management Fault Status (MFAULTSTAT)	MLSPERR
Bus error during exception stacking	Bus fault	Bus Fault Status (BFAULTSTAT)	BSTKE
Bus error during exception unstacking	Bus fault	Bus Fault Status (BFAULTSTAT)	BUSTKE
Bus error during instruction prefetch	Bus fault	Bus Fault Status (BFAULTSTAT)	IBUS
Bus error during lazy floating-point state preservation	Bus fault	Bus Fault Status (BFAULTSTAT)	BLSPE
Precise data bus error	Bus fault	Bus Fault Status (BFAULTSTAT)	PRECISE
Imprecise data bus error	Bus fault	Bus Fault Status (BFAULTSTAT)	IMPRE
Attempt to access a coprocessor	Usage fault	Usage Fault Status (UFAULTSTAT)	NOCP
Undefined instruction	Usage fault	Usage Fault Status (UFAULTSTAT)	UNDEF
Attempt to enter an invalid instruction set state ^b	Usage fault	Usage Fault Status (UFAULTSTAT)	INVSTAT
Invalid EXC_RETURN value	Usage fault	Usage Fault Status (UFAULTSTAT)	INVPC
Illegal unaligned load or store	Usage fault	Usage Fault Status (UFAULTSTAT)	UNALIGN
Divide by 0	Usage fault	Usage Fault Status (UFAULTSTAT)	DIV0

a. Occurs on an access to an XN region even if the MPU is disabled.

b. Attempting to use an instruction set other than the Thumb instruction set, or returning to a non load-store-multiply instruction with ICI continuation.

2.6.2 Fault Escalation and Hard Faults

All fault exceptions except for hard fault have configurable exception priority (see **SYSPRI1** on page 187). Software can disable execution of the handlers for these faults (see **SYSHNDCTRL** on page 190).

Usually, the exception priority, together with the values of the exception mask registers, determines whether the processor enters the fault handler, and whether a fault handler can preempt another fault handler as described in “Exception Model” on page 122.

In some situations, a fault with configurable priority is treated as a hard fault. This process is called priority escalation, and the fault is described as *escalated to hard fault*. Escalation to hard fault occurs when:

- A fault handler causes the same kind of fault as the one it is servicing. This escalation to hard fault occurs because a fault handler cannot preempt itself because it must have the same priority as the current priority level.
- A fault handler causes a fault with the same or lower priority as the fault it is servicing. This situation happens because the handler for the new fault cannot preempt the currently executing fault handler.
- An exception handler causes a fault for which the priority is the same as or lower than the currently executing exception.
- A fault occurs and the handler for that fault is not enabled.

If a bus fault occurs during a stack push when entering a bus fault handler, the bus fault does not escalate to a hard fault. Thus if a corrupted stack causes a fault, the fault handler executes even though the stack push for the handler failed. The fault handler operates but the stack contents are corrupted.

Note: Only Reset and NMI can preempt the fixed priority hard fault. A hard fault can preempt any exception other than Reset, NMI, or another hard fault.

2.6.3 Fault Status Registers and Fault Address Registers

The fault status registers indicate the cause of a fault. For bus faults and memory management faults, the fault address register indicates the address accessed by the operation that caused the fault, as shown in Table 2-12 on page 135.

Table 2-12. Fault Status and Fault Address Registers

Handler	Status Register Name	Address Register Name	Register Description
Hard fault	Hard Fault Status (HFAULTSTAT)	-	page 200
Memory management fault	Memory Management Fault Status (MFAULTSTAT)	Memory Management Fault Address (MMADDR)	page 194 page 201
Bus fault	Bus Fault Status (BFAULTSTAT)	Bus Fault Address (FAULTADDR)	page 194 page 202
Usage fault	Usage Fault Status (UFAULTSTAT)	-	page 194

2.6.4 Lockup

The processor enters a lockup state if a hard fault occurs when executing the NMI or hard fault handlers. When the processor is in the lockup state, it does not execute any instructions. The processor remains in lockup state until it is reset, an NMI occurs, or it is halted by a debugger.

Note: If the lockup state occurs from the NMI handler, a subsequent NMI does not cause the processor to leave the lockup state.

2.7 Power Management

The Cortex-M4F processor sleep modes reduce power consumption:

- Sleep mode stops the processor clock.
- Deep-sleep mode stops the system clock and switches off the PLL and Flash memory.

The SLEEPDEEP bit of the **System Control (SYSCTRL)** register selects which sleep mode is used (see page 183). For more information about the behavior of the sleep modes, see “System Control” on page 250.

This section describes the mechanisms for entering sleep mode and the conditions for waking up from sleep mode, both of which apply to Sleep mode and Deep-sleep mode.

2.7.1 Entering Sleep Modes

This section describes the mechanisms software can use to put the processor into one of the sleep modes.

The system can generate spurious wake-up events, for example a debug operation wakes up the processor. Therefore, software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back to sleep mode.

2.7.1.1 Wait for Interrupt

The wait for interrupt instruction, `WFI`, causes immediate entry to sleep mode unless the wake-up condition is true (see “Wake Up from WFI or Sleep-on-Exit” on page 137). When the processor executes a `WFI` instruction, it stops executing instructions and enters sleep mode. See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (*literature number ARM DUI 0553A*) for more information.

2.7.1.2 Wait for Event

The wait for event instruction, `WFE`, causes entry to sleep mode conditional on the value of a one-bit event register. When the processor executes a `WFE` instruction, it checks the event register. If the register is 0, the processor stops executing instructions and enters sleep mode. If the register is 1, the processor clears the register and continues executing instructions without entering sleep mode.

If the event register is 1, the processor must not enter sleep mode on execution of a `WFE` instruction. Typically, this situation occurs if an `SEV` instruction has been executed. Software cannot access this register directly.

See the Cortex™-M4 instruction set chapter in the *ARM® Cortex™-M4 Devices Generic User Guide* (*literature number ARM DUI 0553A*) for more information.

2.7.1.3 Sleep-on-Exit

If the SLEEP EXIT bit of the **SYSCTRL** register is set, when the processor completes the execution of all exception handlers, it returns to Thread mode and immediately enters sleep mode. This mechanism can be used in applications that only require the processor to run when an exception occurs.

2.7.2 Wake Up from Sleep Mode

The conditions for the processor to wake up depend on the mechanism that caused it to enter sleep mode.

2.7.2.1 Wake Up from WFI or Sleep-on-Exit

Normally, the processor wakes up only when the NVIC detects an exception with sufficient priority to cause exception entry. Some embedded systems might have to execute system restore tasks after the processor wakes up and before executing an interrupt handler. Entry to the interrupt handler can be delayed by setting the PRIMASK bit and clearing the FAULTMASK bit. If an interrupt arrives that is enabled and has a higher priority than current exception priority, the processor wakes up but does not execute the interrupt handler until the processor clears PRIMASK. For more information about **PRIMASK** and **FAULTMASK**, see page 105 and page 106.

2.7.2.2 Wake Up from WFE

The processor wakes up if it detects an exception with sufficient priority to cause exception entry.

In addition, if the SEVONPEND bit in the **SYSCTRL** register is set, any new pending interrupt triggers an event and wakes up the processor, even if the interrupt is disabled or has insufficient priority to cause exception entry. For more information about **SYSCTRL**, see page 183.

2.8 Instruction Set Summary

The processor implements a version of the Thumb instruction set. Table 2-13 on page 137 lists the supported instructions.

Note: In Table 2-13 on page 137:

- Angle brackets, <>, enclose alternative forms of the operand
- Braces, {}, enclose optional operands
- The Operands column is not exhaustive
- Op2 is a flexible second operand that can be either a register or a constant
- Most instructions can use an optional condition code suffix

For more information on the instructions and operands, see the instruction descriptions in the *ARM® Cortex™-M4 Technical Reference Manual*.

Table 2-13. Cortex-M4F Instruction Summary

Mnemonic	Operands	Brief Description	Flags
ADC, ADCS	{Rd, } Rn, Op2	Add with carry	N,Z,C,V
ADD, ADDS	{Rd, } Rn, Op2	Add	N,Z,C,V
ADD, ADDW	{Rd, } Rn , #imm12	Add	-
ADR	Rd, label	Load PC-relative address	-

3 Cortex-M4 Peripherals

This chapter provides information on the Tiva™ C Series implementation of the Cortex-M4 processor peripherals, including:

- SysTick (see page 145)
Provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism.
- Nested Vectored Interrupt Controller (NVIC) (see page 146)
 - Facilitates low-latency exception and interrupt handling
 - Controls power management
 - Implements system control registers
- System Control Block (SCB) (see page 147)
Provides system implementation information and system control, including configuration, control, and reporting of system exceptions.
- Memory Protection Unit (MPU) (see page 147)
Supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.
- Floating-Point Unit (FPU) (see page 152)
Fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

Table 3-1 on page 144 shows the address map of the Private Peripheral Bus (PPB). Some peripheral register regions are split into two address regions, as indicated by two addresses listed.

Table 3-1. Core Peripheral Register Regions

Address	Core Peripheral	Description (see page ...)
0xE000.E010-0xE000.E01F	System Timer	145
0xE000.E100-0xE000.E4EF	Nested Vectored Interrupt Controller	146
0xE000.EF00-0xE000.EF03		
0xE000.E008-0xE000.E00F	System Control Block	147
0xE000.ED00-0xE000.ED3F		
0xE000.ED90-0xE000.EDB8	Memory Protection Unit	147
0xE000.EF30-0xE000.EF44	Floating Point Unit	152

3.1 Functional Description

This chapter provides information on the Tiva™ C Series implementation of the Cortex-M4 processor peripherals: SysTick, NVIC, SCB, MPU, FPU.

3.1.1 System Timer (SysTick)

Cortex-M4 includes an integrated system timer, SysTick, which provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example as:

- An RTOS tick timer that fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter used to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNT bit in the **STCTRL** control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

The timer consists of three registers:

- **SysTick Control and Status (STCTRL)**: A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- **SysTick Reload Value (STRELOAD)**: The reload value for the counter, used to provide the counter's wrap value.
- **SysTick Current Value (STCURRENT)**: The current value of the counter.

When enabled, the timer counts down on each clock from the reload value to zero, reloads (wraps) to the value in the **STRELOAD** register on the next clock edge, then decrements on subsequent clocks. Clearing the **STRELOAD** register disables the counter on the next wrap. When the counter reaches zero, the COUNT status bit is set. The COUNT bit clears on reads.

Writing to the **STCURRENT** register clears the register and the COUNT status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

The SysTick counter runs on the system clock. If this clock signal is stopped for low power mode, the SysTick counter stops. Ensure software uses aligned word accesses to access the SysTick registers.

The SysTick counter reload and current value are undefined at reset; the correct initialization sequence for the SysTick counter is:

1. Program the value in the **STRELOAD** register.
2. Clear the **STCURRENT** register by writing to it with any value.
3. Configure the **STCTRL** register for the required operation.

Note: When the processor is halted for debugging, the counter does not decrement.

3.1.2 Nested Vectored Interrupt Controller (NVIC)

This section describes the Nested Vectored Interrupt Controller (NVIC) and the registers it uses. The NVIC supports:

- 109 interrupts.
- A programmable priority level of 0-7 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Low-latency exception and interrupt handling.
- Level and pulse detection of interrupt signals.
- Dynamic reprioritization of interrupts.
- Grouping of priority values into group priority and subpriority fields.
- Interrupt tail-chaining.
- An external Non-maskable interrupt (NMI).

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead, providing low latency exception handling.

3.1.2.1 Level-Sensitive and Pulse Interrupts

The processor supports both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt (see “Hardware and Software Control of Interrupts” on page 146 for more information). For a level-sensitive interrupt, if the signal is not deasserted before the processor returns from the ISR, the interrupt becomes pending again, and the processor must execute its ISR again. As a result, the peripheral can hold the interrupt signal asserted until it no longer needs servicing.

3.1.2.2 Hardware and Software Control of Interrupts

The Cortex-M4 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- The NVIC detects that the interrupt signal is High and the interrupt is not active.
- The NVIC detects a rising edge on the interrupt signal.
- Software writes to the corresponding interrupt set-pending register bit, or to the **Software Trigger Interrupt (SWTRIG)** register to make a Software-Generated Interrupt pending. See the `INT` bit in the **PEND0** register on page 166 or **SWTRIG** on page 173.

A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt, changing the state of the interrupt from pending to active. Then:
 - For a level-sensitive interrupt, when the processor returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
 - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR.

If the interrupt signal is not pulsed while the processor is in the ISR, when the processor returns from the ISR the state of the interrupt changes to inactive.
- Software writes to the corresponding interrupt clear-pending register bit
 - For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
 - For a pulse interrupt, the state of the interrupt changes to inactive, if the state was pending or to active, if the state was active and pending.

3.1.3 System Control Block (SCB)

The System Control Block (SCB) provides system implementation information and system control, including configuration, control, and reporting of the system exceptions.

3.1.4 Memory Protection Unit (MPU)

This section describes the Memory protection unit (MPU). The MPU divides the memory map into a number of regions and defines the location, size, access permissions, and memory attributes of each region. The MPU supports independent attribute settings for each region, overlapping regions, and export of memory attributes to the system.

The memory attributes affect the behavior of memory accesses to the region. The Cortex-M4 MPU defines eight separate memory regions, 0-7, and a background region.

When memory regions overlap, a memory access is affected by the attributes of the region with the highest number. For example, the attributes for region 7 take precedence over the attributes of any region that overlaps region 7.

The background region has the same memory access attributes as the default memory map, but is accessible from privileged software only.

The Cortex-M4 MPU memory map is unified, meaning that instruction accesses and data accesses have the same region settings.

If a program accesses a memory location that is prohibited by the MPU, the processor generates a memory management fault, causing a fault exception and possibly causing termination of the process in an OS environment. In an OS environment, the kernel can update the MPU region setting dynamically based on the process to be executed. Typically, an embedded OS uses the MPU for memory protection.

Configuration of MPU regions is based on memory types (see “Memory Regions, Types and Attributes” on page 116 for more information).

Table 3-2 on page 148 shows the possible MPU region attributes. See the section called “MPU Configuration for a Tiva™ C Series Microcontroller” on page 152 for guidelines for programming a microcontroller implementation.

Table 3-2. Memory Attributes Summary

Memory Type	Description
Strongly Ordered	All accesses to Strongly Ordered memory occur in program order.
Device	Memory-mapped peripherals
Normal	Normal memory

To avoid unexpected behavior, disable the interrupts before updating the attributes of a region that the interrupt handlers might access.

Ensure software uses aligned accesses of the correct size to access MPU registers:

- Except for the **MPU Region Attribute and Size (MPUATTR)** register, all MPU registers must be accessed with aligned word accesses.
- The **MPUATTR** register can be accessed with byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to MPU registers.

When setting up the MPU, and if the MPU has previously been programmed, disable unused regions to prevent any previous region settings from affecting the new MPU setup.

3.1.4.1 Updating an MPU Region

To update the attributes for an MPU region, the **MPU Region Number (MPUNUMBER)**, **MPU Region Base Address (MPUBASE)** and **MPUATTR** registers must be updated. Each register can be programmed separately or with a multiple-word write to program all of these registers. You can use the **MPUBASEx** and **MPUATTRx** aliases to program up to four regions simultaneously using an STM instruction.

Updating an MPU Region Using Separate Words

This example simple code configures one region:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER           ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]           ; Region Number
STR R4, [R0, #0x4]           ; Region Base Address
STRH R2, [R0, #0x8]          ; Region Size and Enable
STRH R3, [R0, #0xA]          ; Region Attribute
```

Disable a region before writing new region settings to the MPU if you have previously enabled the region being changed. For example:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPUNUMBER           ; 0xE000ED98, MPU region number register
```

```

STR R1, [R0, #0x0]           ; Region Number
BIC R2, R2, #1               ; Disable
STRH R2, [R0, #0x8]          ; Region Size and Enable
STR R4, [R0, #0x4]           ; Region Base Address
STRH R3, [R0, #0xA]          ; Region Attribute
ORR R2, #1                  ; Enable
STRH R2, [R0, #0x8]          ; Region Size and Enable

```

Software must use memory barrier instructions:

- Before MPU setup, if there might be outstanding memory transfers, such as buffered writes, that might be affected by the change in MPU settings.
- After MPU setup, if it includes memory transfers that must use the new MPU settings.

However, memory barrier instructions are not required if the MPU setup process starts by entering an exception handler, or is followed by an exception return, because the exception entry and exception return mechanism cause memory barrier behavior.

Software does not need any memory barrier instructions during MPU setup, because it accesses the MPU through the Private Peripheral Bus (PPB), which is a Strongly Ordered memory region.

For example, if all of the memory access behavior is intended to take effect immediately after the programming sequence, then a `DSB` instruction and an `ISB` instruction should be used. A `DSB` is required after changing MPU settings, such as at the end of context switch. An `ISB` is required if the code that programs the MPU region or regions is entered using a branch or call. If the programming sequence is entered using a return from exception, or by taking an exception, then an `ISB` is not required.

Updating an MPU Region Using Multi-Word Writes

The MPU can be programmed directly using multi-word writes, depending how the information is divided. Consider the following reprogramming:

```

; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0] ; Region Number
STR R2, [R0, #0x4] ; Region Base Address
STR R3, [R0, #0x8] ; Region Attribute, Size and Enable

```

An `STM` instruction can be used to optimize this:

```

; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPUNUMBER ; 0xE000ED98, MPU region number register
STM R0, {R1-R3}     ; Region number, address, attribute, size and enable

```

This operation can be done in two words for prepended information, meaning that the **MPU Region Base Address (MPUBASE)** register (see page 207) contains the required region number and has the VALID bit set. This method can be used when the data is statically packed, for example in a boot loader:

```

; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPUBASE      ; 0xE000ED9C, MPU Region Base register
STR R1, [R0, #0x0]    ; Region base address and region number combined
                      ; with VALID (bit 4) set
STR R2, [R0, #0x4]    ; Region Attribute, Size and Enable

```

Subregions

Regions of 256 bytes or more are divided into eight equal-sized subregions. Set the corresponding bit in the SRD field of the **MPU Region Attribute and Size (MPUATTR)** register (see page 209) to disable a subregion. The least-significant bit of the SRD field controls the first subregion, and the most-significant bit controls the last subregion. Disabling a subregion means another region overlapping the disabled range matches instead. If no other enabled region overlaps the disabled subregion, the MPU issues a fault.

Regions of 32, 64, and 128 bytes do not support subregions. With regions of these sizes, the SRD field must be configured to 0x00, otherwise the MPU behavior is unpredictable.

Example of SRD Use

Two regions with the same base address overlap. Region one is 128 KB, and region two is 512 KB. To ensure the attributes from region one apply to the first 128 KB region, configure the SRD field for region two to 0x03 to disable the first two subregions, as Figure 3-1 on page 150 shows.

Figure 3-1. SRD Use Example

3.1.4.2 MPU Access Permission Attributes

The access permission bits, TEX, S, C, B, AP, and XN of the **MPUATTR** register, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

Table 3-3 on page 150 shows the encodings for the TEX, C, B, and S access permission bits. All encodings are shown for completeness, however the current implementation of the Cortex-M4 does not support the concept of cacheability or shareability. Refer to the section called “MPU Configuration for a Tiva™ C Series Microcontroller” on page 152 for information on programming the MPU for TM4C129XKCZAD implementations.

Table 3-3. TEX, S, C, and B Bit Field Encoding

TEX	S	C	B	Memory Type	Shareability	Other Attributes
000b	x ^a	0	0	Strongly Ordered	Shareable	-
000	x ^a	0	1	Device	Shareable	-

Table 3-3. TEX, S, C, and B Bit Field Encoding (continued)

TEX	S	C	B	Memory Type	Shareability	Other Attributes
000	0	1	0	Normal	Not shareable	
000	1	1	0	Normal	Shareable	Outer and inner write-through. No write allocate.
000	0	1	1	Normal	Not shareable	
000	1	1	1	Normal	Shareable	
001	0	0	0	Normal	Not shareable	Outer and inner non-cacheable.
001	1	0	0	Normal	Shareable	
001	x ^a	0	1	Reserved encoding	-	-
001	x ^a	1	0	Reserved encoding	-	-
001	0	1	1	Normal	Not shareable	Outer and inner write-back. Write and read allocate.
001	1	1	1	Normal	Shareable	
010	x ^a	0	0	Device	Not shareable	Nonshared Device.
010	x ^a	0	1	Reserved encoding	-	-
010	x ^a	1	x ^a	Reserved encoding	-	-
1BB	0	A	A	Normal	Not shareable	Cached memory (BB = outer policy, AA = inner policy).
1BB	1	A	A	Normal	Shareable	See Table 3-4 for the encoding of the AA and BB bits.

a. The MPU ignores the value of this bit.

Table 3-4 on page 151 shows the cache policy for memory attribute encodings with a **TEX** value in the range of 0x4-0x7.

Table 3-4. Cache Policy for Memory Attribute Encoding

Encoding, AA or BB	Corresponding Cache Policy
00	Non-cacheable
01	Write back, write and read allocate
10	Write through, no write allocate
11	Write back, no write allocate

Table 3-5 on page 151 shows the **AP** encodings in the **MPUATTR** register that define the access permissions for privileged and unprivileged software.

Table 3-5. AP Bit Field Encoding

AP Bit Field	Privileged Permissions	Unprivileged Permissions	Description
000	No access	No access	All accesses generate a permission fault.
001	RW	No access	Access from privileged software only.
010	RW	RO	Writes by unprivileged software generate a permission fault.
011	RW	RW	Full access.
100	Unpredictable	Unpredictable	Reserved.
101	RO	No access	Reads by privileged software only.

Table 3-5. AP Bit Field Encoding (continued)

AP Bit Field	Privileged Permissions	Unprivileged Permissions	Description
110	RO	RO	Read-only, by privileged or unprivileged software.
111	RO	RO	Read-only, by privileged or unprivileged software.

MPU Configuration for a Tiva™ C Series Microcontroller

Tiva™ C Series microcontrollers have only a single processor and no caches. As a result, the MPU should be programmed as shown in Table 3-6 on page 152.

Table 3-6. Memory Region Attributes for Tiva™ C Series Microcontrollers

Memory Region	TEX	S	C	B	Memory Type and Attributes
Flash memory	000b	0	1	0	Normal memory, non-shareable, write-through
Internal SRAM	000b	1	1	0	Normal memory, shareable, write-through
External SRAM	000b	1	1	1	Normal memory, shareable, write-back, write-allocate
Peripherals	000b	1	0	1	Device memory, shareable

In current Tiva™ C Series microcontroller implementations, the shareability and cache policy attributes do not affect the system behavior. However, using these settings for the MPU regions can make the application code more portable. The values given are for typical situations.

3.1.4.3 MPU Mismatch

When an access violates the MPU permissions, the processor generates a memory management fault (see “Exceptions and Interrupts” on page 112 for more information). The **MFAULTSTAT** register indicates the cause of the fault. See page 194 for more information.

3.1.5 Floating-Point Unit (FPU)

This section describes the Floating-Point Unit (FPU) and the registers it uses. The FPU provides:

- 32-bit instructions for single-precision (C float) data-processing operations
- Combined multiply and accumulate instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication with optional accumulate, division, and square-root
- Hardware support for denormals and all IEEE rounding modes
- 32 dedicated 32-bit single-precision registers, also addressable as 16 double-word registers
- Decoupled three stage pipeline

The Cortex-M4F FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions. The FPU provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic, referred to as the IEEE 754 standard. The FPU's single-precision extension registers can also be accessed as 16 doubleword registers for load, store, and move operations.

3.1.5.1 FPU Views of the Register Bank

The FPU provides an extension register file containing 32 single-precision registers. These can be viewed as:

- Sixteen 64-bit doubleword registers, D0-D15
- Thirty-two 32-bit single-word registers, S0-S31
- A combination of registers from the above views

Figure 3-2. FPU Register Bank

The mapping between the registers is as follows:

- S<2n> maps to the least significant half of D<n>
- S<2n+1> maps to the most significant half of D<n>

For example, you can access the least significant half of the value in D6 by accessing S12, and the most significant half of the elements by accessing S13.

3.1.5.2 Modes of Operation

The FPU provides three modes of operation to accommodate a variety of applications.

Full-Compliance mode. In Full-Compliance mode, the FPU processes all operations according to the IEEE 754 standard in hardware.

Flush-to-Zero mode. Setting the `FZ` bit of the **Floating-Point Status and Control (FPSC)** register enables Flush-to-Zero mode. In this mode, the FPU treats all subnormal input operands of arithmetic CDP operations as zeros in the operation. Exceptions that result from a zero operand are signalled appropriately. VABS, VNEG, and VMOV are not considered arithmetic CDP operations and are not affected by Flush-to-Zero mode. A result that is tiny, as described in the IEEE 754 standard, where the destination precision is smaller in magnitude than the minimum normal value before rounding, is replaced with a zero. The `IDC` bit in **FPSC** indicates when an input flush occurs. The `UFC` bit in **FPSC** indicates when a result flush occurs.

Default NaN mode. Setting the `DN` bit in the **FPSC** register enables default NaN mode. In this mode, the result of any arithmetic data processing operation that involves an input NaN, or that generates a NaN result, returns the default NaN. Propagation of the fraction bits is maintained only by VABS,

VNEG, and VMOV operations. All other CDP operations ignore any information in the fraction bits of an input NaN.

3.1.5.3 Compliance with the IEEE 754 standard

When Default NaN (DN) and Flush-to-Zero (FZ) modes are disabled, FPv4 functionality is compliant with the IEEE 754 standard in hardware. No support code is required to achieve this compliance.

3.1.5.4 Complete Implementation of the IEEE 754 standard

The Cortex-M4F floating point instruction set does not support all operations defined in the IEEE 754-2008 standard. Unsupported operations include, but are not limited to the following:

- Remainder
- Round floating-point number to integer-valued floating-point number
- Binary-to-decimal conversions
- Decimal-to-binary conversions
- Direct comparison of single-precision and double-precision values

The Cortex-M4 FPU supports fused MAC operations as described in the IEEE standard. For complete implementation of the IEEE 754-2008 standard, floating-point functionality must be augmented with library functions.

3.1.5.5 IEEE 754 standard implementation choices

Nan handling

All single-precision values with the maximum exponent field value and a nonzero fraction field are valid NaNs. A most-significant fraction bit of zero indicates a Signaling NaN (SNaN). A one indicates a Quiet NaN (QNaN). Two NaN values are treated as different NaNs if they differ in any bit. The below table shows the default NaN values.

Sign	Fraction	Fraction
0	0xFF	bit [22] = 1, bits [21:0] are all zeros

Processing of input NaNs for ARM floating-point functionality and libraries is defined as follows:

- In full-compliance mode, NaNs are handled as described in the ARM Architecture Reference Manual. The hardware processes the NaNs directly for arithmetic CDP instructions. For data transfer operations, NaNs are transferred without raising the Invalid Operation exception. For the non-arithmetic CDP instructions, VABS, VNEG, and VMOV, NaNs are copied, with a change of sign if specified in the instructions, without causing the Invalid Operation exception.
- In default NaN mode, arithmetic CDP instructions involving NaN operands return the default NaN regardless of the fractions of any NaN operands. SNaNs in an arithmetic CDP operation set the IOC flag, FPSCR[0]. NaN handling by data transfer and non-arithmetic CDP instructions is the same as in full-compliance mode.

Table 3-7. QNaN and SNaN Handling

Instruction Type	Default NaN Mode	With QNaN Operand	With SNaN Operand
Arithmetic CDP	Off	The QNaN or one of the QNaN operands, if there is more than one, is returned according to the rules given in the ARM Architecture Reference Manual.	IOC ^a set. The SNaN is quieted and the result NaN is determined by the rules given in the ARM Architecture Reference Manual.
	On	Default NaN returns.	IOC ^a set. Default NaN returns.
Non-arithmetic CDP	Off/On	NaN passes to destination with sign changed as appropriate.	
FCMP(Z)	-	Unordered compare.	IOC set. Unordered compare.
FCMPE(Z)	-	IOC set. Unordered compare.	IOC set. Unordered compare.
Load/store	Off/On	All NaNs transferred.	

a. IOC is the Invalid Operation exception flag, FPSCR[0].

Comparisons

Comparison results modify the flags in the FPSCR. You can use the MVRS APSR_nzcv instruction (formerly FMSTAT) to transfer the current flags from the FPSCR to the APSR. See the ARM Architecture Reference Manual for mapping of IEEE 754-2008 standard predicates to ARM conditions. The flags used are chosen so that subsequent conditional execution of ARM instructions can test the predicates defined in the IEEE standard.

Underflow

The Cortex-M4F FPU uses the before rounding form of tininess and the inexact result form of loss of accuracy as described in the IEEE 754-2008 standard to generate Underflow exceptions.

In flush-to-zero mode, results that are tiny before rounding, as described in the IEEE standard, are flushed to a zero, and the UFC flag, FPSCR[3], is set. See the ARM Architecture Reference Manual for information on flush-to-zero mode.

When the FPU is not in flush-to-zero mode, operations are performed on subnormal operands. If the operation does not produce a tiny result, it returns the computed result, and the UFC flag, FPSCR[3], is not set. The IXC flag, FPSCR[4], is set if the operation is inexact. If the operation produces a tiny result, the result is a subnormal or zero value, and the UFC flag, FPSCR[3], is set if the result was also inexact.

3.1.5.6 Exceptions

The FPU sets the cumulative exception status flag in the FPSCR register as required for each instruction, in accordance with the FPv4 architecture. The FPU does not support user-mode traps. The exception enable bits in the FPSCR read-as-zero, and writes are ignored. The processor also has six output pins, FPIXC, FPUFC, FPOFC, FPDZC, FPIDC, and FPIOC, that each reflect the status of one of the cumulative exception flags. For a description of these outputs, see the *ARM Cortex-M4 Integration and Implementation Manual* (ARM D11 0239, available from ARM).

The processor can reduce the exception latency by using lazy stacking. See Auxiliary Control Register, ACTLR on page 4-5. This means that the processor reserves space on the stack for the FP state, but does not save that state information to the stack. See the ARMv7-M Architecture Reference Manual (available from ARM) for more information.

3.1.5.7 Enabling the FPU

The FPU is disabled from reset. You must enable it before you can use any floating-point instructions. The processor must be in privileged mode to read from and write to the **Coprocessor Access**

Control (CPAC) register. The below example code sequence enables the FPU in both privileged and user modes.

```
; CPACR is located at address 0xE000ED88
LDR.W R0, =0xE000ED88
; Read CPACR
LDR R1, [R0]
; Set bits 20-23 to enable CP10 and CP11 coprocessors
ORR R1, R1, #(0xF << 20)
; Write back the modified value to the CPACR
STR R1, [R0]; wait for store to complete
DSB
;reset pipeline now the FPU is enabled
ISB
```

3.2 Register Map

Table 3-8 on page 156 lists the Cortex-M4 Peripheral SysTick, NVIC, MPU, FPU and SCB registers. The offset listed is a hexadecimal increment to the register's address, relative to the Core Peripherals base address of 0xE000.E000.

Note: Register spaces that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Table 3-8. Peripherals Register Map

Offset	Name	Type	Reset	Description	See page
System Timer (SysTick) Registers					
0x010	STCTRL	RW	0x0000.0000	SysTick Control and Status Register	160
0x014	STRELOAD	RW	-	SysTick Reload Value Register	162

3.3 System Timer (SysTick) Register Descriptions

This section lists and describes the System Timer registers, in numerical order by address offset.

Register 1: SysTick Control and Status Register (STCTRL), offset 0x010

Note: This register can only be accessed from privileged mode.

The SysTick **STCTRL** register enables the SysTick features.

SysTick Control and Status Register (STCTRL)

Base 0xE000.E000
Offset 0x010
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:17	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
16	COUNT	RO	0	Count Flag <table border="1"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>The SysTick timer has not counted to 0 since the last time this bit was read.</td> </tr> <tr> <td>1</td> <td>The SysTick timer has counted to 0 since the last time this bit was read.</td> </tr> </table> This bit is cleared by a read of the register or if the STCURRENT register is written with any value. If read by the debugger using the DAP, this bit is cleared only if the MasterType bit in the AHB-AP Control Register is clear. Otherwise, the COUNT bit is not changed by the debugger read. See the <i>ARM® Debug Interface V5 Architecture Specification</i> for more information on MasterType .	Value	Description	0	The SysTick timer has not counted to 0 since the last time this bit was read.	1	The SysTick timer has counted to 0 since the last time this bit was read.
Value	Description									
0	The SysTick timer has not counted to 0 since the last time this bit was read.									
1	The SysTick timer has counted to 0 since the last time this bit was read.									
15:3	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
2	CLK_SRC	RW	0	Clock Source <table border="1"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>Precision internal oscillator (PIOSC) divided by 4</td> </tr> <tr> <td>1</td> <td>System clock</td> </tr> </table>	Value	Description	0	Precision internal oscillator (PIOSC) divided by 4	1	System clock
Value	Description									
0	Precision internal oscillator (PIOSC) divided by 4									
1	System clock

Software can use the COUNT bit to determine if the counter has ever reached 0.	1	An interrupt is generated to the NVIC when SysTick counts to 0.
Value	Description									
0	Interrupt generation is disabled. Software can use the COUNT bit to determine if the counter has ever reached 0.									
1	An interrupt is generated to the NVIC when SysTick counts to 0.									
0	ENABLE	RW	0	Enable						
				<table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The counter is disabled.</td></tr> <tr> <td>1</td><td>Enables SysTick to operate in a multi-shot way. That is, the counter loads the RELOAD value and begins counting down. On reaching 0, the COUNT bit is set and an interrupt is generated if enabled by INTEN. The counter then loads the RELOAD value again and begins counting.</td></tr> </tbody> </table>	Value	Description	0	The counter is disabled.	1	Enables SysTick to operate in a multi-shot way. That is, the counter loads the RELOAD value and begins counting down. On reaching 0, the COUNT bit is set and an interrupt is generated if enabled by INTEN. The counter then loads the RELOAD value again and begins counting.
Value	Description									
0	The counter is disabled.									
1	Enables SysTick to operate in a multi-shot way. That is, the counter loads the RELOAD value and begins counting down. On reaching 0, the COUNT bit is set and an interrupt is generated if enabled by INTEN. The counter then loads the RELOAD value again and begins counting.									

Register 2: SysTick Reload Value Register (STRELOAD), offset 0x014

Note: This register can only be accessed from privileged mode.

The **STRELOAD** register specifies the start value to load into the **SysTick Current Value (STCURRENT)** register when the counter reaches 0. The start value can be between 0x1 and 0x00FF.FFFF. A start value of 0 is possible but has no effect because the SysTick interrupt and the COUNT bit are activated when counting from 1 to 0.

SysTick can be configured as a multi-shot timer, repeated over and over, firing every N+1 clock pulses, where N is any value from 1 to 0x00FF.FFFF. For example, if a tick interrupt is required every 100 clock pulses, 99 must be written into the RELOAD field.

Note that in order to access this register correctly, the system clock must be faster than 8 MHz.

SysTick Reload Value Register (STRELOAD)

Base 0xE000.E000

Offset 0x014

23:0	RELOAD	RW	0x00.0000	Reload Value Value to load into the SysTick Current Value (STCURRENT) register when the counter reaches 0.

Register 3: SysTick Current Value Register (STCURRENT), offset 0x018

Note: This register can only be accessed from privileged mode.

The **STCURRENT** register contains the current value of the SysTick counter.

SysTick Current Value Register (STCURRENT)

Base 0xE000.E000

Offset 0x018

Type RWC, reset -

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	CURRENT	RWC	0x00.0000	<p>Current Value</p> <p>This field contains the current value at the time the register is accessed. No read-modify-write protection is provided, so change with care.</p> <p>This register is write-clear. Writing to it with any value clears the register. Clearing this register also clears the COUNT bit of the STCTRL register.</p>

3.4 NVIC Register Descriptions

This section lists and describes the NVIC registers, in numerical order by address offset.

The NVIC registers can only be fully accessed from privileged mode, but interrupts can be pended while in unprivileged mode by enabling the **Configuration and Control (CFGCTRL)** register. Any other unprivileged mode access causes a bus fault.

Ensure software uses correctly aligned register accesses. The processor does not support unaligned accesses to NVIC registers.

An interrupt can enter the pending state even if it is disabled.

Before programming the **VTABLE** register to relocate the vector table, ensure the vector table entries of the new vector table are set up for fault handlers, NMI, and all enabled exceptions such as interrupts. For more information, see page 180.

- Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100**
- Register 5: Interrupt 32-63 Set Enable (EN1), offset 0x104**
- Register 6: Interrupt 64-95 Set Enable (EN2), offset 0x108**
- Register 7: Interrupt 96-113 Set Enable (EN3), offset 0x10C**

Note: This register can only be accessed from privileged mode.

The **ENn** registers enable interrupts and show which interrupts are enabled. Bit 0 of **EN0** corresponds to Interrupt 0; bit 31 corresponds to Interrupt 31. Bit 0 of **EN1** corresponds to Interrupt 32; bit 31 corresponds to Interrupt 63. Bit 0 of **EN2** corresponds to Interrupt 64; bit 31 corresponds to Interrupt 95. Bit 0 of **EN3** corresponds to Interrupt 96; bit 17 corresponds to Interrupt 113.

See Table 2-9 on page 125 for interrupt assignments.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

Interrupt 0-31 Set Enable (EN0)

Base 0xE000.E000

Offset 0x100

Type RW, reset 0x0000.0000

																INT																
Type	RW

- Register 38: Interrupt 56-59 Priority (PRI14), offset 0x438**
- Register 39: Interrupt 60-63 Priority (PRI15), offset 0x43C**

Note: This register can only be accessed from privileged mode.

The **PRI_n** registers (see also page 171) provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

PRIn Register Bit Field	Interrupt
Bits 31:29	Interrupt [4n+3]
Bits 23:21	Interrupt [4n+2]
Bits 15:13	Interrupt [4n+1]
Bits 7:5	Interrupt [4n]

See Table 2-9 on page 125 for interrupt assignments.

Each priority level can be split into separate group priority and subpriority fields. The **PRIGROUP** field in the **Application Interrupt and Reset Control (APINT)** register (see page 181) indicates the position of the binary point that splits the priority and subpriority fields.

These registers can only be accessed from privileged mode.

23:21	INTC	RW	0x0	Interrupt Priority for Interrupt [4n+2] This field holds a priority value, 0-7, for the interrupt with the number [4n+2], where n is the number of the Interrupt Priority register (n=0 for PRI0 , and so on). The lower the value, the greater the priority of the corresponding interrupt.
20:16	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:13	INTB	RW	0x0	Interrupt Priority for Interrupt [4n+1] This field holds a priority value, 0-7, for the interrupt with the number [4n+1], where n is the number of the Interrupt Priority register (n=0 for PRI0 , and so on). The lower the value, the greater the priority of the corresponding interrupt.
12:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:5	INTA	RW	0x0	Interrupt Priority for Interrupt [4n] This field holds a priority value, 0-7, for the interrupt with the number [4n], where n is the number of the Interrupt Priority register (n=0 for PRI0 , and so on). The lower the value, the greater the priority of the corresponding interrupt.
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 53: Software Trigger Interrupt (SWTRIG), offset 0xF00

Note: Only privileged software can enable unprivileged access to the **SWTRIG** register.

Writing an interrupt number to the **SWTRIG** register generates a Software Generated Interrupt (SGI). See Table 2-9 on page 125 for interrupt assignments.

When the **MAINPEND** bit in the **Configuration and Control (CFGCTRL)** register (see page 185) is set, unprivileged software can access the **SWTRIG** register.

Software Trigger Interrupt (SWTRIG)

Base 0xE000.E000
Offset 0xF00
Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	INTID	WO	0x00	Interrupt ID This field holds the interrupt ID of the required SGI. For example, a value of 0x3 generates an interrupt on IRQ3.

3.5 System Control Block (SCB) Register Descriptions

This section lists and describes the System Control Block (SCB) registers, in numerical order by address offset. The SCB registers can only be accessed from privileged mode.

All registers must be accessed with aligned word accesses except for the **FAULTSTAT** and **SYSPRI1-SYSPRI3** registers, which can be accessed with byte or aligned halfword or word accesses. The processor does not support unaligned accesses to system control block registers.

Register 54: Auxiliary Control (ACTLR), offset 0x008

Note: This register can only be accessed from privileged mode.

The **ACTLR** register provides disable bits for **IT** folding, write buffer use for accesses to the default memory map, and interruption of multi-cycle instructions. By default, this register is set to provide optimum performance from the Cortex-M4 processor and does not normally require modification.

Auxiliary Control (ACTLR)

Base 0xE000.E000
Offset 0x008
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:10	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
9	DISOOFP	RW	0	Disable Out-Of-Order Floating Point Disables floating-point instructions completing out of order with respect to integer instructions.						
8	DISFPCA	RW	0	Disable CONTROL.FPCA Disable automatic update of the FPCA bit in the CONTROL register.						
Important: Two bits control when FPCA can be enabled: the ASPEN bit in the Floating-Point Context Control (FPCC) register and the DISFPCA bit in the Auxiliary Control (ACTLR) register.										
7:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
2	DISFOLD	RW	0	Disable IT Folding <table border="0" style="margin-left: 20px;"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>No effect.</td> </tr> <tr> <td>1</td> <td>Disables IT folding.</td> </tr> </table>	Value	Description	0	No effect.	1	Disables IT folding.
Value	Description									
0	No effect.									
1	Disables IT folding.									

In some situations, the processor can start executing the first instruction in an **IT** block while it is still executing the **IT** instruction. This behavior is called **IT folding**, and improves performance. However, **IT** folding can cause jitter in looping. If a task must avoid jitter, set the **DISFOLD** bit before executing the task, to disable **IT** folding.

Bit/Field	Name	Type	Reset	Description						
1	DISWBUF	RW	0	<p>Disable Write Buffer</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No effect.</td></tr> <tr> <td>1</td><td>Disables write buffer use during default memory map accesses. In this situation, all bus faults are precise bus faults but performance is decreased because any store to memory must complete before the processor can execute the next instruction.</td></tr> </tbody> </table> <p>Note: This bit only affects write buffers implemented in the Cortex-M4 processor.</p>	Value	Description	0	No effect.	1	Disables write buffer use during default memory map accesses. In this situation, all bus faults are precise bus faults but performance is decreased because any store to memory must complete before the processor can execute the next instruction.
Value	Description									
0	No effect.									
1	Disables write buffer use during default memory map accesses. In this situation, all bus faults are precise bus faults but performance is decreased because any store to memory must complete before the processor can execute the next instruction.									
0	DISMCYC	RW	0	<p>Disable Interrupts of Multiple Cycle Instructions</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No effect.</td></tr> <tr> <td>1</td><td>Disables interruption of load multiple and store multiple instructions. In this situation, the interrupt latency of the processor is increased because any LDM or STM must complete before the processor can stack the current state and enter the interrupt handler.</td></tr> </tbody> </table>	Value	Description	0	No effect.	1	Disables interruption of load multiple and store multiple instructions. In this situation, the interrupt latency of the processor is increased because any LDM or STM must complete before the processor can stack the current state and enter the interrupt handler.
Value	Description									
0	No effect.									
1	Disables interruption of load multiple and store multiple instructions. In this situation, the interrupt latency of the processor is increased because any LDM or STM must complete before the processor can stack the current state and enter the interrupt handler.									

Register 55: CPU ID Base (CPUID), offset 0xD00

Note: This register can only be accessed from privileged mode.

The **CPUID** register contains the ARM® Cortex™-M4 processor part number, version, and implementation information.

CPU ID Base (CPUID)

Base 0xE000.E000

Offset 0xD00

Type RO, reset 0x410F.C241

Bit/Field	Name	Type	Reset	Description
31:24	IMP	RO	0x41	Implementer Code Value Description 0x41 ARM
23:20	VAR	RO	0x0	Variant Number Value Description 0x0 The rn value in the rnpn product revision identifier, for example, the 0 in r0p0.
19:16	CON	RO	0xF	Constant Value Description 0xF Always reads as 0xF.
15:4	PARTNO	RO	0xC24	Part Number Value Description 0xC24 Cortex-M4 processor.
3:0	REV	RO	0x1	Revision Number Value Description 0x1 The pn value in the rnpn product revision identifier, for example, the 1 in r0p1.

Register 56: Interrupt Control and State (INTCTRL), offset 0xD04

Note: This register can only be accessed from privileged mode.

The **INCTRL** register provides a set-pending bit for the NMI exception, and set-pending and clear-pending bits for the PendSV and SysTick exceptions. In addition, bits in this register indicate the exception number of the exception being processed, whether there are preempted active exceptions, the exception number of the highest priority pending exception, and whether any interrupts are pending.

When writing to **INCTRL**, the effect is unpredictable when writing a 1 to both the PENDSV and UNPENDSV bits, or writing a 1 to both the PENDSTSET and PENDSTCLR bits.

Interrupt Control and State (INTCTRL)

Bit/Field Name Type Reset Description

31	NMISET	RW	0	NMI Set Pending
Value Description				
0	On a read, indicates an NMI exception is not pending. On a write, no effect.			
1	On a read, indicates an NMI exception is pending. On a write, changes the NMI exception state to pending.			

Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it registers the setting of this bit, and clears this bit on entering the interrupt handler. A read of this bit by the NMI exception handler returns 1 only if the **NMI** signal is reasserted while the processor is executing that handler.

30:29	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
-------	----------	----	-----	---

28	PENDSV	RW	0	PendSV Set Pending
Value Description				
0	On a read, indicates a PendSV exception is not pending. On a write, no effect.			

Setting this bit is the only way to set the PendSV exception state to pending. This bit is cleared by writing a 1 to the UNPENDSV bit.

Bit/Field	Name	Type	Reset	Description						
27	UNPENDSV	WO	0	<p>PendSV Clear Pending</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>On a write, no effect.</td></tr> <tr> <td>1</td><td>On a write, removes the pending state from the PendSV exception.</td></tr> </tbody> </table> <p>This bit is write only; on a register read, its value is unknown.</p>	Value	Description	0	On a write, no effect.	1	On a write, removes the pending state from the PendSV exception.
Value	Description									
0	On a write, no effect.									
1	On a write, removes the pending state from the PendSV exception.									
26	PENDSTSET	RW	0	<p>SysTick Set Pending</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>On a read, indicates a SysTick exception is not pending. Register 57: Vector Table Offset (VTABLE), offset 0xD08

Note: This register can only be accessed from privileged mode.

The **VTABLE** register indicates the offset of the vector table base address from memory address 0x0000.0000.

Vector Table Offset (VTABLE)

Base 0xE000.E000

Offset 0xD08

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:10	OFFSET	RW	0x000.00	Vector Table Offset When configuring the OFFSET field, the offset must be aligned to the number of exception entries in the vector table. Because there are 112 interrupts, the offset must be aligned on a 1024-byte boundary.
9:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 58: Application Interrupt and Reset Control (APINT), offset 0xD0C

Note: This register can only be accessed from privileged mode.

The APINT register provides priority grouping control for the exception model, endian status for data accesses, and reset control of the system. To write to this register, 0x05FA must be written to the VECTKEY field, otherwise the write is ignored.

The PRIGROUP field indicates the position of the binary point that splits the INT_x fields in the **Interrupt Priority (PRI_x)** registers into separate group priority and subpriority fields. Table 3-9 on page 181 shows how the PRIGROUP value controls this split. The bit numbers in the Group Priority Field and Subpriority Field columns in the table refer to the bits in the INTA field. For the INTB field, the corresponding bits are 15:13; for INTC, 23:21; and for INTD, 31:29.

Note: Determining preemption of an exception uses only the group priority field.

Table 3-9. Interrupt Priority Levels

PRIGROUP Bit Field	Binary Point ^a	Group Priority Field	Subpriority Field	Group Priorities	Subpriorities
0x0 - 0x4	bxxx.	[7:5]	None	8	1
0x5	bxx.y	[7:6]	[5]	4	2
0x6	bx.yy	[7]	[6:5]	2	4
0x7	b.yyy	None	[7:5]	1	8

a. INT_x field showing the binary point. An x denotes a group priority field bit, and a y denotes a subpriority field bit.

Application Interrupt and Reset Control (APINT)

Base 0xE000.E000
Offset 0xD0C
Type RW, reset 0xFA05.0000

Bit/Field	Name	Type	Reset	Description
31:16	VECTKEY	RW	0xFA05	Register Key This field is used to guard against accidental writes to this register. 0x05FA must be written to this field in order to change the bits in this register. On a read, 0xFA05 is returned.
15	ENDIANESS	RO	0	Data Endianess The Tiva™ C Series implementation uses only little-endian mode so this is cleared to 0.
14:11	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
10:8	PRIGROUP	RW	0x0	Interrupt Priority Grouping This field determines the split of group priority from subpriority (see Table 3-9 on page 181 for more information).
7:3	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	SYSRESREQ	WO	0	System Reset Request Value Description 0 No effect. 1 Resets the core and all on-chip peripherals except the Debug interface. This bit is automatically cleared during the reset of the core and reads as 0.
1	VECTCLRACT	WO	0	Clear Active NMI / Fault This bit is reserved for Debug use and reads as 0. This bit must be written as a 0, otherwise behavior is unpredictable.
0	VECTRESET	WO	0	System Reset This bit is reserved for Debug use and reads as 0. This bit must be written as a 0, otherwise behavior is unpredictable.

Register 59: System Control (SYSCTRL), offset 0xD10

Note: This register can only be accessed from privileged mode.

The **SYSCTRL** register controls features of entry to and exit from low-power state.

System Control (SYSCTRL)

Base 0xE000.E000
Offset 0xD10
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	SEVONPEND	RW	0	<p>Wake Up on Pending</p> <p>Value Description</p> <p>0 Only enabled interrupts or events can wake up the processor; disabled interrupts are excluded.</p> <p>1 Enabled events and all interrupts, including disabled interrupts, can wake up the processor.</p> <p>When an event or interrupt enters the pending state, the event signal wakes up the processor from WFE. If the processor is not waiting for an event, the event is registered and affects the next WFE.</p> <p>The processor also wakes up on execution of a SEV instruction or an external event.</p>
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	SLEEPDEEP	RW	0	<p>Deep Sleep Enable</p> <p>Value Description</p> <p>0 Use Sleep mode as the low power mode.</p> <p>1 Use Deep-sleep mode as the low power mode.</p>

Bit/Field	Name	Type	Reset	Description

0	When returning from Handler mode to Thread mode, do not sleep when returning to Thread mode.							
1	When returning from Handler mode to Thread mode, enter sleep or deep sleep on return from an ISR.							
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				

Register 60: Configuration and Control (CFGCTRL), offset 0xD14

Note: This register can only be accessed from privileged mode.

The **CFGCTRL** register controls entry to Thread mode and enables: the handlers for NMI, hard fault and faults escalated by the **FAULTMASK** register to ignore bus faults; trapping of divide by zero and unaligned accesses; and access to the **SWTRIG** register by unprivileged software (see page 173).

Configuration and Control (CFGCTRL)

Base 0xE000.E000
Offset 0xD14
Type RW, reset 0x0000.0200

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	STKALIGN	RW	1	<p>Stack Alignment on Exception Entry</p> <p>Value Description</p> <p>0 The stack is 4-byte aligned.</p> <p>1 The stack is 8-byte aligned.</p> <p>On exception entry, the processor uses bit 9 of the stacked PSR to indicate the stack alignment. On return from the exception, it uses this stacked bit to restore the correct stack alignment.</p>
8	BFHFNMIGN	RW	0	<p>Ignore Bus Fault in NMI and Fault</p> <p>This bit enables handlers with priority -1 or -2 to ignore data bus faults caused by load and store instructions. The setting of this bit applies to the hard fault, NMI, and FAULTMASK escalated handlers.</p> <p>Value Description</p> <p>0 Data bus faults caused by load and store instructions cause a lock-up.</p> <p>1 Handlers running at priority -1 and -2 ignore data bus faults caused by load and store instructions.</p> <p>Set this bit only when the handler and its data are in absolutely safe memory. The normal use of this bit is to probe system devices and bridges to detect control path problems and fix them.</p>
7:5	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description						
4	DIV0	RW	0	<p>Trap on Divide by 0</p> <p>This bit enables faulting or halting when the processor executes an SDIV or UDIV instruction with a divisor of 0.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Do not trap on divide by 0. 4:0	reserved	RO	0x0.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 64: System Handler Control and State (SYSHNDCTRL), offset 0xD24

Note: This register can only be accessed from privileged mode.

The **SYSHNDCTRL** register enables the system handlers, and indicates the pending status of the usage fault, bus fault, memory management fault, and SVC exceptions as well as the active status of the system handlers.

If a system handler is disabled and the corresponding fault occurs, the processor treats the fault as a hard fault.

This register can be modified to change the pending or active status of system exceptions. An OS kernel can write to the active bits to perform a context switch that changes the current exception type.

Caution – Software that changes the value of an active bit in this register without correct adjustment to the stacked content can cause the processor to generate a fault exception. Ensure software that writes to this register retains and subsequently restores the current active status.

If the value of a bit in this register must be modified after enabling the system handlers, a read-modify-write procedure must be used to ensure that only the required bit is modified.

0	MEMA	RW	0	Memory Management Fault Active
Value Description				
0 Memory management fault is not active.				
1 Memory management fault is active.				
This bit can be modified to change the active status of the memory management fault exception, however, see the Caution above before setting this bit.				

Register 65: Configurable Fault Status (FAULTSTAT), offset 0xD28

Note: This register can only be accessed from privileged mode.

The **FAULTSTAT** register indicates the cause of a memory management fault, bus fault, or usage fault. Each of these functions is assigned to a subregister as follows:

- **Usage Fault Status (UFAULTSTAT)**, bits 31:16
- **Bus Fault Status (BFAULTSTAT)**, bits 15:8
- **Memory Management Fault Status (MFAULTSTAT)**, bits 7:0

FAULTSTAT is byte accessible. **FAULTSTAT** or its subregisters can be accessed as follows:

- The complete **FAULTSTAT** register, with a word access to offset 0xD28
- The **MFAULTSTAT**, with a byte access to offset 0xD28
- The **MFAULTSTAT** and **BFAULTSTAT**, with a halfword access to offset 0xD28
- The **BFAULTSTAT**, with a byte access to offset 0xD29
- The **UFAULTSTAT**, with a halfword access to offset 0xD2A

Bits are cleared by writing a 1 to them.

In a fault handler, the true faulting address can be determined by:

1. Read and save the **Memory Management Fault Address (MMADDR)** or **Bus Fault Address (FAULTADDR)** value.
2. Read the **MMARV** bit in **MFAULTSTAT**, or the **BFARV** bit in **BFAULTSTAT** to determine if the **MMADDR** or **FAULTADDR** contents are valid.

Software must follow this sequence because another higher priority exception might change the **MMADDR** or **FAULTADDR** value. For example, if a higher priority handler preempts the current fault handler, the other fault might change the **MMADDR** or **FAULTADDR** value.

	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31	DBG	RW1C	0	Debug Event This bit is reserved for Debug use. This bit must be written as a 0, otherwise behavior is unpredictable.
30	FORCED	RW1C	0	Forced Hard Fault Value Description 0 No forced hard fault has occurred. 1 A forced hard fault has been generated by escalation of a fault with configurable priority that cannot be handled, either because of priority or because it is disabled. When this bit is set, the hard fault handler must read the other fault status registers to find the cause of the fault. This bit is cleared by writing a 1 to it.
29:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	VECT	RW1C	0	Vector Table Read Fault Value Description 0 No bus fault has occurred on a vector table read. 1 A bus fault occurred on a vector table read. This error is always handled by the hard fault handler. When this bit is set, the PC value stacked for the exception return points to the instruction that was preempted by the exception. This bit is cleared by writing a 1 to it.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 67: Memory Management Fault Address (MMADDR), offset 0xD34

Note: This register can only be accessed from privileged mode.

The **MMADDR** register contains the address of the location that generated a memory management fault. When an unaligned access faults, the address in the **MMADDR** register is the actual address that faulted. Because a single read or write instruction can be split into multiple aligned accesses, the fault address can be any address in the range of the requested access size. Bits in the **Memory Management Fault Status (MFAULTSTAT)** register indicate the cause of the fault and whether the value in the **MMADDR** register is valid (see page 194).

Memory Management Fault Address (MMADDR)

Base 0xE000.E000

Offset 0xD34

Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	RW	-	Fault Address When the MMARV bit of MFAULTSTAT is set, this field holds the address of the location that generated the memory management fault.

Register 68: Bus Fault Address (FAULTADDR), offset 0xD38

Note: This register can only be accessed from privileged mode.

The **FAULTADDR** register contains the address of the location that generated a bus fault. When an unaligned access faults, the address in the **FAULTADDR** register is the one requested by the instruction, even if it is not the address of the fault. Bits in the **Bus Fault Status (BFAULTSTAT)** register indicate the cause of the fault and whether the value in the **FAULTADDR** register is valid (see page 194).

Bus Fault Address (FAULTADDR)

Base 0xE000.E000

Offset 0xD38

Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	RW	-	Fault Address When the FAULTADDRV bit of BFAULTSTAT is set, this field holds the address of the location that generated the bus fault.

3.6 Memory Protection Unit (MPU) Register Descriptions

This section lists and describes the Memory Protection Unit (MPU) registers, in numerical order by address offset.

The MPU registers can only be accessed from privileged mode.

Register 69: MPU Type (MPUTYPE), offset 0xD90

Note: This register can only be accessed from privileged mode.

The **MPUTYPE** register indicates whether the MPU is present, and if so, how many regions it supports.

MPU Type (MPUTYPE)

Base 0xE000.E000

Offset 0xD90

Type RO, reset 0x0000.0800

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:16	IREGION	RO	0x00	Number of I Regions This field indicates the number of supported MPU instruction regions. This field always contains 0x00. The MPU memory map is unified and is described by the DREGION field.
15:8	DREGION	RO	0x08	Number of D Regions Value Description 0x08 Indicates there are eight supported MPU data regions.
7:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	SEPARATE	RO	0	Separate or Unified MPU Value Description 0 Indicates the MPU is unified.

Register 70: MPU Control (MPUCTRL), offset 0xD94

Note: This register can only be accessed from privileged mode.

The **MPUCTRL** register enables the MPU, enables the default memory map background region, and enables use of the MPU when in the hard fault, Non-maskable Interrupt (NMI), and **Fault Mask Register (FAULTMASK)** escalated handlers.

When the `ENABLE` and `PRIVDEFEN` bits are both set:

- For privileged accesses, the default memory map is as described in “Memory Model” on page 112. Any access by privileged software that does not address an enabled memory region behaves as defined by the default memory map.
 - Any access by unprivileged software that does not address an enabled memory region causes a memory management fault.

Execute Never (XN) and Strongly Ordered rules always apply to the System Control Space regardless of the value of the ENABLE bit.

When the `ENABLE` bit is set, at least one region of the memory map must be enabled for the system to function unless the `PRIVDEFEN` bit is set. If the `PRIVDEFEN` bit is set and no regions are enabled, then only privileged software can operate.

When the `ENABLE` bit is clear, the system uses the default memory map, which has the same memory attributes as if the MPU is not implemented (see Table 2-5 on page 117 for more information). The default memory map applies to accesses from both privileged and unprivileged software.

When the MPU is enabled, accesses to the System Control Space and vector table are always permitted. Other areas are accessible based on regions and whether `PRIVDEFEN` is set.

Unless HFNMIEA is set, the MPU is not enabled when the processor is executing the handler for an exception with priority –1 or –2. These priorities are only possible when handling a hard fault or NMI exception or when **FAULTMASK** is enabled. Setting the HFNMIEA bit enables the MPU when operating with these two priorities.

MPU Control (MPUCTRL)

0	ENABLE	RW	0	<p>MPU Enable</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The MPU is disabled.</td></tr> <tr> <td>1</td><td>The MPU is enabled.</td></tr> </tbody> </table> <p>When the MPU is disabled and the HFNMIENA bit is set, the resulting behavior is unpredictable.</p>	Value	Description	0	The MPU is disabled.	1	The MPU is enabled.
Value	Description									
0	The MPU is disabled.									
1	The MPU is enabled.									

Register 71: MPU Region Number (MPUNUMBER), offset 0xD98

Note: This register can only be accessed from privileged mode.

The **MPUNUMBER** register selects which memory region is referenced by the **MPU Region Base Address (MPUBASE)** and **MPU Region Attribute and Size (MPUATTR)** registers. Normally, the required region number should be written to this register before accessing the **MPUBASE** or the **MPUATTR** register. However, the region number can be changed by writing to the **MPUBASE** register with the **VALID** bit set (see page 207). This write updates the value of the **REGION** field.

MPU Region Number (MPUNUMBER)

Base 0xE000.E000

Offset 0xD98

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	NUMBER	RW	0x0	MPU Region to Access This field indicates the MPU region referenced by the MPUBASE and MPUATTR registers. The MPU supports eight memory regions.

Register 72: MPU Region Base Address (MPUBASE), offset 0xD9C**Register 73: MPU Region Base Address Alias 1 (MPUBASE1), offset 0xDA4****Register 74: MPU Region Base Address Alias 2 (MPUBASE2), offset 0xDAC****Register 75: MPU Region Base Address Alias 3 (MPUBASE3), offset 0xDB4**

Note: This register can only be accessed from privileged mode.

The **MPUBASE** register defines the base address of the MPU region selected by the **MPU Region Number (MPUNUMBER)** register and can update the value of the **MPUNUMBER** register. To change the current region number and update the **MPUNUMBER** register, write the **MPUBASE** register with the **VALID** bit set.

The **ADDR** field is bits 31:N of the **MPUBASE** register. Bits (N-1):5 are reserved. The region size, as specified by the **SIZE** field in the **MPU Region Attribute and Size (MPUATTR)** register, defines the value of N where:

$$N = \log_2(\text{Region size in bytes})$$

If the region size is configured to 4 GB in the **MPUATTR** register, there is no valid **ADDR** field. In this case, the region occupies the complete memory map, and the base address is 0x0000.0000.

The base address is aligned to the size of the region. For example, a 64-KB region must be aligned on a multiple of 64 KB, for example, at 0x0001.0000 or 0x0002.0000.

MPU Region Base Address (MPUBASE)

Base 0xE000.E000

Offset 0xD9C

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:5	ADDR	RW	0x0000.0000	<p>Base Address Mask</p> <p>Bits 31:N in this field contain the region base address. The value of N depends on the region size, as shown above. The remaining bits (N-1):5 are reserved.</p> <p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>

Bit/Field	Name	Type	Reset	Description						
4	VALID	WO	0	<p>Region Number Valid</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The MPUNUMBER register is not changed and the processor updates the base address for the region specified in the MPUNUMBER register and ignores the value of the REGION field.</td></tr> <tr> <td>1</td><td>The MPUNUMBER register is updated with the value of the REGION field and the base address is updated for the region specified in the REGION field.</td></tr> </tbody> </table> <p>This bit is always read as 0.</p>	Value	Description	0	The MPUNUMBER register is not changed and the processor updates the base address for the region specified in the MPUNUMBER register and ignores the value of the REGION field.	1	The MPUNUMBER register is updated with the value of the REGION field and the base address is updated for the region specified in the REGION field.
Value	Description									
0	The MPUNUMBER register is not changed and the processor updates the base address for the region specified in the MPUNUMBER register and ignores the value of the REGION field.									
1	The MPUNUMBER register is updated with the value of the REGION field and the base address is updated for the region specified in the REGION field.									
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
2:0	REGION	RW	0x0	<p>Region Number</p> <p>On a write, contains the value to be written to the MPUNUMBER register. On a read, returns the current region number in the MPUNUMBER register.</p>						

Register 76: MPU Region Attribute and Size (MPUATTR), offset 0xDA0**Register 77: MPU Region Attribute and Size Alias 1 (MPUATTR1), offset 0xDA8****Register 78: MPU Region Attribute and Size Alias 2 (MPUATTR2), offset 0xDB0****Register 79: MPU Region Attribute and Size Alias 3 (MPUATTR3), offset 0xDB8**

Note: This register can only be accessed from privileged mode.

The **MPUATTR** register defines the region size and memory attributes of the MPU region specified by the **MPU Region Number (MPUNUMBER)** register and enables that region and any subregions.

The **MPUATTR** register is accessible using word or halfword accesses with the most-significant halfword holding the region attributes and the least-significant halfword holds the region size and the region and subregion enable bits.

The MPU access permission attribute bits, XN, AP, TEX, S, C, and B, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

The SIZE field defines the size of the MPU memory region specified by the **MPUNUMBER** register as follows:

$$(\text{Region size in bytes}) = 2^{(\text{SIZE}+1)}$$

The smallest permitted region size is 32 bytes, corresponding to a SIZE value of 4. Table 3-10 on page 209 gives example SIZE values with the corresponding region size and value of N in the **MPU Region Base Address (MPUBASE)** register.

Table 3-10. Example SIZE Field Values

SIZE Encoding	Region Size	Value of N ^a	Note
00100b (0x4)	32 B	5	Minimum permitted size
01001b (0x9)	1 KB	10	-
10011b (0x13)	1 MB	20	-
11101b (0x1D)	1 GB	30	-
11111b (0x1F)	4 GB	No valid ADDR field in MPUBASE ; the region occupies the complete memory map.	Maximum possible size

a. Refers to the N parameter in the **MPUBASE** register (see page 207).

MPU Region Attribute and Size (MPUATTR)

3.7 Floating-Point Unit (FPU) Register Descriptions

This section lists and describes the Floating-Point Unit (FPU) registers, in numerical order by address offset.

Register 80: Coprocessor Access Control (CPAC), offset 0xD88

The **CPAC** register specifies the access privileges for coprocessors.

Coprocessor Access Control (CPAC)

Base 0xE000.E000
Offset 0xD88
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:22	CP11	RW	0x00	CP11 Coprocessor Access Privilege
		Value	Description	
		0x0	Access Denied	Any attempted access generates a NOCP Usage Fault.
		0x1	Privileged Access Only	An unprivileged access generates a NOCP fault.
		0x2	Reserved	The result of any access is unpredictable.
		0x3	Full Access	
21:20	CP10	RW	0x00	CP10 Coprocessor Access Privilege
		Value	Description	
		0x0	Access Denied	Any attempted access generates a NOCP Usage Fault.
		0x1	Privileged Access Only	An unprivileged access generates a NOCP fault.
		0x2	Reserved	The result of any access is unpredictable.
		0x3	Full Access	
19:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 81: Floating-Point Context Control (FPCC), offset 0xF34

The FPCC register sets or returns FPU control data.

Floating-Point Context Control (FPCC)

Base 0xE000.E000
Offset 0xF34
Type RW, reset 0xC000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
31	ASPN	RW	1	Automatic State Preservation Enable When set, enables the use of the FRACTV bit in the CONTROL register on execution of a floating-point instruction. This results in automatic hardware state preservation and restoration, for floating-point context, on exception entry and exit.
	Important: Two bits control when FPCA can be enabled: the ASPEN bit in the Floating-Point Context Control (FPCC) register and the DISFPCA bit in the Auxiliary Control (ACTLR) register.			
30	LSPEN	RW	1	Lazy State Preservation Enable When set, enables automatic lazy state preservation for floating-point context.
29:9	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MONRDY	RW	0	Monitor Ready When set, DebugMonitor is enabled and priority permits setting MON_PEND when the floating-point stack frame was allocated.
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	BFRDY	RW	0	Bus Fault Ready When set, BusFault is enabled and priority permitted setting the BusFault handler to the pending state when the floating-point stack frame was allocated.
5	MMRDY	RW	0	Memory Management Fault Ready When set, MemManage is enabled and priority permitted setting the MemManage handler to the pending state when the floating-point stack frame was allocated.

Bit/Field	Name	Type	Reset	Description
4	HFRDY	RW	0	Hard Fault Ready When set, priority permitted setting the HardFault handler to the pending state when the floating-point stack frame was allocated.
3	THREAD	RW	0	Thread Mode When set, mode was Thread Mode when the floating-point stack frame was allocated.
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	USER	RW	0	User Privilege Level When set, privilege level was user when the floating-point stack frame was allocated.
0	LSPACT	RW	0	Lazy State Preservation Active When set, Lazy State preservation is active. Floating-point stack frame has been allocated but saving state to it has been deferred.

Register 82: Floating-Point Context Address (FPCA), offset 0xF38

The **FPCA** register holds the location of the unpopulated floating-point register space allocated on an exception stack frame.

Floating-Point Context Address (FPCA)

Base 0xE000.E000

Offset 0xF38

Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:3	ADDRESS	RW	-	Address The location of the unpopulated floating-point register space allocated on an exception stack frame.
2:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 83: Floating-Point Default Status Control (FPDSC), offset 0xF3C

The **FPDSC** register holds the default values for the **Floating-Point Status Control (FPSC)** register.

Floating-Point Default Status Control (FPDSC)

Base 0xE000.E000
Offset 0xF3C
Type RW, reset 0x0000.0000

25	DN	RW	-	DN Bit Default This bit holds the default value for the DN bit in the FPSC register.
24	FZ	RW	-	FZ Bit Default This bit holds the default value for the FZ bit in the FPSC register.
23:22	RMODE	RW	-	RMODE Bit Default This bit holds the default value for the RMODE bit field in the FPSC register.
				Value Description
				0x0 Round to Nearest (RN) mode
				0x1 Round towards Plus Infinity (RP) mode
				0x2 Round towards Minus Infinity (RM) mode
				0x3 Round towards Zero (RZ) mode
21:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

4 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The TM4C129XKCZAD JTAG controller works with the ARM JTAG controller built into the Cortex-M4F core by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while JTAG instructions select the TDO output. The multiplexer is controlled by the JTAG controller, which has comprehensive programming for the ARM, Tiva™ C Series microcontroller, and unimplemented JTAG instructions.

The TM4C129XKCZAD JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions: BYPASS, IDCODE, SAMPLE/PRELOAD, and EXTEST
- ARM additional instructions: APACC, DPACC and ABORT
- Integrated ARM Serial Wire Debug (SWD)
 - Serial Wire JTAG Debug Port (SWJ-DP)
 - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
 - Data Watchpoint and Trace (DWT) unit for implementing watchpoints, trigger resources, and system profiling
 - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
 - Embedded Trace Macrocell (ETM) for instruction trace capture
 - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

See the *ARM® Debug Interface V5 Architecture Specification* for more information on the ARM JTAG controller.

4.1 Block Diagram

Figure 4-1. JTAG Module Block Diagram

4.2 Signal Description

The following table lists the external signals of the JTAG/SWD controller and describes the function of each. The JTAG/SWD controller signals are alternate functions for some GPIO signals, however note that the reset state of the pins is for the JTAG/SWD function. The JTAG/SWD controller signals are under commit protection and require a special process to be configured as GPIOs, see “Commit Control” on page 781. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the JTAG/SWD controller signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) is set to choose the JTAG/SWD function. The number in parentheses is the encoding that must be programmed into the PMCn field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the JTAG/SWD controller signals to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 769.

Table 4-1. JTAG_SWD_SWO Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
SWCLK	B15	PC0 (1)	I	TTL	JTAG/SWD CLK.
SWDIO	C15	PC1 (1)	I/O	TTL	JTAG TMS and SWDIO.
SWO	C14	PC3 (1)	O	TTL	JTAG TDO and SWO.
TCK	B15	PC0 (1)	I	TTL	JTAG/SWD CLK.
TDI	D14	PC2 (1)	I	TTL	JTAG TDI.
TDO	C14	PC3 (1)	O	TTL	JTAG TDO and SWO.
TMS	C15	PC1 (1)	I	TTL	JTAG TMS and SWDIO.

4.3 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 4-1 on page 218. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the TCK and TMS inputs. The current state of the TAP controller depends on the sequence of values captured on TMS at the rising edge of TCK. The TAP controller determines when the serial shift chains capture new data, shift data from TDI towards TDO, and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like EXTEST, operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the BYPASS instruction to ensure that the serial path between TDI and TDO is always connected (see Table 4-3 on page 226 for a list of implemented instructions).

See “JTAG and Boundary Scan” on page 2104 for JTAG timing diagrams.

Depending on the reset source, the effect on the JTAG module varies. The following reset sources reset the entire JTAG Module:

- Externally generated Power-On Reset

The following reset sources reset only the JTAG pin configuration:

- $\overline{\text{RST}}$ pin Power-On Reset
- Brown-Out Power-On Reset
- Watchdog Power-On Reset
- HIB Module Power-On Reset
- $\overline{\text{RST}}$ pin System Reset
- Brown-Out System Reset
- Software System Reset Request (using the SYSRESREQ bit in the APINT register)
- Software Peripheral Reset
- Watchdog System Reset
- HIB Module System Reset

4.3.1 JTAG Interface Pins

The JTAG interface consists of four standard pins: TCK, TMS, TDI, and TDO. These pins and their associated state after a power-on reset or reset caused by the $\overline{\text{RST}}$ input are given in Table 4-2. Detailed information on each pin follows.

Note: The following pins are configured as JTAG port pins out of reset. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 769 for information on how to reprogram the configuration of these pins.

Table 4-2. JTAG Port Pins State after Power-On Reset or RST assertion

Pin Name	Data Direction	Internal Pull-Up	Internal Pull-Down	Drive Strength	Drive Value
TCK	Input	Enabled	Disabled	N/A	N/A
TMS	Input	Enabled	Disabled	N/A	N/A
TDI	Input	Enabled	Disabled	N/A	N/A
TDO	Output	Enabled	Disabled	2-mA driver	High-Z

4.3.1.1 Test Clock Input (TCK)

The TCK pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks and to ensure that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components. During normal operation, TCK is driven by a free-running clock with a nominal 50% duty cycle. When necessary, TCK can be stopped at 0 or 1 for extended periods of time. While TCK is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the TCK pin is enabled after reset, assuring that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the TCK pin is constantly being driven by an external source (see page 805 and page 807).

4.3.1.2 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state may be entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG module and associated registers are reset to their default values. This procedure should be performed to initialize the JTAG controller. The JTAG Test Access Port state machine can be seen in its entirety in Figure 4-2 on page 222.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost (see page 805).

4.3.1.3 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, may present this data to the proper shift register chain. Because the TDI pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI; otherwise JTAG communication could be lost (see page 805).

4.3.1.4 Test Data Output (TDO)

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the chain being accessed. In order to save power when the JTAG port is not being used, the TDO pin is placed in an inactive drive state when not actively shifting out data. Because TDO can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TDO to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDO pin is enabled after reset, assuring that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states (see page 805 and page 807).

Note: If the device fails initialization during reset, the hardware toggles the TDO output as an indication of failure. Thus, during board layout, designers should not designate the TDO pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

4.3.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 4-2. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR). In order to reset the JTAG module after the microcontroller has been powered on, the TMS input must be held HIGH for five TCK clock cycles, resetting the TAP controller and all associated JTAG chains. Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

Figure 4-2. Test Access Port State Machine

4.3.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller's CAPTURE states and allows this information to be shifted out on TDO during the TAP controller's SHIFT states. While the sampled data is being shifted out of the chain on TDO, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller's UPDATE states. Each of the shift registers is discussed in detail in "Register Descriptions" on page 225.

4.3.4 Operational Considerations

Certain operational parameters must be considered when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

4.3.4.1 GPIO Functionality

When the microcontroller is reset with either a POR or \overline{RST} , the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality ($DEN[3:0]$ set in the **Port C GPIO Digital Enable (GPIODEN)** register), enabling the pull-up resistors ($PUE[3:0]$ set in the **Port C GPIO Pull-Up Select (GPIOPUR)** register), disabling the pull-down resistors ($PDE[3:0]$ cleared in the **Port C GPIO Pull-Down Select (GPIOPDR)** register) and enabling the

alternate hardware function (`AFSEL[3:0]`) set in the **Port C GPIO Alternate Function Select (GPIOAFSEL)** register) on the JTAG/SWD pins. See page 799, page 805, page 807, and page 810.

It is possible for software to configure these pins as GPIOs after reset by clearing `AFSEL[3:0]` in the **Port C GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides four more GPIOs for use in the design.

Caution – It is possible to create a software sequence that prevents the debugger from connecting to the TM4C129XKCZAD microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger. In the case that the software routine is not implemented and the device is locked out of the part, this issue can be solved by using the TM4C129XKCZAD Flash Programmer "Unlock" feature. Please refer to [LMFLASHPROGRAMMER](#) on the TI web for more information.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the `NMI` pin (see “Signal Tables” on page 2032 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 799), **GPIO Pull Up Select (GPIOPUR)** register (see page 805), **GPIO Pull-Down Select (GPIOPDR)** register (see page 807), and **GPIO Digital Enable (GPIODEN)** register (see page 810) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 812) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 813) have been set.

4.3.4.2 Communication with JTAG/SWD

Because the debug clock and the system clock can be running at different frequencies, care must be taken to maintain reliable communication with the JTAG/SWD interface. In the Capture-DR state, the result of the previous transaction, if any, is returned, together with a 3-bit ACK response. Software should check the ACK response to see if the previous operation has completed before initiating a new transaction. Alternatively, if the system clock is at least 8 times faster than the debug clock (`TCK` or `SWCLK`), the previous operation has enough time to complete and the ACK bits do not have to be checked.

4.3.4.3 Recovering a "Locked" Microcontroller

Note: Performing the sequence below restores the non-volatile registers discussed in “Non-Volatile Register Programming-- Flash Memory Resident Registers” on page 643 to their factory default values. The mass erase of the Flash memory caused by the sequence below occurs prior to the non-volatile registers being restored.

In addition, the EEPROM is erased and its wear-leveling counters are returned to factory default values when performing the sequence below.

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug port unlock sequence that can be used to recover the microcontroller. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the microcontroller in reset mass erases the Flash memory. The debug port unlock sequence is:

1. Assert and hold the `RST` signal.
2. Apply power to the device.

3. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence on the section called “JTAG-to-SWD Switching” on page 224.
4. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence on the section called “SWD-to-JTAG Switching” on page 225.
5. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
6. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
7. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
8. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
9. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
10. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
11. Perform steps 1 and 2 of the JTAG-to-SWD switch sequence.
12. Perform steps 1 and 2 of the SWD-to-JTAG switch sequence.
13. Release the $\overline{\text{RST}}$ signal.
14. Wait TBD ms.
15. Power-cycle the microcontroller.

4.3.4.4 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M4F core without having to perform, or have any knowledge of, JTAG cycles. This integration is accomplished with a SWD preamble that is issued before the SWD session begins.

The switching preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequence of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM® Debug Interface V5 Architecture Specification*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This instance is the only one where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

JTAG-to-SWD Switching

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send the switching preamble to the microcontroller. The 16-bit TMS/SWDIO command for switching to SWD mode is defined as b1110.0111.1001.1110, transmitted LSB first. This command can also be represented as 0xE79E when transmitted LSB first. The

complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset states.
2. Send the 16-bit JTAG-to-SWD switch command, 0xE79E, on TMS / SWDIO.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in SWD mode before sending the switch sequence, the SWD goes into the line reset state.

To verify that the Debug Access Port (DAP) has switched to the Serial Wire Debug (SWD) operating mode, perform a SWD READID operation. The ID value can be compared against the device's known ID to verify the switch.

SWD-to-JTAG Switching

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch command to the microcontroller. The 16-bit TMS / SWDIO command for switching to JTAG mode is defined as b1110.0111.0011.1100, transmitted LSB first. This command can also be represented as 0xE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that both JTAG and SWD are in their reset states.
2. Send the 16-bit SWD-to-JTAG switch command, 0xE73C, on TMS / SWDIO.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO High to ensure that if SWJ-DP was already in JTAG mode before sending the switch sequence, the JTAG goes into the Test Logic Reset state.

To verify that the Debug Access Port (DAP) has switched to the JTAG operating mode, set the JTAG Instruction Register (IR) to the IDCODE instruction and shift out the Data Register (DR). The DR value can be compared against the device's known IDCODE to verify the switch.

4.4 Initialization and Configuration

After a Power-On-Reset or an external reset ($\overline{\text{RST}}$), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. To return the pins to their JTAG functions, enable the four JTAG pins ($\text{PC}[3:0]$) for their alternate function using the **GPIOAFSEL** register. In addition to enabling the alternate functions, any other changes to the GPIO pad configurations on the four JTAG pins ($\text{PC}[3:0]$) should be returned to their default settings.

4.5 Register Descriptions

The registers in the JTAG TAP Controller or Shift Register chains are not memory mapped and are not accessible through the on-chip Advanced Peripheral Bus (APB). Instead, the registers within the JTAG controller are all accessed serially through the TAP Controller. These registers include the Instruction Register and the six Data Registers.

4.5.1 Instruction Register (IR)

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain connected between the JTAG TDI and TDO pins with a parallel load register. When the TAP Controller is placed in the correct states, bits can be shifted into the IR. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the IR bits is shown in Table 4-3. A detailed explanation of each instruction, along with its associated Data Register, follows.

Table 4-3. JTAG Instruction Register Commands

IR[3:0]	Instruction	Description
0x0	EXTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.
0x2	SAMPLE / PRELOAD	Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in.
0x8	ABORT	Shifts data into the ARM Debug Port Abort Register.
0xA	DPACC	Shifts data into and out of the ARM DP Access Register.
0xB	APACC	Shifts data into and out of the ARM AC Access Register.
0xE	IDCODE	Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.
0xF	BYPASS	Connects TDI to TDO through a single Shift Register chain.
All Others	Reserved	Defaults to the BYPASS instruction to ensure that TDI is always connected to TDO.

4.5.1.1 EXTEST Instruction

The EXTEST instruction is not associated with its own Data Register chain. Instead, the EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. With tests that drive known values out of the controller, this instruction can be used to verify connectivity. While the EXTEST instruction is present in the Instruction Register, the Boundary Scan Data Register can be accessed to sample and shift out the current data and load new data into the Boundary Scan Data Register.

4.5.1.2 SAMPLE/PRELOAD Instruction

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TDO. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out on TDO while the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI. Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST instruction to drive data into or out of the controller. See “Boundary Scan Data Register” on page 228 for more information.

4.5.1.3 ABORT Instruction

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TDO. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. See the “ABORT Data Register” on page 229 for more information.

4.5.1.4 DPACC Instruction

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TDO. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. See “DPACC Data Register” on page 229 for more information.

4.5.1.5 APACC Instruction

The APACC instruction connects the associated APACC Data Register chain between TDI and TDO. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. See “APACC Data Register” on page 228 for more information.

4.5.1.6 IDCODE Instruction

The IDCODE instruction connects the associated IDCODE Data Register chain between TDI and TDO. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure input and output data streams. IDCODE is the default instruction loaded into the JTAG Instruction Register when a Power-On-Reset (POR) is asserted, or the Test-Logic-Reset state is entered. See “IDCODE Data Register” on page 227 for more information.

4.5.1.7 BYPASS Instruction

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TDO. This instruction is used to create a minimum length serial path between the TDI and TDO ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. See “BYPASS Data Register” on page 228 for more information.

4.5.2 Data Registers

The JTAG module contains six Data Registers. These serial Data Register chains include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT and are discussed in the following sections.

4.5.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-3. The standard requires that every JTAG-compliant microcontroller implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x4BA0.0477. This value allows the debuggers to automatically configure themselves to work correctly with the Cortex-M4F during debug.

Figure 4-3. IDCODE Register Format

4.5.2.2 BYPASS Data Register

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 4-4. The standard requires that every JTAG-compliant microcontroller implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This definition allows auto-configuration test tools to determine which instruction is the default instruction.

Figure 4-4. BYPASS Register Format

4.5.2.3 Boundary Scan Data Register

The format of the Boundary Scan Data Register is shown in Figure 4-5. Each GPIO pin, starting with a GPIO pin next to the JTAG port pins, is included in the Boundary Scan Data Register. Each GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as shown in the figure.

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain to be verified. The sampling of these values occurs on the rising edge of TCK in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST instruction. The EXTEST instruction forces data out of the controller.

Figure 4-5. Boundary Scan Register Format

4.5.2.4 APACC Data Register

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

4.5.2.5 DPACC Data Register

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

4.5.2.6 ABORT Data Register

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM® Debug Interface V5 Architecture Specification*.

5 System Control

System control configures the overall operation of the device and provides information about the device. Configurable features include reset control, NMI operation, power control, clock control, and low-power modes.

5.1 Signal Description

The following table lists the external signals of the System Control module and describes the function of each. The **NMI** signal is the alternate function for two GPIO signals, which default to GPIO after reset. The **NMI** pins are under commit protection and require a special process to be configured as any alternate function or to subsequently return to the GPIO function. See “Commit Control” on page 781 for more information. The column in the table below titled “Pin Mux/Pin Assignment” lists the GPIO pin placement for the **NMI** signal. The number in parentheses next to the pin placement listed is the encoding that must be programmed into the **PMCh** field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the **NMI** signal to the specified GPIO port pin. In addition, the **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the NMI function. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 769. The remaining signals listed in the table (with the word “fixed” in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Table 5-1. System Control & Clocks Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
DIVSCLK	A13	PQ4 (7)	O	TTL	An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock.
GNDX2	D18	fixed	-	Power	GND for the MOSC. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.
NMI	B2 B7	PD7 (8) PE7 (8)	I	TTL	Non-maskable interrupt.
OSC0	E19	fixed	I	Analog	Main oscillator crystal input or an external clock reference input.
OSC1	D19	fixed	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
RST	P18	fixed	I	TTL	System reset input.

5.2 Functional Description

The System Control module provides the following capabilities:

- Device identification, see “Device Identification” on page 231
- Configurable control of reset, power, and clock sources.
- System control (Run, Sleep, and Deep-Sleep modes), see “System Control” on page 250

5.2.1 Device Identification

Read-only registers in the system control module provide information about the microcontroller, such as version, part number, pin count, operating temperature range and available peripherals on the device. The **Device Identification 0 (DID0)** (page 266) and **Device Identification 1 (DID1)** (page 268) registers provide details about the device's version, package, temperature range, and so on. The Peripheral Present registers starting at system control offset 0x300, such as the **Watchdog Timer Peripheral Present (PPWD)** register, provide information on how many of each type of module are included on the device. Finally, information about the capabilities of the on-chip peripherals are provided at offset 0xFC0 in each peripheral's register space in the Peripheral Properties registers, such as the **GPTM Peripheral Properties (GPTMPP)**.

5.2.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

5.2.2.1 Reset Sources

The TM4C129XKCZAD microcontroller has the following reset sources:

1. Power-on reset (POR) (see page 232).
2. External reset input pin (\overline{RST}) assertion (see page 233).
3. A brown-out detection of V_{DDA} (analog voltage source) or V_{DD} (external voltage source) dropping below its acceptable operating range. (see page 235).
4. Software-initiated reset (with the software reset registers) (see page 236).
5. A watchdog timer reset condition violation (see page 236).
6. Hibernation module event
7. A software restart initiated through a Hardware System Service Request (HSSR)
8. MOSC failure (see page 239).

Table 5-2 provides a summary of results of the various reset operations. Note that the external \overline{RST} pin, the Brown-out detection unit, the HIB module and watchdog timer can all be programmed to generate either a Power-On Reset (POR) or system reset depending on how the **Reset Behavior Control (RESBEHAVCTL)** register at offset 0x1D8 is programmed.

Table 5-2. Reset Sources

Reset Source	Core Reset?	JTAG Reset?	On-Chip Peripherals Reset?
Externally Generated Power-On Reset	Yes	Yes	Yes
\overline{RST} pin Power-On Reset	Yes	Pin Configuration Only	Yes
\overline{RST} pin System Reset	Yes	Pin Configuration Only	Yes
Brown-Out Power-On Reset	Yes	Pin Configuration Only	Yes
Brown-Out System Reset	Yes	Pin Configuration Only	Yes

Table 5-2. Reset Sources (continued)

Reset Source	Core Reset?	JTAG Reset?	On-Chip Peripherals Reset?
Software System Reset Request using the SYSRESREQ bit in the APINT register.	Yes	Pin Configuration Only	Yes
Software System Reset Request using the VECTRESET bit in the APINT register.	Yes	No	No
Software Peripheral Reset	No	Pin Configuration Only	Yes ^a
Watchdog Power-On Reset	Yes	Pin Configuration Only	Yes
Watchdog System Reset	Yes	Pin Configuration Only	Yes
HIB Module Power-On Reset	Yes	Pin Configuration Only	Yes
HIB Module System Reset	Yes	Pin Configuration Only	Yes
HSSR Reset	Yes	Pin Configuration Only	Yes
MOSC Failure Reset	Yes	Pin Configuration Only	Yes

a. Programmable on a module-by-module basis by using the individual peripheral Software Reset Registers starting at System Control offset 0x500

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences. A bit in the **RESC** register can be cleared by writing a 0.

5.2.2.2 Boot Configuration

After Power-On-Reset (POR) and device initialization occurs, the hardware loads the stack pointer from either flash or ROM based on the presence of an application in flash and the state of the **EN** bit in the **BOOTCFG** register. If the flash address 0x0000.0004 contains an erased word (value 0xFFFF.FFFF) or the **EN** bit is of the **BOOTCFG** register is clear, the stack pointer and reset vector pointer are loaded from ROM at address 0x0100.0000 and 0x0100.0004, respectively. The boot loader executes and configures the available boot slave interfaces and waits for an external memory to load its software.

If the check of the Flash at address 0x0000.0004 contains a valid reset vector value and the **BOOTCFG** register does not indicate the boot loader, the boot sequence causes the stack pointer/reset vector fetch from Flash. This application stack pointer and reset vector is loaded and the processor executes the application directly.

Note: If the device fails the initialization phase, it toggles the **TDO** output pin as an indication the device is not executing. This feature is provided for debug purposes.

5.2.2.3 Externally Generated Power-On Reset (POR)

Note: The JTAG controller can be reset by a power-on reset or by holding the **TMS** pin to high for 5 clock cycles.

During an externally generated POR, the internal Power-On Reset (POR) circuit monitors the power supply voltage (V_{DD}) and generates a reset signal to all of the internal logic including JTAG when the power supply ramp reaches a threshold value (V_{POR}). Reset does not complete if specific voltage parameters are not met as defined in the Electrical Characteristics chapter. For applications that require the use of an external reset signal to hold the microcontroller in reset longer than the internal POR, the **RST** input may be used as discussed in “External **RST** Pin” on page 233. Holding this pin active can keep the initialization process from starting even though power-on reset has occurred.

This is useful in in-circuit testing and other situations where it is desirable to delay the operation of the device until an external supervisor has released.

The Power-On Reset sequence is as follows:

1. The microcontroller waits for internal POR to go inactive.
2. The internal reset is released and the core executes a full initialization of the device. Upon completion, the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The internal POR is only active on the initial power-up of the microcontroller, when the microcontroller wakes from hibernation, and when the VDD supply drops below its defined operating limit. Please refer to the Electrical Characteristics chapter for information on exact values. The Power-On Reset timing is shown in “Power and Brown-Out” on page 2105.

5.2.2.4 External RST Pin

When the external $\overline{\text{RST}}$ pin is asserted it initiates a system reset or Power-On Reset depending on what has been configured in the **Reset Behavior Control (RESBEHAVCTL)** Register. If the EXTRES bit field in **RESBEHAVCTL** is set to 0x3 then a simulated full initialization will begin upon $\overline{\text{RST}}$ assertion. If these bits are programmed to 0x2 then a system reset is issued. When EXTRES is set to a 0x0 or 0x1, then the external $\overline{\text{RST}}$ pin performs its default operation upon assertion, which is issuing a full simulated POR.

An external reset pin ($\overline{\text{RST}}$) that is configured to generate a Power-On Reset resets the microcontroller including the core and all the on-chip peripherals. The external reset sequence is as follows:

1. The external reset pin ($\overline{\text{RST}}$) is asserted for the duration specified by T_{MIN} and then deasserted (see “Reset” on page 2110). This generates an internal POR signal.
2. The microcontroller waits for internal POR to go inactive.
3. The internal reset is released and the core executes a full initialization of the device. Upon completion, the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution. Refer to “Reset” on page 2110 for internal reset deassertion timing.

An external reset pin ($\overline{\text{RST}}$) that is configured to generate a system reset will reset the microcontroller including the core and all the on-chip peripherals. The external reset sequence is as follows:

1. The external reset pin ($\overline{\text{RST}}$) is asserted for the duration specified by T_{MIN} and then deasserted (see “Reset” on page 2110).
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

Note: It is recommended that the trace for the $\overline{\text{RST}}$ signal must be kept as short as possible. Be sure to place any components connected to the $\overline{\text{RST}}$ signal as close to the microcontroller as possible.

If the application only uses the internal POR circuit, the $\overline{\text{RST}}$ input must be connected to the power supply (V_{DD}) through an optional pull-up resistor (0 to 100K Ω) as shown in Figure 5-1 on page 234. The $\overline{\text{RST}}$ input has filtering which requires a minimum pulse width in order for the reset pulse to be recognized, see Table 32-14 on page 2110.

To improve noise immunity and/or to delay reset at power up, the $\overline{\text{RST}}$ input may be connected to an RC network as shown in Figure 5-2 on page 234. If the application requires the use of an external reset switch, Figure 5-3 on page 234 shows the proper circuitry to use. In the figures, the R_{PU} and C_1 components define the power-on delay. The external reset timing is shown in Figure 32-11 on page 2111.

Figure 5-1. Basic $\overline{\text{RST}}$ Configuration

Note: $R_{PU} = 0$ to $100\text{ k}\Omega$

Figure 5-2. External Circuitry to Extend Power-On Reset

Note: $R_{PU} = 1\text{ k}\Omega$ to $100\text{ k}\Omega$

$C_1 = 1\text{ nF}$ to $10\text{ }\mu\text{F}$

Figure 5-3. Reset Circuit Controlled by Switch

Note: Typical $R_{PU} = 10\text{ k}\Omega$

Typical $R_S = 470\text{ }\Omega$

$C_1 = 10\text{ nF}$

5.2.2.5 Brown-Out Reset (BOR)

The microcontroller provides a brown-out detection circuit that triggers if the V_{DD} (external) or V_{DDA} (analog) power supply drops below its corresponding brown-out threshold voltage. If a brown-out condition is detected, the system may generate an interrupt, a system reset or a Power-On Reset. The default value at reset is to generate an interrupt.

The application can identify the type of BOR event that occurred by reading the **Power-Temperature Cause (PWRTC)** register. The BOR detection circuits can be programmed to generate a reset, System Control interrupt, or NMI in the **Power-Temp Brown Out Control (PTBOCTL)** register. The default settings at reset are as follows:

- V_{DDA} under BOR detection default setting is for no action to occur.
- V_{DD} under BOR detection default setting is to execute a full POR.

If the user has programmed a field in the **PTBOCTL** to generate a reset, then the **BOR** bit of the **Reset Behavior Control (RESBEHAVCTL)** register can be programmed to further define what type of reset is generated. If the **BOR** field is programmed to 0x3, a full POR is initiated; if is set to 0x2, then a system reset is issued. When the **BOR** field is set to a 0x0 or 0x1, then the Brown-Out detection circuit will perform its default operation upon assertion, which is issuing an interrupt.

Note: V_{DDA} BOR and V_{DD} BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- **BORRIS** bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 272.
- **BORMIS** bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the **BORIM** bit in the **Interrupt Mask Control (IMC)** register has been set. See page 274 and page 276.
- **BOR** bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 278.

In addition, the following bits control both BOR events:

- **BORIM** bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- **VDDA_UBOR0** and **VDD_UBOR0** bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 230 for more information on how to configure these registers.

The brown-out POR reset sequence is as follows:

1. When one of the BOR event triggers occurs, an internal Brown-Out Reset condition is set.
2. If the BOR event has been programmed to generate a reset in the **PTBOCTL** register and the **BOR** bit of the **RESBEHAVCTL** has been set to 0x3, an internal POR reset is asserted.
3. The internal reset is released and the core executes a full initialization of the device. Upon completion, the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution. The application starts after deassertion of internal POR. Refer to “Reset” on page 2110 for BOR internal reset deassertion timing.

The brown-out system reset sequence is as follows:

1. When one of the BOR event triggers occurs, an internal Brown-Out Reset condition is set.
2. If the BOR event has been programmed to generate a reset in the **PTBOCTL** register and the BOR bit of the **RESBEHAVCTL** has been set to 0x2, an internal reset is asserted.
3. The internal reset is released and the microcontroller fetches and loads the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The result of a brown-out reset is equivalent to that of an assertion of the external **RST** input, and the reset is held active until the proper voltage level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in “Power and Brown-Out” on page 2105.

5.2.2.6 Software Reset

Software can reset a specific peripheral or generate a reset to the entire microcontroller.

Peripherals can be individually reset by software via peripheral-specific reset registers available beginning at System Control offset 0x500 (for example the **Watchdog Timer Software Reset (SRWD)** register page 367). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset.

The entire microcontroller, including the core, can be reset by software by setting the **SYSRESREQ** bit in the **Application Interrupt and Reset Control (APINT)** register in the core peripheral memory map space. The software-initiated system reset sequence is as follows:

1. A software microcontroller reset is initiated by setting the **SYSRESREQ** bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The core only can be reset by software by setting the **VECTRESET** bit in the **APINT** register. The software-initiated core reset sequence is as follows:

1. A core reset is initiated by setting the **VECTRESET** bit.
2. An internal reset is asserted.
3. The internal reset is deasserted and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 32-12 on page 2112.

5.2.2.7 Watchdog Timer Reset

The Watchdog Timer module's function is to prevent system hangs. The TM4C129XKCZAD microcontroller has two Watchdog Timer modules in case one watchdog clock source fails. One watchdog is run off the system clock and the other is run off the Precision Internal Oscillator (PIOSC).

The watchdog timer can be configured to generate an interrupt or a non-maskable interrupt to the microcontroller on its first time-out and to generate a system reset or power-on reset on its second time-out.

After the watchdog's first time-out event, the 32-bit watchdog counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register and resumes counting down from that value. If the timer counts down to zero again before the first time-out interrupt is cleared, and watchdog reset generation has been enabled through the RESEN bit in the **Watchdog Control Register (WDTCTL)**, the watchdog timer asserts its reset signal to the microcontroller. The reset generated can be a full Power-On Reset or a system reset depending on the value programmed in WDOGn bit field of the **Reset Behavior Control Register (RESBEHAVCTL)**. If the RESEN bit of the **WDTCTL** register is set to 1 and the WDOGn bit field of the **RESBEHAVCTL** register is programmed to 0x3 a full POR is initiated; if WDOGn set to 0x2, then a system reset is issued. When WDOGn is set to a 0x0 or 0x1, then the watchdog time performs its default operation upon assertion, which is issuing a full POR.

The watchdog timer Power-On Reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal POR reset is asserted.
3. The internal reset is released and the core executes a full initialization of the device. Upon completion, the core loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution. Refer to "Reset" on page 2110 for watchdog timeout internal reset deassertion timing.

The watch dog timer system reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal reset is asserted.
3. The internal reset is released and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

For more information on the Watchdog Timer module, see "Watchdog Timers" on page 1173.

The watchdog reset timing is shown in Figure 32-13 on page 2112.

5.2.2.8 Hibernation Module Reset

When the Hibernation module has been configured and powered by an initial "cold" POR and is subsequently put into hibernation mode, a wake event (not including an external reset pin wake) causes the module to generate a system reset. This reset signal resets all circuitry on the device with the exception of the Hibernation module. All Hibernation module registers retain their values after this reset.

When the Hibernation module receives a wake event and V_{DD} is enabled, a system reset sequence occurs as follows:

1. The HIB bit in the **RESC** register is set.
2. An internal reset is asserted.

3. The internal reset is released and the microcontroller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.
4. The **HIBRIS** register in the Hibernation module can be read to determine the cause of the reset.
5. The **HIB** bit in the **RESC** register is cleared by writing a 0.

5.2.2.9 HSSR Reset

The **Hardware System Service Request (HSSR)** register can be used to restore the device back to factory settings. A successful write to the **Hardware System Service Request (HSSR)** register initiates a system reset. The reset initialization process executes before examining the **HSSR** register and processing the command. This register can only be accessed in privileged mode.

Before the return-to-factory settings routine has completed, a system reset sequence executes and the **HSSR** bit in the **RESC** register is set. After the HSSR function has been processed, the **CDOFF** field in the **HSSR** register is written with the outcome of the function processing and another HSSR system reset is executed. The **HSSR** bit can be cleared in the **RESC** register by writing a 0.

For more information regarding use of the **HSSR** register, refer to “Hardware System Service Request” on page 255.

5.2.3 Non-Maskable Interrupt

The microcontroller has multiple sources of non-maskable interrupt (NMI):

- The assertion of the **NMI** signal.
- A main oscillator verification error.
- The **NMISET** bit in the **Interrupt Control and State (INTCTRL)** register in the Cortex™-M4F (see page 177).
- The Watchdog module time-out interrupt when the **INTTYPE** bit in the **Watchdog Control (WDTCTL)** register is set (see page 1179).
- Tamper event (see “Hibernation Module” on page 561 for more information).
- Any of the following BOR trigger events:
 - V_{DDA} under BOR setting
 - V_{DD} under BOR setting

Software must check the cause of the interrupt in the **NMI Cause (NMIC)** register in order to distinguish among the sources.

5.2.3.1 NMI Pin

The NMI signal is an alternate function for the GPIO port pin(s) specified in Table 31-3 on page 2052.

The alternate function must be enabled in the GPIO for the signal to be used as an interrupt, as described in “General-Purpose Input/Outputs (GPIOs)” on page 769. Note that enabling the NMI alternate function requires the use of the GPIO lock and commit function, similar to the requirements of the GPIO port pins associated with JTAG/SWD functionality, see page 813. The active sense of

the NMI signal is High; asserting the enabled NMI signal above V_{IH} initiates the NMI interrupt sequence.

5.2.3.2 Main Oscillator Verification Failure

The TM4C129XKCZAD microcontroller provides a main oscillator verification circuit that generates an error condition if the oscillator is running too fast or too slow. If the main oscillator verification circuit is enabled and a failure occurs, either a power-on reset is generated and control is transferred to the NMI handler, or an interrupt is generated. The MOSCIM bit in the **MOSCCTL** register determines which action occurs. In either case, the system clock source is automatically switched to the PIOSC. If a MOSC failure reset occurs, the NMI handler is used to address the main oscillator verification failure because the necessary code can be removed from the general reset handler, speeding up reset processing. The detection circuit is enabled by setting the CVAL bit in the **Main Oscillator Control (MOSCCTL)** register. The main oscillator verification error is indicated in the main oscillator fail status (MOSCFAIL) bit in the **Reset Cause (RESC)** register. The main oscillator verification circuit action is described in more detail in the section called “Main Oscillator Verification Circuit” on page 247.

5.2.4 Power Control

The TM4C129XKCZAD microcontroller provides an integrated LDO regulator that is used to provide power to the majority of the microcontroller's internal logic. Figure 5-4 shows the power architecture. The voltage output has a maximum voltage of 1.2 V. Refer to “Dynamic Power Management” on page 252 for more information on the LDO operation.

An external LDO may not be used.

Note: VDDA must be supplied with 3.3 V, or the microcontroller does not function properly. VDDA is the supply for all of the analog circuitry on the device, including the clock circuitry.

Figure 5-4. Power Architecture

Note: The V_{DDA} voltage source is typically connected to a filtered voltage source or regulator.

5.2.5 Clock Control

The system control module determines the control of clocks in this part.

5.2.5.1 Fundamental Clock Sources

There are multiple clock sources for use in the microcontroller. The **Run and Sleep Mode Configuration Register (RSCLKCFG)** can be used to configure the required clock source for the device after Power-On Reset, as well as the system clock divisor encodings. The available clock sources are as follows:

- **Precision Internal Oscillator (PIOOSC).** The precision internal oscillator is an on-chip clock source that the microcontroller uses during and following POR. It is the clock source in effect at the start of reset vector fetch and the start of code application execution. It does not require the use of any external components and provides a clock that is $16\text{ MHz} \pm 3\%$ across temperature. The PIOOSC allows for a reduced system cost in applications that require an accurate enough clock source. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference. If the Hibernation Module clock source is a 32.768-kHz oscillator, the precision internal oscillator can be trimmed by software based on a reference clock for increased accuracy. Regardless of whether or not the PIOOSC is the source for the system clock, the PIOOSC can be configured to

be an alternate clock source for some of the peripherals. See the section called “Peripheral Clock Sources” on page 244 for more information on peripherals that can use the PIOSC as an alternate clock.

- **Main Oscillator (MOSC).** The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins. If the PLL is being used, the crystal value can be any frequency between 5 MHz to 25 MHz (inclusive). Refer to Table 5-7 on page 249 for recommended crystal values and PLL register programming. If the PLL is not being used, the crystal may be any one of the supported frequencies between 4 MHz to 25 MHz. The single-ended clock source range is from DC through the specified speed of the microcontroller.
- **Low-Frequency Internal Oscillator (LFIOSC).** The Low-Frequency Internal Oscillator (LFIOSC) provides a nominal frequency of 33 kHz with percentage variance specified in the Electrical Characteristics section. It is intended for use during Deep-Sleep power-saving modes. This power-savings mode provides reduced internal switching and the ability to power down the MOSC and/or PIOSC while in Deep-Sleep mode through configuration of the **Deep Sleep Clock Configuration Register (DSCLKCFG)** register.
- **Hibernation Module RTC Oscillator (RTCOSC) Clock Source.** The Hibernation Module provides a muxed output of two clocks to the System Control Module, an external 32.768-kHz clock or a low-frequency clock (HIB LFIOSC). The Hibernation module has the option of being clocked by a 32.768-kHz oscillator connected to the XOSC0 pin. The 32.768-kHz oscillator can be used for the system clock, thus eliminating the need for an additional crystal or oscillator. Alternatively, the Hibernation module contains a low-frequency oscillator (HIB LFIOSC) which is intended to provide the system with a real-time clock source and may also provide an accurate source of Deep-Sleep or Hibernate mode power savings. Note that the HIB LFIOSC is a different clock source than the LFIOSC. Refer to the Electrical Characteristic Chapter for more information on frequency range.

The internal system clock (SysClk), is derived from any of the above sources. An internal PLL can also be used by the PIOSC or MOSC clock to generate the system clock and peripheral clocks. Table 5-3 on page 241 shows how the various clock sources can be used in a system.

Table 5-3. Clock Source Options

Clock Source	Drive PLL Capability?	PLL Enabled, RSCLKCFG Bit Encodings	SysClk generation capability?	SysClk generation enabled, RSCLKCFG Bit Encodings
Precision Internal Oscillator (PIOSC)	Yes	USEPLL = 1, PLLSRC = 0x0	Yes	USEPLL = 0, OSCSRC = 0x0
Main Oscillator (MOSC)	Yes	USEPLL = 1, PLLSRC = 0x3	Yes	USEPLL = 0, OSCSRC = 0x3
Low Frequency Internal Oscillator (LFIOSC) ^a	No	-	Yes	USEPLL = 0, OSCSRC = 0x2
Hibernation Module RTC Oscillator (RTCOSC). 32.768-kHz Oscillator or HIB LFIOSC	No	-	Yes	USEPLL = 0, OSCSRC = 0x4

a. LFIOSC frequency is characterized as 33 kHz nominal, 10 kHz minimum and 90 kHz maximum.

5.2.5.2 Clock Configuration

The **Run and Sleep Mode Configuration Register (RSCLKCFG)** provides control for the system clock in run and sleep mode. The **Deep Sleep Clock Configuration register (DSCLKCFG)** specifies the behavior of the clock system while in deep sleep mode. These registers control the following clock functionality:

- Source of system clock in run and sleep mode
- Source of system clock in deep-sleep mode
- Enabling/disabling of PLL-derived system clock
- Clock divisors for PLL or oscillator, depending on what is enabled
- Enabling of memory timing parameters for flash

Providing further configuration, the **PLL Frequency n (PLLREQn)** registers allow the PLL VCO frequency (f_{VCO}) to multiplied or divided by programmable values depending on the system clock speed required.

Table 5-4 on page 242 shows the state of the clock sources following a Power-On Reset.

Table 5-4. Clock Source State Following POR

Clock Source	Power-On Reset State
PLL	Disabled/Powered Off
MOSC	Disabled/Powered Off
LFIOSC	Enabled
PIOSC	Enabled
HIB RTCOSC	Disabled

Figure 5-5 shows the logic for the main clock tree. The peripheral blocks are driven by the system clock signal and can be individually enabled/disabled.

Note: The clock sources in Figure 5-5 include a superset of peripherals available in the family. Some peripheral clock sources may not be present on your specific device.

Figure 5-5. Main Clock Tree

Peripheral Clock Sources

In addition to the main clock tree described above, the ADC, USB, Ethernet, PWM, UART, and QSSI all have a Clock Control register in their register map at offset 0xFC8 that can be used to control the clock generation for the module.

ADC Clock Control

The ADC digital block is clocked by the system clock and the ADC analog block is clocked from a separate conversion clock (ADC clock). The ADC clock frequency is 16 MHz and can generate a conversion rate of 1 Msps. There are three sources for the ADC clock:

- The PLL VCO (f_{VCO}) can be used if the CS bit field is 0x0 in the **ADC Clock Configuration (ADCCC)** register and the CLKDIV bit field is configured in the same register.
- The PIOSC can be used directly to provide a conversion rate near 1 Ms/s. To use the PIOSC, the CS field in the **ADCCC** register needs to be set to 0x1 and the ALTCLK field should be programmed to 0x0 in the **Alternate Clock Configuration (ALTCLKCFG)** register.
- The Main Oscillator (MOSC) - The attached crystal must be 16 MHz for a 1 Msps conversion rate.

Note: If the ADC module is not using the PIOSC as the clock source, the system clock must be at least 16 MHz.

USB Clock Control

When the USB module uses the integrated USB PHY, the MOSC must be the clock source, either with or without using the PLL, and the system clock must be at least 30 MHz. In addition, only integer divisors should be used to achieve the 60 MHz USB clock source. Fractional divisors may increase jitter and compromise USB function. The **USB Clock Control Register (USBCC)** register contains a CLKDIV bit field which can be programmed to specify the divisor used to reduce the PLL VCO output to the 60 MHz clock source required for the serialization/deserialization module of the USB controller.

In ULPI mode, if the clock source to the USB is internal, then the `USB0CLK` pin is an output to the external ULPI PHY. If the USB clock source is external then, the `USB0CLK` pin functions as an input from the external ULPI PHY.

Ethernet Clock Control

Available clock sources are dependent on the interface chosen. The following sections describe the clock control for the various interfaces.

The Ethernet Controller Module and Integrated PHY receive two clock inputs. A gated system clock acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC and must be 20 MHz or greater for correct operation. The SYSCLK frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module. See "Ethernet Clock Control" on page 1586 for more information.

PHY Interface Clocking

The Ethernet Controller Module and Integrated PHY receive two clock inputs (see "PHY Interface" on page 1586 for more information):

- A gated system clock acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SysClk frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module.
- The PHY receives the main oscillator (MOSC) which must be $25\text{ MHz} \pm 50\text{ ppm}$ for proper operation. The MOSC source can be a single-ended source or a crystal.

MII Interface Clocking

Four clock inputs are driven into the Ethernet MAC when the MII configuration is enabled. The clocks are described as follows (see “MII Interface” on page 1587 for more information):

- Gated system clock (SysClk): The SysClk signal acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SysClk frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module.
- MOSC: A gated version of the MOSC clock is provided as the Precision Time Protocol (PTP) reference clock (PTPREF_CLK). The MOSC clock source can be a single-ended source on the OSC0 pin or a crystal on the OSC0 and OSC1 pins. When advanced timestamping is used and the Precision Timer Protocol (PTP) module has been enabled by setting the PTPCEN bit in the **EMACCC** register, the MOSC drives PTPREF_CLK. PTPREF_CLK has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. Refer to “IEEE 1588 and Advanced Timestamp Function” on page 1629 for more information.
- EN0RXCK: This clock signal is driven by the external PHY oscillator and is either 2.5 or 25 MHz depending on whether the device is operating at 10 Mbps or 100 Mbps.
- EN0TXCK: This clock signal is driven by the external PHY oscillator and is either 2.5 or 25 MHz depending on whether the device is operating at 10 Mbps or 100 Mbps.

RMII Interface Clocking

There are three clock sources that interface to the Ethernet MAC in an RMII configuration (see “RMII Interface” on page 1588 for more information):

- Gated system clock (SysClk): The SysClk signal acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SysClk frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module.
- MOSC: A gated version of the MOSC clock is provided as the Precision Time Protocol (PTP) reference clock (PTPREF_CLK). The MOSC clock source can be a single-ended source on the OSC0 pin or a crystal on the OSC0 and OSC1 pins. When advanced timestamping is used and the PTP module has been enabled by setting the PTPCEN bit in the **EMACCC** register, the MOSC drives PTPREF_CLK. PTPREF_CLK has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. Refer to “IEEE 1588 and Advanced Timestamp Function” on page 1629 for more information.
- EN0REF_CLK: When using RMII, a 50 MHz external reference clock must drive the EN0REF_CLK input signal and the external PHY. Depending on the configuration of the FES bit in the **Ethernet MAC Configuration (EMACCFG)** register, the reference clock input (EN0REF_CLK) is divided by 20 for 10 Mbps or 2 for 100 Mbps operation and used as the clock for receive and transmit data.

PWM Clock Control

The **PWMCC** register can be used to select the System Clock as the PWM clock source or a divided System Clock. For more information, see page 2007.

Other Peripheral Clock Control

In the UART and QSSI Clock Control Registers, users can choose between the system clock (SysClk), which is the default source for the baud clock, and an alternate clock. Note that there may be special considerations when configuring the baud clock.

Optional Clock Output Signal (DIVSCLK)

An optional clock output, DIVSCLK, is provided which can be used as a clock source to an external device but bears no timing relationship to other signals. Note that this signal is not synchronized to the System Clock. By programming the SRC field in the **Divisor and Source Clock Configuration (DIVSCLK)** register, the following clock outputs may be selected for DIVSCLK:

- System Clock
- PIOSC
- MOSC

The DIV field in the **DIVSCLK** register controls the divided output clock frequency. The DIVSCLK signal is selected as an alternate function of a GPIO signal and has the same inherit electrical characteristics of a GPIO as listed in “Electrical Characteristics” on page 2099.

System Clock Frequency

The system clock (SysClk) is the clock that is distributed to the processor and the integrated peripherals after clock gating. The SysClk frequency is based on the frequency of the clock source and the divisor factor. For example, if the PLL is not being used and the device is not in deep sleep mode, then the OSYSDIV bit field in the **RSCLKCFG** register is the divisor used to determine the system clock. If the PLL is being used, then PSYSDIV bit field in the **RSCLKCFG** register must be programmed as well as the values in the **PLLREQ0** and **PLLREQ1** registers. If the device is in deep sleep mode, then the **Deep Sleep Clock Configuration Register (DSCLKCFG)** can be programmed with the divisor bit field DSSYSYDIV to modify the clock source frequency. Table 5-5 on page 246 shows the different system clock frequency calculations based on the operation mode, clock source and PLL encoding.

Table 5-5. System Clock Frequency

Clock Mode	USEPLL (RSCLKCFG)	SYCLK Value	Divisor Factors Used
Run or Sleep	1	$f_{VCO} / (\text{PSYSDIV} + 1)$	PSYSDIV bit field in RSCLKCFG ; MINT, MDIV in PLLREQ0 ; Q, N bits in PLLREQ1
Run or Sleep	0	$f_{OSCCLK} / (\text{OSYSDIV} + 1)$	OSYSDIV bit field in RSCLKCFG
Deep Sleep	PLL not enabled in Deep Sleep	$f_{OSCCLK} / (\text{DSSYSYDIV} + 1)$	DSSYSYDIV bit field in DSCLKCFG

5.2.5.3 Precision Internal Oscillator Operation (PIOSC)

The microcontroller powers up with the PIOSC running. If another clock source is desired, the PIOSC must remain enabled because it is used for internal functions. The PIOSC can only be disabled during Deep-Sleep mode. It can be powered down by setting the PIOSCPD bit in the **DSCLKCFG** register.

The PIOSC generates a 16-MHz clock with a $\pm 3\%$ accuracy. At the factory, the PIOSC is set to 16 MHz at room temperature, however, the frequency can be trimmed for other voltage or temperature conditions using software in the following ways:

- Default calibration: clear the UTEN bit and set the UPDATE bit in the **Precision Internal Oscillator Calibration (PIOSCCAL)** register.
- User-defined calibration: The user can program the UT value to adjust the PIOSC frequency. As the UT value increases, the generated period increases. To commit a new UT value, first set the UTEN bit, then program the UT field, and then set the UPDATE bit. The adjustment finishes within a few clock periods and is glitch free.
- Automatic calibration using the enable 32.768-kHz oscillator from the Hibernation module: Set the CAL bit in the **PIOSCCAL** register; the results of the calibration are shown in the RESULT field in the **Precision Internal Oscillator Statistic (PIOSCSTAT)** register. After calibration is complete, the PIOSC is trimmed using the trimmed value returned in the CT field.

5.2.5.4 Main Oscillator (MOSC)

The main oscillator supports the use of crystals from 5 to 25 MHz. The system control's **RSCLKCFG** register can be configured to specify the MOSC as the system clock or as the PLL input source. The MOSC can be selected as the oscillator source by programming the OSCRC bit in the **RSCLKCFG** register. The NOXTAL bit in the **MOSCCTL** register allows the user to turn off power to the MOSC if no crystal is connected reducing power draw from the MOSC circuit.

Main Oscillator Verification Circuit

The clock control includes circuitry to ensure that the main oscillator is running at the appropriate frequency. The circuit monitors the main oscillator frequency and signals if the frequency is outside of the allowable band of attached crystals.

The detection circuit is enabled using the CVAL bit in the **Main Oscillator Control (MOSCCTL)** register. If this circuit is enabled and detects an error, and if the MOSCIM bit in the **MOSCCTL** register is clear, then the following sequence is performed by the hardware:

1. The MOSCFAIL bit in the **Reset Cause (RESC)** register is set.
2. The system clock is switched from the main oscillator to the PIOSC.
3. An internal system reset is initiated.
4. Reset is deasserted and the processor is directed to the NMI handler during the reset sequence.

5.2.5.5 PLL

The PLL has two modes of operation: Normal and Power-Down

- Normal: The PLL oscillates based on the values in the **PLLREQ0** and **PLLREQ1** registers and drives the output.
- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the **PLLPWR** bit in the **PLLREQ0** register (see page 303).

PLL Configuration

The PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the PLL to drive the output. The PLL is controlled using the **PLLREQ0**, **PLLREQ1** and **PLLSTAT** registers. Changes made to these registers do not become active until after the **NEWFREQ** bit in the **RSCLKCFG** register is enabled.

The clock source for the main PLL is selected by configuring the **PLLSRC** field in the **Run and Sleep Clock Configuration (RSCLKCFG)** register.

The PLL allows for the generation of system clock frequencies in excess of the reference clock provided. The reference clocks for the PLL are the PIOSC and the MOSC. The PLL is controlled by two registers, **PLLREQ0** and **PLLREQ1**. The PLL VCO frequency (f_{VCO}) is determined through the following calculation:

$$f_{VCO} = f_{IN} * MDIV$$

where

$$f_{IN} = f_{XTAL}/(Q+1)(N+1) \text{ or } f_{PIOSC}/(Q+1)(N+1)$$

$$MDIV = MINT + (MFRAC / 1024)$$

The **Q** and **N** values are programmed in the **PLLREQ1** register. Note that to reduce jitter, MFRAC should be programmed to 0x0.

When the PLL is active, the system clock frequency (SysClk) is calculated using the following equation:

$$\text{SysClk} = f_{VCO} / (\text{PSYSDIV} + 1)$$

The PLL system divisor factor (PSYSDIV) determines the value of the system clock. Table 5-6 on page 248 shows how the system divisor encodings affect the system clock frequency when the $f_{VCO} = 480$ MHz.

Table 5-6. System Divisor Factors for $f_{VCO}=480$ MHz

System Clock (SYSCLK) (MHz)	f_{VCO} (MHz)= 480 MHz
	System Divisors (PSYSDIV +1) ^a
120	4
60	8
48	10
30	16
24	20
12	40
6	80

a. The use of non-integer divisors introduce additional jitter which may affect interface performance.

If the main oscillator provides the clock reference to the PLL, the translation provided by hardware and used to program the PLL is available for software in the **PLL Frequency n (PLLREQn)** registers (see page 303). The internal translation provides a translation within $\pm 1\%$ of the targeted PLL VCO frequency. Table 5-7 on page 249 shows the actual PLL frequency and error for a given crystal choice.

Table 5-7 on page 249 provides examples of the programming expected for the **PLLREQ0** and **PLLREQ1** registers. The first column specifies the input crystal frequency and the last column displays the PLL frequency given the values of MINT and N, when Q=0.

Table 5-7. Actual PLL Frequency^a

Crystal Frequency (MHz)	MINT (Decimal Value)	MINT (Hexadecimal Value)	N	Reference Frequency (MHz) ^b	PLL Frequency (MHz)
5	64	0x40	0x0	5	320
6	160	0x35	0x2	2	320
8	40	0x28	0x0	8	320
10	32	0x20	0x0	10	320
12	80	0x50	0x2	4	320
16	20	0x14	0x0	16	320
18	160	0xA0	0x8	2	320
20	16	0x10	0x0	20	320
24	40	0x28	0x2	8	320
25	64	0x40	0x4	5	320
5	96	0x60	0x0	5	480
6	80	0x50	0x0	6	480
8	60	0x3C	0x0	8	480
10	48	0x30	0x0	10	480
12	40	0x28	0x0	12	480
16	30	0x1E	0x0	16	480
18	80	0x50	0x2	6	480
20	24	0x18	0x0	20	480
24	20	0x14	0x0	24	480
25	96	0x60	0x4	5	480

a. For all examples listed, Q=0

b. For a given crystal frequency, N should be chosen such that the reference frequency is within 4 to 30 MHz.

PLL Operation

If a PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is T_{READY} (see Table 32-16 on page 2113). During the relock time, the affected PLL is not usable as a clock reference. Software can poll the LOCK bit in the **PLL Status (PLLSTAT)** register to determine when the PLL has locked.

Modification of the PLL VCO frequency may not be performed while the PLL serves as a clock source to the system. All changes to the PLL must be performed using a different clock source until the PLL has locked frequency. Thus, changing the PLL VCO frequency must be done as a sequence from PLL to PIOSC/MOSC and then PIOSC/MOSC to new PLL.

Hardware is provided to keep the PLL from being used as a system clock until the T_{READY} condition is met after one of the two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RSCLKCFG** register is re-programmed to enable the PLL. Software can use many methods to ensure that the system is clocked from the PLL, including periodically polling the **PLLLRIS** bit in the **Raw Interrupt Status (RIS)** register at offset 0x050, and enabling the PLL Lock interrupt in the **Interrupt Mask Control (IMC)** register at offset 0x054.

5.2.6 System Control

There are four levels of operation for the microcontroller defined as:

- Run mode
- Sleep mode
- Deep-Sleep mode
- Hibernation mode

For power-savings purposes, the peripheral-specific **RCGCx**, **SCGCx**, and **DCGCx** registers (for example, **RCGCWD**) control the clock-gating logic for that peripheral or block in the system while the microcontroller is in Run, Sleep, and Deep-Sleep mode, respectively. These registers are located in the System Control register map starting at offsets 0x600, 0x700, and 0x800, respectively.

Note: A change in the **RCGCx** (or **SCGCx/DCGCx/PCx/SRx**) registers may not have an immediate effect on the clock in all situations. It is recommended that software poll the peripheral's **Peripheral Ready (PRx)** register to determine when a peripheral is ready to be accessed.

Note: If a peripheral is configured to be clock-gated during Run, Sleep- or Deep-Sleep mode, then software should ensure that there are no pending transfers or register accesses before or immediately after entering the clock-gated mode.

The following sections describe the different modes in detail.

5.2.6.1 Run Mode

In Run mode, the microcontroller actively executes code. Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the peripheral-specific **RCGC** registers. In run mode (and in sleep mode), the **Run and Sleep Clock Configuration (RSCLKCFG)** register specifies the source of SysClk. The source is either from the VCO output of the PLL divided down by a dedicated divisor (divisor value specified by the **PSYSDIV** field) or from the output of an oscillator divided down by a dedicated divisor (divisor value specified by the **OSYSDIV** field). The source is selected using the **USEPLL** bit in the **RSCLKCFG** register. The PLL has two sources of reference clock as an input: the main oscillator (MOSC) or the precision internal oscillator (PIOOSC). The PLL input select is specified by **PLLSRC**. If the PLL VCO output is not selected as the source of SysClk then the following reference clocks can be programmed as an input:

- Main Oscillator (MOSC)
- Precision Internal Oscillator (PIOOSC)
- Low-Frequency Internal Oscillator (LFIOSC)
- Hibernation Module Real-Time Oscillator Source (RTCOSC): The source of this signal can be either a 32.768-kHz oscillator source, an external 32.768-kHz clock source or the internal Hibernation Module Low-Frequency Oscillator (HIBLFIOSC). If this clock source is selected, it has to be enabled in the Hibernation Module as well.

The selection of these alternate sources is through the **OSCSRC** field in the **RSCLKCFG** register.

5.2.6.2 Sleep Mode

In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor and the memory subsystem are not clocked and therefore no longer execute code. Sleep mode is entered

by the Cortex-M4F core executing a **WFI** (Wait for Interrupt) instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 136 for more details.

Peripherals are clocked that are enabled in the peripheral-specific **SCGC** registers when auto-clock gating is enabled or the peripheral-specific **RCGC** registers when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.

The option to use the PLL VCO or an alternate oscillator source such as MOSC, PIOSC, Hibernation Module real time clock, or the LFIOSC is the same as described in Run Mode. The **RSCLKCFG** register programming applies to Sleep Mode.

Additional sleep modes are available that lower the power consumption of the SRAM and Flash memory. However, the lower power consumption modes have slower sleep and wake-up times.

Caution – If the Cortex-M4F Debug Access Port (DAP) has been enabled, and the device wakes from a low power sleep or deep-sleep mode, the core may start executing code before all clocks to peripherals have been restored to their Run mode configuration. The DAP is usually enabled by software tools accessing the JTAG or SWD interface when debugging or flash programming. If this condition occurs, a Hard Fault is triggered when software accesses a peripheral with an invalid clock.

A software delay loop can be used at the beginning of the interrupt routine that is used to wake up a system from a **WFI** (Wait For Interrupt) instruction. This stalls the execution of any code that accesses a peripheral register that might cause a fault. This loop can be removed for production software as the DAP is most likely not enabled during normal execution.

Because the DAP is disabled by default (power on reset), the user can also power cycle the device. The DAP is not enabled unless it is enabled through the JTAG or SWD interface.

5.2.6.3 Deep-Sleep Mode

In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Deep-Sleep mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the microcontroller to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Deep-Sleep mode is entered by first setting the **SLEEPDEEP** bit in the **System Control (SYSCTRL)** register (see page 183) and then executing a **WFI** instruction. Any properly configured interrupt event in the system brings the processor back into Run mode. See “Power Management” on page 136 for more details.

The Cortex-M4F processor core and the memory subsystem are not clocked in Deep-Sleep mode. Peripherals are clocked that are enabled in the peripheral-specific **DCGC** registers when auto-clock gating is enabled or the peripheral-specific **RCGC** registers when auto-clock gating is disabled. The system clock source is specified in the **DSCLKCFG** register. When the **DSCLKCFG** register is used, the internal oscillator source is powered up, if necessary, and other clocks are powered down. If the PLL is running at the time of the **WFI** instruction, hardware shuts down the PLL for power savings. For further power savings the PIOSC can be disabled through the **PIOSCPD** bit in the **DSCLKCFG** register. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration. If the PIOSC is used as the PLL reference clock source, it may continue to provide the clock during Deep-Sleep. See page 292.

Note: If the MOSC is chosen as the Deep-Sleep clock source in the **DSCLKCFG** register, the MOSC must also be configured as the Run and Sleep clock source in the **RSCLKCFG** register prior to entering Deep Sleep. If the PIOSC, LFIOSC, or Hibernation RTC Module Oscillator (HIBLFIOSC or 32-kHz crystal) is configured as the Run and Sleep clock source

in the **RSCLKFCFG** register, and the MOSC is configured as the Deep-Sleep clock source in the **DSCLKCFG** register, then two outcomes are possible:

- If the PIOSC is still powered in Deep Sleep (using the **PIOSCPD** bit in the **DSCLKCFG** register) then the PIOSC is utilized as the clock source when entering Deep Sleep and the device enters and exits the Deep-Sleep state normally. The MOSC is not used as the clock source in Deep Sleep.
- If the PIOSC has been configured to be powered down in Deep Sleep, then the device can enter the Deep-Sleep state, but cannot exit properly. This situation can be avoided by programming the MOSC as the Run and Sleep clock source in the **RSCLKCFG** register prior to entering Deep Sleep.

To provide the lowest possible Deep-Sleep power consumption as well the ability to wake the processor from a peripheral without reconfiguring the peripheral for a change in clock, some of the communications modules have a Clock Control register at offset 0xFC8 in the module register space. The CS field in the Clock Control register allows the user to select the PIOSC or ALTCLK as the clock source for the module's baud clock. When the microcontroller enters Deep-Sleep mode, the PIOSC or ALTCLK becomes the source for the module clock as well, which allows the transmit and receive FIFOs to continue operation while the part is in Deep-Sleep. Figure 5-6 on page 252 shows how the clocks are selected.

Figure 5-6. Module Clock Selection

Additional power management modes are available that lower the power consumption of the peripheral memory, Flash, and SRAM memory. However, the lower power consumption modes have slower deep-sleep and wake-up times.

5.2.6.4 Dynamic Power Management

In addition to the Sleep and Deep-Sleep modes and the clock gating for the on-chip modules, there are several additional power mode options that allow the LDO, Flash memory, and SRAM into

different levels of power savings while in Sleep or Deep-Sleep modes. In addition, software has the ability to control the LDO settings to gain a power advantage when running at slower speeds. Note that these features may not be available on all devices; the **System Properties (SYSPROP)** register provides information on whether a mode is supported on a given MCU. The following registers provide these capabilities:

- **Peripheral Power Control (PCx):** Controls power to peripheral if that peripheral has the ability to respond to a power request.
- **Peripheral Memory Power Control (xMPC):** Provides power control to some the peripheral memory arrays.
- **LDO Sleep Power Control (LDOSPCTL):** Controls the LDO value in Sleep mode
- **LDO Deep-Sleep Power Control (LDODPCTL):** Controls the LDO value in Deep-Sleep mode
- **LDO Sleep Power Calibration (LDOSPCAL):** Provides factory recommendations for the LDO value in Sleep mode
- **LDO Deep-Sleep Power Calibration (LDODPCAL):** Provides factory recommendations for the LDO value in Deep-Sleep mode
- **Sleep Power Configuration (SLPPWRCFG):** Controls the power saving modes for Flash memory and SRAM in Sleep mode
- **Deep-Sleep Power Configuration (DSLPPWRCFG):** Controls the power saving modes for Flash memory and SRAM in Deep-Sleep mode
- **Deep-Sleep Clock Configuration (DSCLKCFG):** Controls the clocking in Deep-Sleep mode
- **Sleep / Deep-Sleep Power Mode Status (SDPMST):** Provides status information on the various power saving events

Peripheral Power Control

The **Peripheral Power Control (PCx)** registers reside at offset 0x900 in the System Control module register space. For modules that reside in a separate power domain, the user has the capability to power down the module by setting the appropriate `Pn` bit to 0x0. This configuration provides the lowest power consumption state of the module. Currently the following registers can be programmed to disable power to the module:

- **PCCAN** register
- **PCLCD** register
- **PCEMAC** register
- **PCEPHY** register
- **PCUSB** register
- **PCCCM** register

Modification to other PCx registers have no effect, since they are not on their own power domain.

Peripheral Memory Power Control

When Deep-Sleep is entered, users have the capability to reduce power further in peripheral modules which have their own associated memory array. Many of these peripherals can be programmed to enable a low-power retention mode or a power down of their associated peripheral SRAM array. If retention is supported and the PWRCTL bit field of the module's **xMPC** register is programmed to 0x1, the associated peripheral SRAM memory array is put in retention mode in which no accesses can be performed. When the PWRCTL bit is set to 0x0 in Deep-Sleep mode, the memory is powered off, the contents are lost and the SRAM is not accessible. The peripheral's **Power Domain Status (xPDS)** can be read to determine the status of the peripheral's memory array as well as the peripheral's current power domain status. The table below lists the capabilities of peripherals with SRAM arrays during low power modes.

Table 5-8. Peripheral Memory Power Control

Module	Memory Retention Capability?	Memory Array Power Down Capability?
USB	Yes	Yes
EMAC	No	Yes (only when power domain is off, PCEMAC register = 0x0)
LCD	No	No
CAN	No	Yes

LDO Power Control

Note: While the device is connected through JTAG, the LDO control settings for Sleep or Deep-Sleep are not available and will not be applied.

Software can configure the **LDOSPCTL** register (see page 311) and/or the **LDODPCTL** register (see page 314) to dynamically raise or lower the LDO voltage in Sleep and Deep-Sleep mode depending on whether an increase in performance or reduction in power consumption is required. The **VLDO** field in the **LDOSPCTL** register is set to 1.2 V as default. The **LDODPCTL** register is set to an LDO voltage of 0.9 V as default. If an application requires performance over power consumption in Deep-Sleep, the Deep-Sleep LDO voltage can be configured to a higher voltage than 0.9 V during System Control initialization by setting the **VADJEN** bit and programming the **VLDO** field of the **LDODPCTL** register.

Before the LDO level is lowered in Sleep or Deep-Sleep, the system clock must be configured to an acceptable frequency in the **RSCLKCFG** register for Sleep mode and in **DSLPCLKCFG** for Deep-Sleep mode. The following table shows the maximum System Clock and PIOSC frequency with respect to the LDO voltage.

Table 5-9. Maximum System Clock and PIOSC Frequency with Respect to LDO Voltage

Operating Voltage (LDO)	Maximum System Clock Frequency	PIOSC
1.2	120 MHz	16 MHz
0.9	30 MHz	16 MHz

The LDO Power Calibration registers, **LDOSPCAL** and **LDODPCAL**, provide suggested values for the LDO in the various modes. If software requests an LDO value that is too low or too high, the value is not accepted and an error is reported in the **SDPMST** register.

Note: When using the USB module, the LDO must be configured to 1.2 V.

Flash Memory and SRAM Power Control

During Sleep or Deep-Sleep mode, Flash memory can be in either the default active mode or the low power mode; SRAM can be in the default active mode, standby mode, or low power mode. The active mode in each case provides the fastest times to sleep and wake up, but consumes more power. Low power mode provides the lowest power consumption, but takes longer to sleep and wake up.

The SRAM can be programmed to prohibit any power management by configuring the **SRAMPM** bit in the **Sleep Power Configuration (SLPPWRCFG)** register. This configuration operates in the same way that legacy Stellaris® devices operate and provides the fastest sleep and wake-up times, but consumes the most power while in Sleep and Deep-Sleep mode.

The following power saving options are available in Sleep and Deep-Sleep modes:

- The clocks can be gated according to the settings in the peripheral-specific **SCGC** or **DCGC** registers.
- In Deep-Sleep mode, the clock source can be changed and the PIOSC can be powered off (if no active peripheral requires it) using the **DSCLKCFG** register. These options are not available for Sleep mode.
- The LDO voltage can be changed using the **LDOSPCTL** or **LDODPCTL** register.
- The Flash memory can be put into low power mode.
- The SRAM can be put into standby or low power mode.

For typical power consumption and sleep/wake-up times, refer to “Current Consumption” on page 2171 and “Sleep Modes” on page 2120.

The **SDPMST** register provides results on the Dynamic Power Management command issued. It also has some real time status that can be viewed by a debugger or the core if it is running. These events do not trigger an interrupt and are meant to provide information to help tune software for power management. The status register gets written at the beginning of every Dynamic Power Management event request that provides error checking. There is no mechanism to clear the bits; they are overwritten on the next event. The data is real time and there is no event to register that information.

5.2.6.5 Hibernation Mode

In this mode, the power supplies are turned off to the main part of the microcontroller and only the Hibernation module's circuitry is active. An external wake event or RTC event is required to bring the microcontroller back to Run mode. The Cortex-M4F processor and peripherals outside of the Hibernation module see a normal "power on" sequence and the processor starts running code. Software can determine if the microcontroller has been restarted from Hibernate mode by inspecting the **HIB** bit in the **RESC** register. If the HIB module has been put in hibernation mode and a reset occurs, the reset handler should check the **HIB Raw Interrupt Status (HIBRIS)** register in the HIB module to determine the cause of the reset.

5.2.6.6 Hardware System Service Request

The **Hardware System Service Request (HSSR)** register is used to issue a request that returns a device to factory settings. An HSSR consists of writing the appropriate key and data structure address offset to the **HSSR** register in the System Control Module. Any HSSR initiates a reset event as the first event in the process. Then the **HSSR** register is evaluated.

To write to the **HSSR** register the **KEY** field must be set to 0xCA. The **CDOFF** field in the **HSSR** register can have one of the following three values:

- 0x00.0000 – No request and/or the previous request completed successfully
- 0xFF.FFFF – No request and the previous request failed
- Anything else – The offset into SRAM of a HSSR request structure

During the HSSR routine, if anything else is seen in the **CDOFF** field, then the offset is examined for validity and the structure it points to is examined for validity. If either is invalid, the request has failed and 0xFF.FFFF is written to the **CDOFF** field.

The offset is valid if all the following conditions are met:

- The **CDOFF** value is word aligned (that is, the two LSBs are both zero)
- The **CDOFF** value is at least 0x2000.4000
- The **CDOFF** value is at most 0x2003.FFF0

Once a valid HSSR offset is determined, the following structure is examined in the SRAM that is indicated by the **CDOFF** field in the **HSSR** register. In order to initiate a return-to-factory settings function, the data structure must be as follows:

- Request (32 bits) = 0xFEED.0001
- Data 1 (32 bits) = 0x0201.0100
- Data 2 (32 bits) = 0x0D08.0503
- Data 3 (32 bits) = 0x5937.2215

If the data bytes are correct, then the device is returned to factory condition. During the return-to-factory settings function, the following events occur:

- The RAM is erased in the Hibernation module
- The system SRAM is erased
- The **FMPPEn** registers are set to 0xFFFF.FFFF (to allow a Flash erase operation to occur)
- The EEPROM pages are erased
- A mass-erase of the flash array occurs
- The **BOOTCFG** register is written with 0xFFFF.FFFE

Once the return-to-factory settings sequence is completed, the **CDOFF** field of the **HSSR** register is written with 0x00.0000, indicating a successful completion and activating a system reset.

5.3 Initialization and Configuration

The PLL is configured using direct register writes to the **PLLREQn**, **MEMTIM0**, and **PLLSTAT** registers. The steps for initializing the system clock from POR to use the PLL from the main oscillator is as follows:

1. Once POR has completed, the PIOSC is acting as the system clock.
2. Power up the MOSC by clearing the NOXTAL bit in the **MOSCCTL** register.
3. If single-ended MOSC mode is required, the MOSC is ready to use. If crystal mode is required, clear the PWRDN bit and wait for the MOSCPUPRIS bit to be set in the **Raw Interrupt Status (RIS)**, indicating MOSC crystal mode is ready.
4. Set the OSCSRC field to 0x3 in the **RSCLKCFG** register at offset 0x0B0.
5. If the application also requires the MOSC to be the deep-sleep clock source, then program the DSOSCSRC field in the **DSCLKCFG** register to 0x3.
6. Write the **PLLREQ0** and **PLLREQ1** registers with the values of Q, N, MINT, and MFRAC to configure the desired VCO frequency setting.
7. Write the **MEMTIM0** register to correspond to the new system clock setting.
8. Wait for the **PLLSTAT** register to indicate the PLL has reached lock at the new operating point (or that a timeout period has passed and lock has failed, in which case an error condition exists and this sequence is abandoned and error processing is initiated).
9. Write the **RSCLKCFG** register's PSYSDIV value, set the USEPLL bit to enabled, and MEMTIMU bit.

If it is necessary to keep the MOSC powered on during automatic (deep-sleep) or accidental power down, then the MOSCDPD bit should be set to 0x1. Otherwise, if the MOSCDPD bit is set to 0x0, the MOSC is powered off when deep-sleep is entered or automatic power down occurs. The following table describes the relationship between the PWRDN bit in the **MOSCCTL** register and the MOSCDPD bit in the **DSCLKCFG** register:

Table 5-10. MOSC Configurations

PWRDN bit	MOSCDPD field	Result
0	0	MOSC is powered ON in run and sleep modes, but is disabled in accidental power down, when the PWRDN bit is set in the MOSCCTL register, or in deep-sleep mode only if it is not the deep-sleep clock source (DSOSCSRC != 0x3).
0	1	MOSC is powered and running in run, sleep and deep-sleep modes.
1	0	MOSC is powered off, and does not run in any mode. Please note, that in this configuration, when the MOSC is disabled, the MOSC must not be chosen as a clock source or indeterminate results occur.
1	1	MOSC runs and does not disable itself in run, sleep, and deep-sleep modes regardless of the fact that the PWRDN bit is set.

Note: The MOSCDPD bit has an effect in all modes of operation

To change the system clock frequency by changing its corresponding PSYSDIV or OSYSDIV value, a user must ensure timing parameters to memory are within range through the following steps:

1. If the change in system clock frequency changes the operational range of the timing parameters, the **MEMTIM0** register must be updated. If so, write the timing configuration register, **MEMTIM0**, setting the value to correspond to the final SYSCLK frequency ($f_{VCO}/\text{new SYSDIV}$ or f_{osc}). Otherwise the **MEMTIM0** register should not be changed.

2. Write the **RSCLKCFG** register's PSYSDIV value and MEMTIMU bit if the **MEMTIM0** register is updated in the first step. The new SYSDIV is now in effect.

5.4 Register Map

Table 5-11 on page 258 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register's address, relative to the System Control base address of 0x400F.E000.

Note: Spaces in the System Control register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Additional Flash and ROM registers defined in the System Control register space are described in the “Internal Memory” on page 630.

5.5 System Control Register Descriptions (System Control Offset)

All addresses given are relative to the System Control base address of 0x400F.E000.

Register 1: Device Identification 0 (DID0), offset 0x000

This register identifies the version of the microcontroller. Each microcontroller is uniquely identified by the combined values of the **CLASS** field in the **DID0** register and the **PARTNO** field in the **DID1** register. The **MAJOR** and **MINOR** bit fields indicate the die revision number. Combined, the **MAJOR** and **MINOR** bit fields indicate the part revision number.

MAJOR Bitfield Value	MINOR Bitfield Value	Die Revision	Part Revision
0x0	0x0	A0	1
0x0	0x1	A1	2

Device Identification 0 (DID0)

Base 0x400F.E000

Offset 0x000

Type RO, reset -

Bit/Field	Name	Type	Reset	Description				
31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
30:28	VER	RO	0x1	<p>DID0 Version</p> <p>This field defines the DID0 register format version. The version number is numeric. The value of the VER field is encoded as follows (all other encodings are reserved):</p> <table border="0"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0x1</td> <td>Second version of the DID0 register format.</td> </tr> </table>	Value	Description	0x1	Second version of the DID0 register format.
Value	Description							
0x1	Second version of the DID0 register format.							
27:24	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
23:16	CLASS	RO	0x0A	<p>Device Class</p> <p>The CLASS field value identifies the internal design from which all mask sets are generated for all microcontrollers in a particular product line. The CLASS field value is changed for new product lines, for changes in fab process (for example, a remap or shrink), or any case where the MAJOR or MINOR fields require differentiation from prior microcontrollers. The value of the CLASS field is encoded as follows (all other encodings are reserved):</p> <table border="0"> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0x0A</td> <td>Tiva™ Snowflake-class microcontrollers</td> </tr> </table>	Value	Description	0x0A	Tiva™ Snowflake-class microcontrollers
Value	Description							
0x0A	Tiva™ Snowflake-class microcontrollers							

Bit/Field	Name	Type	Reset	Description								
15:8	MAJOR	RO	-	<p>Major Revision</p> <p>This field specifies the major revision number of the microcontroller. The major revision reflects changes to base layers of the design. The major revision number is indicated in the part number as a letter (A for first revision, B for second, and so on). This field is encoded as follows:</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Revision A (initial device)</td></tr> <tr> <td>0x1</td><td>Revision B (first base layer revision)</td></tr> <tr> <td>0x2</td><td>Revision C (second base layer revision)</td></tr> </tbody> </table> <p>and so on.</p>	Value	Description	0x0	Revision A (initial device)	0x1	Revision B (first base layer revision)	0x2	Revision C (second base layer revision)
Value	Description											
0x0	Revision A (initial device)											
0x1	Revision B (first base layer revision)											
0x2	Revision C (second base layer revision)											
7:0	MINOR	RO	-	<p>Minor Revision</p> <p>This field specifies the minor revision number of the microcontroller. The minor revision reflects changes to the metal layers of the design. The MINOR field value is reset when the MAJOR field is changed. This field is numeric and is encoded as follows:</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Initial device, or a major revision update.</td></tr> <tr> <td>0x1</td><td>First metal layer change.</td></tr> <tr> <td>0x2</td><td>Second metal layer change.</td></tr> </tbody> </table> <p>and so on.</p>	Value	Description	0x0	Initial device, or a major revision update.	0x1	First metal layer change.	0x2	Second metal layer change.
Value	Description											
0x0	Initial device, or a major revision update.											
0x1	First metal layer change.											
0x2	Second metal layer change.											

Register 2: Device Identification 1 (DID1), offset 0x004

This register identifies the device family, part number, temperature range, pin count, and package type. Each microcontroller is uniquely identified by the combined values of the **CLASS** field in the **DID0** register and the **PARTNO** field in the **DID1** register.

Device Identification 1 (DID1)

Base 0x400F.E000

Offset 0x004

Type RO, reset -

Bit/Field	Name	Type	Reset	Description						
31:28	VER	RO	0x1	<p>DID1 Version</p> <p>This field defines the DID1 register format version. The version number is numeric. The value of the VER field is encoded as follows (all other encodings are reserved):</p> <table> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Initial DID1 register format definition, indicating a Stellaris LM3Snnn device.</td> </tr> <tr> <td>0x1</td> <td>Second version of the DID1 register format.</td> </tr> </tbody> </table>	Value	Description	0x0	Initial DID1 register format definition, indicating a Stellaris LM3Snnn device.	0x1	Second version of the DID1 register format.
Value	Description									
0x0	Initial DID1 register format definition, indicating a Stellaris LM3Snnn device.									
0x1	Second version of the DID1 register format.									
27:24	FAM	RO	0x0	<p>Family</p> <p>This field provides the family identification of the device within the Tiva™ product portfolio. The value is encoded as follows (all other encodings are reserved):</p> <table> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Tiva™ C Series microcontrollers and legacy Stellaris microcontrollers, that is, all devices with external part numbers starting with TM4Cor LM3S.</td> </tr> </tbody> </table>	Value	Description	0x0	Tiva™ C Series microcontrollers and legacy Stellaris microcontrollers, that is, all devices with external part numbers starting with TM4Cor LM3S.		
Value	Description									
0x0	Tiva™ C Series microcontrollers and legacy Stellaris microcontrollers, that is, all devices with external part numbers starting with TM4Cor LM3S.									
23:16	PARTNO	RO	0x37	<p>Part Number</p> <p>This field provides the part number of the device within the family. This value indicates the TM4C129XKCZAD microcontroller.</p>						

Bit/Field	Name	Type	Reset	Description																		
15:13	PINCOUNT	RO	0x7	<p>Package Pin Count</p> <p>This field specifies the number of pins on the device package. The value is encoded as follows (all other encodings are reserved):</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>reserved</td></tr> <tr> <td>0x1</td><td>reserved</td></tr> <tr> <td>0x2</td><td>100-pin LQFP package</td></tr> <tr> <td>0x3</td><td>64-pin LQFP package</td></tr> <tr> <td>0x4</td><td>144-pin LQFP package</td></tr> <tr> <td>0x5</td><td>157-pin BGA package</td></tr> <tr> <td>0x6</td><td>128-pin TQFP package</td></tr> <tr> <td>0x7</td><td>212-pin BGA package</td></tr> </tbody> </table>	Value	Description	0x0	reserved	0x1	reserved	0x2	100-pin LQFP package	0x3	64-pin LQFP package	0x4	144-pin LQFP package	0x5	157-pin BGA package	0x6	128-pin TQFP package	0x7	212-pin BGA package
Value	Description																					
0x0	reserved																					
0x1	reserved																					
0x2	100-pin LQFP package																					
0x3	64-pin LQFP package																					
0x4	144-pin LQFP package																					
0x5	157-pin BGA package																					
0x6	128-pin TQFP package																					
0x7	212-pin BGA package																					
12:8	reserved	RO	0x0	<p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>																		
7:5	TEMP	RO	0x3	<p>Temperature Range</p> <p>This field specifies the temperature rating of the device. The value is encoded as follows (all other encodings are reserved):</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Commercial temperature range</td></tr> <tr> <td>0x1</td><td>Industrial temperature range</td></tr> <tr> <td>0x2</td><td>Extended temperature range</td></tr> </tbody> </table>	Value	Description	0x0	Commercial temperature range	0x1	Industrial temperature range	0x2	Extended temperature range										
Value	Description																					
0x0	Commercial temperature range																					
0x1	Industrial temperature range																					
0x2	Extended temperature range																					
4:3	PKG	RO	0x2	<p>Package Type</p> <p>This field specifies the package type. The value is encoded as follows (all other encodings are reserved):</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>reserved</td></tr> <tr> <td>0x1</td><td>QFP package</td></tr> <tr> <td>0x2</td><td>BGA package</td></tr> </tbody> </table>	Value	Description	0x0	reserved	0x1	QFP package	0x2	BGA package										
Value	Description																					
0x0	reserved																					
0x1	QFP package																					
0x2	BGA package																					
2	ROHS	RO	0x1	<p>RoHS-Compliance</p> <p>This bit specifies whether the device is RoHS-compliant. A 1 indicates the part is RoHS-compliant.</p>																		
1:0	QUAL	RO	-	<p>Qualification Status</p> <p>This field specifies the qualification status of the device. The value is encoded as follows (all other encodings are reserved):</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Engineering Sample (unqualified)</td></tr> <tr> <td>0x1</td><td>Pilot Production (unqualified)</td></tr> <tr> <td>0x2</td><td>Fully Qualified</td></tr> </tbody> </table>	Value	Description	0x0	Engineering Sample (unqualified)	0x1	Pilot Production (unqualified)	0x2	Fully Qualified										
Value	Description																					
0x0	Engineering Sample (unqualified)																					
0x1	Pilot Production (unqualified)																					
0x2	Fully Qualified																					

Register 3: Power-Temp Brown Out Control (PTBOCTL), offset 0x038

This register determines, based on an individual event level, the appropriate next level of action (for example, NONE, System Control Interrupt, NMI, or reset) when an event occurs.

Power-temperature event actions are directed to the core as a System Control Interrupt or NMI. When a reset occurs, its behavior is controlled by the **Reset Behavior Control (RESBEHAVCTL)** register. If one of the events configured in the **PTBOCTL** register causes a reset, it is registered as a BOR interrupt in the **Reset Cause (RESC)** register.

Note: V_{DDA} is the supply voltage to the analog components of the device and V_{DD} is the supply voltage to the digital components of the device.

Power-Temp Brown Out Control (PTBOCTL)

Base 0x400F.E000
Offset 0x038
Type RW, reset 0x0000.0003

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:8	VDDA_UBOR	RW	0	<p>V_{DDA} under BOR Event Action</p> <p>An event occurs when V_{DDA} trips under the V_{DDA_BOR0} threshold found in Table 32-13 on page 2105.</p> <p>This field determines the action to take on the event.</p>

Value	Description
0x0	No Action
0x1	System control interrupt
0x2	NMI
0x3	Reset

7:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
-----	----------	----	---	---

Bit/Field	Name	Type	Reset	Description										
1:0	VDD_UBOR	RW	0x3	<p>V_{DD} under BOR Event Action</p> <p>An event occurs when V_{DD} trips under the V_{DD_BOR} threshold found in Table 32-13 on page 2105.</p> <p>This field determines the action to take on the event.</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>No Action</td></tr><tr><td>0x1</td><td>System control interrupt</td></tr><tr><td>0x2</td><td>NMI</td></tr><tr><td>0x3</td><td>Reset</td></tr></tbody></table>	Value	Description	0x0	No Action	0x1	System control interrupt	0x2	NMI	0x3	Reset
Value	Description													
0x0	No Action													
0x1	System control interrupt													
0x2	NMI													
0x3	Reset													

Register 4: Raw Interrupt Status (RIS), offset 0x050

This register indicates the status for system control raw interrupts. An interrupt is sent to the interrupt controller if the corresponding bit in the **Interrupt Mask Control (IMC)** register is set. Writing a 1 to the corresponding bit in the **Masked Interrupt Status and Clear (MISC)** register clears an interrupt status bit.

Raw Interrupt Status (RIS)

Base 0x400F.E000
Offset 0x050
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPRIS	RO	0	MOSC Power Up Raw Interrupt Status
		Value	Description	
		0	Sufficient time has not passed for the MOSC to reach the expected frequency.	
		1	Sufficient time has passed for the MOSC to reach the expected frequency. The value for this power-up time is indicated by T_{MOSC_START} .	
				This bit is cleared by writing a 1 to the MOSCPUPMIS bit in the MISC register.
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PLLLRIS	RO	0	PLL Lock Raw Interrupt Status
		Value	Description	
		0	The PLL timer has not reached T_{READY} .	
		1	The PLL timer has reached T_{READY} indicating that sufficient time has passed for the PLL to lock.	
				This bit is cleared by writing a 1 to the PLLLMIS bit in the MISC register.
5:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
3	MOFRIS	RO	0	Main Oscillator Failure Raw Interrupt Status Value Description 0 The main oscillator has not failed. 1 The MOSCIM bit in the MOSCCTL register is set and the main oscillator has failed. This bit is cleared by writing a 1 to the MOFMIS bit in the MISC register.
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORRIS	RO	0	Brown-Out Reset Raw Interrupt Status Value Description 0 A brown-out condition is not currently active. 1 A brown-out condition is currently active. The appropriate BOR bit in the PTBOCTL register must be set to an interrupt (0x1) encoding in order to generate an interrupt. This bit is cleared by writing a 1 to the BORMIS bit in the MISC register.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 5: Interrupt Mask Control (IMC), offset 0x054

This register contains the mask bits for system control raw interrupts. A raw interrupt, indicated by a bit being set in the **Raw Interrupt Status (RIS)** register, is sent to the interrupt controller if the corresponding bit in this register is set.

Interrupt Mask Control (IMC)

Base 0x400F.E000
Offset 0x054
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPIM	RW	0	MOSC Power Up Interrupt Mask
	Value	Description		
	0	The MOSCPUPRIS interrupt is suppressed and not sent to the interrupt controller.		
	1	An interrupt is sent to the interrupt controller when the MOSCPUPRIS bit in the RIS register is set.		
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PLLIM	RW	0	PLL Lock Interrupt Mask
	Value	Description		
	0	The PLLLRIS interrupt is suppressed and not sent to the interrupt controller.		
	1	An interrupt is sent to the interrupt controller when the PLLLRIS bit in the RIS register is set.		
5:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
3	MOFIM	RW	0	Main Oscillator Failure Interrupt Mask Value Description 0 The MOFRIS interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the MOFRIS bit in the RIS register is set.
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORIM	RW	0	Brown-Out Reset Interrupt Mask Value Description 0 The BORRIS interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the BORRIS bit in the RIS register is set.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 6: Masked Interrupt Status and Clear (MISC), offset 0x058

On a read, this register gives the current masked status value of the corresponding interrupt in the **Raw Interrupt Status (RIS)** register. All of the bits are RW1C, thus writing a 1 to a bit clears the corresponding raw interrupt bit in the **RIS** register (see page 272).

Masked Interrupt Status and Clear (MISC)

Base 0x400F.E000
Offset 0x058
Type RW1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPMIS	RW1C	0	MOSC Power Up Masked Interrupt Status
	Value	Description		
	0	When read, a 0 indicates that sufficient time has not passed for the MOSC PLL to lock. A write of 0 has no effect on the state of this bit.		
	1	When read, a 1 indicates that an unmasked interrupt was signaled because sufficient time has passed for the MOSC PLL to lock. Writing a 1 to this bit clears it and also the MOSCPUPRIS bit in the RIS register.		
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PLLLMIS	RW1C	0	PLL Lock Masked Interrupt Status
	Value	Description		
	0	When read, a 0 indicates that sufficient time has not passed for the PLL to lock. A write of 0 has no effect on the state of this bit.		
	1	When read, a 1 indicates that an unmasked interrupt was signaled because sufficient time has passed for the PLL to lock. Writing a 1 to this bit clears it and also the PLLLRIS bit in the RIS register.		

Bit/Field	Name	Type	Reset	Description
5:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	MOFMIS	RW1C	0	Main Oscillator Failure Masked Interrupt Status Value Description 0 When read, a 0 indicates that the main oscillator has not failed. A write of 0 has no effect on the state of this bit. 1 When read, a 1 indicates that an unmasked interrupt was signaled because the main oscillator failed. Writing a 1 to this bit clears it and also the MOFRIS bit in the RIS register.
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORMIS	RW1C	0	BOR Masked Interrupt Status Value Description 0 When read, a 0 indicates that a brown-out condition has not occurred. A write of 0 has no effect on the state of this bit. 1 When read, a 1 indicates that an unmasked interrupt was signaled because of a brown-out condition. Writing a 1 to this bit clears it and also the BORRIS bit in the RIS register.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 7: Reset Cause (RESC), offset 0x05C

This register is set with the reset cause after reset. The bits in this register are sticky and maintain their state across multiple reset sequences. If a full POK-POR is initiated, the POR bit in the **RESC** register is set and all other bits are cleared. If the WDOGn, BOR or EXTRES configuration fields are set to 0x3 in the **RESBEHAVCTL** register and a simulated POR is initiated, the cause of the reset is reflected in the **RESC** register. A reset caused by a Hibernation wake event is also registered in **RESC** and the specific wake event can be found by reading the **Hibernation Raw Interrupt Status (HIBRIS)** register.

Note: The **Reset Cause (RESC)** register identifies if the Hibernation Module was a cause of a reset if the **HIB** bit is set. If the V_{DD} supply drops below the Power-On Reset threshold after being above the threshold for 1-2 hibernate clock cycles (typical 30 to 60 μ S), the **RESC** register does not show the Hibernation Module as a reset cause. Software may determine if the Hibernation module is configured and a wake-up source has triggered by reading the **Hibernation Control (HIBCTL)** register and the **Hibernation Raw Interrupt Status (HIBRIS)** register.

Reset Cause (RESC)

1	When read, this bit indicates that an external reset (\overline{RST} assertion) has caused a reset event.									

Register 8: Power-Temperature Cause (PWRTC), offset 0x060

This register provides detailed information on the power subsystem event that caused a reset or interrupt. The event sets the condition in this register without regard to whether it is used to generate a System control Interrupt, Reset, NMI, or no action. The **PTBOCTL** register contains the action to be taken on the specific events. The combination of the **PWRTC** register outputs and the **PTBOCTL** register causes the appropriate interrupt or reset condition to occur and the corresponding status bits to be set.

Power-Temperature Cause (PWRTC)

Base 0x400F.E000
Offset 0x060
Type RW1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	VDDA_UBOR	RW1C	0	V _{DDA} Under BOR Status
				Value Description
			0	V _{DDA} has not tripped under voltage BOR comparison.
			1	V _{DDA} has tripped under voltage BOR comparison.
3:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	VDD_UBOR	RW1C	0	V _{DD} Under BOR Status
				Value Description
			0	V _{DD} has not tripped under voltage BOR comparison.
			1	V _{DD} has tripped under voltage BOR comparison.

Register 9: NMI Cause Register (NMIC), offset 0x064

This register provides the detailed information on the cause of an NMI interrupt. These bits are set via hardware when the event occurs AND the higher level control indicates that it should be NMI event.

Note: The **NMIC** register has to be cleared by the following sequence:

1. Read the **NMIC** register to identify the source of the NMI.
2. Clear the source of the NMI.
3. Read the **NMIC** register again to check the status.
4. Write a 0 into the **NMIC** register bit that corresponds with the NMI source.
5. Read the **NMIC** to check whether it is cleared. If not, repeat 3 on page 282 and 4 on page 282 again.

Register 10: Main Oscillator Control (MOSCCTL), offset 0x07C

This register provides control over the features of the main oscillator, including the ability to enable the MOSC clock verification circuit, what action to take when the MOSC fails, and whether or not a crystal is connected. When enabled, this circuit monitors the frequency of the MOSC to verify that the oscillator is operating within specified limits. If the clock goes invalid after being enabled, the microcontroller issues a power-on reset and reboots to the NMI handler or generates an interrupt.

Note: If the MOSC is chosen as the clock to the Ethernet PHY then software has to enable the MOSC before enabling the Ethernet PHY by setting the P0 bit in the **PCEPHY**.

Bit/Field	Name	Type	Reset	Description
31	MEMTIMU	R0/W	0	Memory Timing Register Update Setting this bit causes the MEMTIM0 register value to be applied, and the memory timing to be updated. Execution and access is suspended during the change. This bit is automatically cleared by hardware.
30	NEWFREQ	R0/W	0	New PLLFREQ Accept This bit controls the activation of the values in the PLLREQ0 and PLLREQ1 registers as applied to the PLL. Until NEWFREQ is written to a 1, writes to the PLLREQ0 and PLLREQ1 are deferred. When written with a 1, the values stored in PLLREQ0 and PLLREQ1 are applied to the PLL. This bit is automatically cleared by hardware. Software will not check the value after being set.
29	ACG	RW	0x0	Auto Clock Gating This bit specifies whether the system uses the Sleep-Mode Clock Gating Control (SCGCn) registers and Deep-Sleep-Mode Clock Gating Control (DCGCn) registers if the microcontroller enters a Sleep or Deep-Sleep mode (respectively).

Value	Description
0	The Run-Mode Clock Gating Control (RCGCn) registers are used when the microcontroller enters a sleep mode.
1	If the microcontroller is in sleep mode, the SCGCn registers are used to control the clocks distributed to the peripherals. If the microcontroller is in deep-sleep mode, the DCGCn registers are used to control the clocks distributed to the peripherals. The SCGCn and DCGCn registers allow unused peripherals to consume less power when the microcontroller is in a sleep mode.

The **RCGCn** registers are always used to control the clocks in Run mode.

Register 12: Memory Timing Parameter Register 0 for Main Flash and EEPROM (MEMTIM0), offset 0x0C0

The **MEMTIM0** register provides timing parameters for the main Flash and EEPROM memories. The timing parameters apply to the memory while the system is in run or sleep mode; the clocking for these modes is consistent and unchanged since the system clock frequency and source remains unchanged during transitions between run-to-sleep and sleep-back-to-run. Writes to **MEMTIM0** do not have any effect on system state; the register contents are applied only when the **MEMTIMU** bit in the **RSCLKCFG** register is set. Doing so allows the software to execute out of the same memory system for which the timing parameters are being modified.

Depending on the CPU frequency, the application must program specific values into the fields of the **Memory Timing Parameter Register 0 for Main Flash and EEPROM (MEMTIM0)**. The following table details the bit field values that are required for the given CPU frequency ranges.

Table 5-12. MEMTIM0 Register Configuration versus Frequency

CPU Frequency range (f) in MHz	Time Period Range (t) in ns	FBCHT/EBCHT	FBCE/EBCE	FWS/EWS
16	62.5	0x0	1	0x0
16 < f ≤ 40	62.5 > t ≥ 25	0x2	0	0x1
40 < f ≤ 60	25 > t ≥ 16.67	0x3	0	0x2
60 < f ≤ 80	16.67 > t ≥ 12.5	0x4	0	0x3
80 < f ≤ 100	12.5 > t ≥ 10	0x5	0	0x4
100 < f ≤ 120	10 > t ≥ 8.33	0x6	0	0x5

Note: The associated Flash and EEPROM fields in the **MEMTIM0** register must be programmed to the same values. For example, the **FWS** field must be programmed to the same value as the **EWS** field.

Refer to “Flash Memory” on page 634 and “EEPROM” on page 645 for more information about Flash and EEPROM programming.

Register 13: Alternate Clock Configuration (ALTCLKCFG), offset 0x138

The **ALTCLKCFG** register specifies the alternate clock source used by many of the peripherals.

Alternate Clock Configuration (ALTCLKCFG)

Base 0x400F.E000
Offset 0x138
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	ALTCLK	RW	0x0	Alternate Clock Source This provides a clock source of numerous frequencies to the general-purpose timer, SSI, and UART modules. Note that if the Hibernation Real-time Clock Output is selected, the clock source must also be enabled in the Hibernation module.

Value	Description
0x0	PIOSC
0x1-0x2	reserved
0x3	Hibernation Module Real-time clock output (RTCOSC)
0x4	Low-frequency internal oscillator (LFIOSC)
0x5-0x15	reserved

Register 14: Deep Sleep Clock Configuration Register (DSCLKCFG), offset 0x144

The **DSCLKCFG** register specifies the behavior of the clock system while in deep sleep.

Note that the MOSCDPD bit not only affects deep-sleep mode, but all other modes as well depending on the value of the bit. Please refer to the following table when programming this bit:

Table 5-13. MOSC Configurations

PWRDN bit	MOSCDPD field	Result
0	0	MOSC is powered ON in run and sleep modes, but is disabled in accidental power down, when the PWRDN bit is set in the MOSCCTL register, or in deep-sleep mode only if it is not the deep-sleep clock source (DSOSCSRC != 0x3).
0	1	MOSC is powered and running in run, sleep and deep-sleep modes.
1	0	MOSC is powered off, and does not run in any mode. Please note, that in this configuration, when the MOSC is disabled, the MOSC must not be chosen as a clock source or indeterminate results occur.
1	1	MOSC runs and does not disable itself in run, sleep, and deep-sleep modes regardless of the fact that the PWRDN bit is set.

Note: The MOSCDPD bit has an effect in all modes of operation

Note: If the MOSC is chosen as the Deep-Sleep clock source in the **DSCLKCFG** register, the MOSC must also be configured as the Run and Sleep clock source in the **RSCLKCFG** register prior to entering Deep Sleep. If the PIOSC, LFIOSC, or Hibernation RTC Module Oscillator (HIBLFIOSC or 32-kHz crystal) is configured as the Run and Sleep clock source in the **RSCLKFCFG** register, and the MOSC is configured as the Deep-Sleep clock source in the **DSCLKCFG** register, then two outcomes are possible:

- If the PIOSC is still powered in Deep Sleep (using the PIOSCPD bit in the **DSCLKCFG** register) then the PIOSC is utilized as the clock source when entering Deep Sleep and the device enters and exits the Deep-Sleep state normally. The MOSC is not used as the clock source in Deep Sleep.
- If the PIOSC has been configured to be powered down in Deep Sleep, then the device can enter the Deep-Sleep state, but cannot exit properly. This situation can be avoided by programming the MOSC as the Run and Sleep clock source in the **RSCLKCFG** register prior to entering Deep Sleep.

Register 19: PLL Frequency 0 (PLLFREQ0), offset 0x160

This register always contains the variables used to configure the PLL. If the PLL is reprogrammed, it must go through a relock sequence which is defined by the parameter T_{READY} in Table 32-16 on page 2113. When controlling this register directly, software must change this value while the PLL is powered down. Writes to **PLLFREQ0** are delayed from affecting the PLL until the **RSCLKCFG** register NEWFREQ bit is written with a 1.

The PLL frequency can be calculated using the following equation:

$$f_{VCO} = (f_{IN} * MDIV)$$

where

$$f_{IN} = f_{XTAL}/(Q+1)(N+1) \text{ or } f_{PIOOSC}/(Q+1)(N+1)$$

$$MDIV = MINT + (MFRAC / 1024)$$

The Q and N values are programmed in the **PLLFREQ1** register. Note that to reduce jitter, MFRAC should be programmed to 0x0.

PLL Frequency 0 (PLLFREQ0)

Base 0x400F.E000
Offset 0x160
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description

23	PLLPWR	RW	0	PLL Power This bit controls power to the PLL. If set, the PLL power is applied and the PLL will oscillate based on the values in the PLLFREQ0 and PLLFREQ1 registers.
22:20	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19:10	MFRAC	RW	0	PLL M Fractional Value
9:0	MINT	RW	0x00	PLL M Integer Value This field contains the integer value of the PLL M value.

Register 20: PLL Frequency 1 (PLLFREQ1), offset 0x164

This register always contains the current Q and N values presented to the system PLL. If the PLL is reconfigured, it must go through a relock sequence which takes about 128 PIOSC clocks. When controlling this register directly, software must change this value while the PLL is powered down. Writes to **PLLFREQ0** are delayed from affecting the PLL until the **RSCLKCFG** register NEWFREQ bit is written with a 1.

The MINT and MFRAC fields are present in the **PLLFREQ0** register.

7:0	30KHZ	RO	0x12	Deep-Sleep with IOSC The value in this field is the suggested value for the VLDO field in the LDODPCTL register when not using the PLL. This value provides the lowest recommended LDO output voltage for use with the low-frequency internal oscillator.

Register 29: Sleep / Deep-Sleep Power Mode Status (SDPMST), offset 0x1CC

This register provides status information on the Sleep and Deep-Sleep power modes as well as some real time status that can be viewed by a debugger or the core if it is running. These events do not trigger an interrupt and are meant to provide information that can help tune software for power management. The status register gets written at the beginning of every Dynamic Power Management event request with the results of any error checking. There is no mechanism to clear the bits; they are overwritten on the next event. The LDOUA, FLASHLP, LOWPWR, PRACT bits provide real time data and there are no events to register that information.

1	An error has occurred because software has requested an SRAM power down mode that is not available using the SRAMPM field in the SLPPWRCFG or the DSLPPWRCFG register.									

Register 30: Reset Behavior Control Register (RESBEHAVCTL), offset 0x1D8

The Reset Behavior Control Register contains system management controls.

The **RESBEHAVCTL** register effect occurs immediately when the register is changed. The next power-on reset sequence returns the reset value.

If any bit field below is set to 0x3 when a reset occurs, a simulated POR will be generated and the appropriate reset cause will be set in the **Reset Cause (RESC)** register. During a simulated POR, registers are reloaded and the bootloader is executed. If a full POR is initiated the POR bit in the **RESC** register will be set and all other bits will be cleared.

Reset Behavior Control Register (RESBEHAVCTL)

Base 0x400F.E000
Offset 0x1D8
Type RW, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0xFFFF.FF	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

0x2	External $\overline{\text{RST}}$ assertion issues a system reset.											
0x3	External $\overline{\text{RST}}$ assertion issues a simulated POR sequence (default).											

Register 31: Hardware System Service Request (HSSR), offset 0x1F4

The **HSSR** register is used to control system configuration functions, such as Return-to-Factory settings. A write to the **HSSR** register stores a command descriptor pointer (**CDOFF**) value if the **KEY** field is correct (0xCA). A successful write to this register also initiates a system reset. The initialization process executes before examining the **HSSR** register and processing the command. This register can only be accessed in privilege mode. Refer to “Hardware System Service Request” on page 255 for more information on how to use the **HSSR** register.

Hardware System Service Request (HSSR)

Base 0x400F.E000

31:24	KEY	R0/W	0	<p>Write Key</p> <p>When read, this field returns zero.</p> <p>When written, this field must contain the value of 0xCA in order to register the CDOFF field and initiate a HSSR request. Writes with KEY values other than 0xCA are ignored.</p>
23:0	CDOFF	RW	0	<p>Command Descriptor Pointer</p> <p>This field contains either the status result from the previous HSSR request, or it contains a (word-aligned) memory address where the command descriptor is located.</p> <p>If CDOFF = 0x00.0000, it indicates there is no request and no processing is performed.</p> <p>If CDOFF = 0xFF.FFFF, it indicates that the previous request through HSSR did not complete due to an error.</p> <p>Otherwise, CDOFF contains the offset for a data structure in SRAM.</p>

Register 32: USB Power Domain Status (USBPDS), offset 0x280

This register provides the status of power to the USB SRAM memory array.

Note: If the **USBMPC** register's PWRCTL field is set to 0x3 and the power domain to the USB is turned off by writing a 0 to the P0 bit of the **PCUSB** register, then the SRAM memory goes into retention and the MEMSTAT field of the **USBPDS** register reads as 0x1 (retention).

USB Power Domain Status (USBPDS)

Base 0x400F.E000
Offset 0x280
Type RO, reset 0x0000.003F

Bit/Field	Name	Type	Reset	Description

31:18	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
17	P17	RO	0x1	GPIO Port T Present
		Value	Description	
		0	GPIO Port T is not present.	
		1	GPIO Port T is present.	
16	P16	RO	0x1	GPIO Port S Present
		Value	Description	
		0	GPIO Port S is not present.	
		1	GPIO Port S is present.	
15	P15	RO	0x1	GPIO Port R Present
		Value	Description	
		0	GPIO Port R is not present.	
		1	GPIO Port R is present.	
14	P14	RO	0x1	GPIO Port Q Present
		Value	Description	
		0	GPIO Port Q is not present.	
		1	GPIO Port Q is present.	

Bit/Field	Name	Type	Reset	Description
13	P13	RO	0x1	GPIO Port P Present Value Description 0 GPIO Port P is not present. 1 GPIO Port P is present.
12	P12	RO	0x1	GPIO Port N Present Value Description 0 GPIO Port N is not present. 1 GPIO Port N is present.
11	P11	RO	0x1	GPIO Port M Present Value Description 0 GPIO Port M is not present. 1 GPIO Port M is present.
10	P10	RO	0x1	GPIO Port L Present Value Description 0 GPIO Port L is not present. 1 GPIO Port L is present.
9	P9	RO	0x1	GPIO Port K Present Value Description 0 GPIO Port K is not present. 1 GPIO Port K is present.
8	P8	RO	0x1	GPIO Port J Present Value Description 0 GPIO Port J is not present. 1 GPIO Port J is present.
7	P7	RO	0x1	GPIO Port H Present Value Description 0 GPIO Port H is not present. 1 GPIO Port H is present.

Bit/Field	Name	Type	Reset	Description
6	P6	RO	0x1	GPIO Port G Present Value Description 0 GPIO Port G is not present. 1 GPIO Port G is present.
5	P5	RO	0x1	GPIO Port F Present Value Description 0 GPIO Port F is not present. 1 GPIO Port F is present.
4	P4	RO	0x1	GPIO Port E Present Value Description 0 GPIO Port E is not present. 1 GPIO Port E is present.
3	P3	RO	0x1	GPIO Port D Present Value Description 0 GPIO Port D is not present. 1 GPIO Port D is present.
2	P2	RO	0x1	GPIO Port C Present Value Description 0 GPIO Port C is not present. 1 GPIO Port C is present.
1	P1	RO	0x1	GPIO Port B Present Value Description 0 GPIO Port B is not present. 1 GPIO Port B is present.
0	P0	RO	0x1	GPIO Port A Present Value Description 0 GPIO Port A is not present. 1 GPIO Port A is present.

Register 45: Micro Direct Memory Access Peripheral Present (PPDMA), offset 0x30C

The PPDMA register provides software information regarding the µDMA module.

Important: This register should be used to determine if the µDMA module is implemented on this microcontroller.

Micro Direct Memory Access Peripheral Present (PPDMA)

Base 0x400F.E000

Offset 0x30C

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	µDMA Module Present
		Value	Description	
		0	µDMA module is not present.	
		1	µDMA module is present.	

Register 46: EPI Peripheral Present (PPEPI), offset 0x310

The **PPEPI** register provides software information regarding the EPI module.

Important: This register should be used to determine if the EPI module is implemented on this microcontroller.

EPI Peripheral Present (PPEPI)

Base 0x400F.E000

Offset 0x310

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	EPI Module Present
		Value		Description
		0		EPI module is not present.
		1		EPI module is present.

Register 47: Hibernation Peripheral Present (PPHIB), offset 0x314

The **PPHIB** register provides software information regarding the Hibernation module.

Important: This register should be used to determine if the Hibernation module is implemented on this microcontroller.

Hibernation Peripheral Present (PPHIB)

Base 0x400FE000

Offset 0x314

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	Hibernation Module Present
	Value	Description		
	0	Hibernation module is not present.		
	1	Hibernation module is present.		

Register 48: Universal Asynchronous Receiver/Transmitter Peripheral Present (PPUART), offset 0x318

The PPUART register provides software information regarding the UART modules.

Important: This register should be used to determine which UART modules are implemented on this microcontroller.

Universal Asynchronous Receiver/Transmitter Peripheral Present (PPUART)

Base 0x400F.E000

Offset 0x318

Type RO, reset 0x0000.00FF

		Value	Description	
		0	UART module 4 is not present.	
		1	UART module 4 is present.	

Bit/Field	Name	Type	Reset	Description
3	P3	RO	0x1	UART Module 3 Present Value Description 0 UART module 3 is not present. 1 UART module 3 is present.
2	P2	RO	0x1	UART Module 2 Present Value Description 0 UART module 2 is not present. 1 UART module 2 is present.
1	P1	RO	0x1	UART Module 1 Present Value Description 0 UART module 1 is not present. 1 UART module 1 is present.
0	P0	RO	0x1	UART Module 0 Present Value Description 0 UART module 0 is not present. 1 UART module 0 is present.

Register 49: Synchronous Serial Interface Peripheral Present (PPSSI), offset 0x31C

The PPSSI register provides software information regarding the SSI modules.

Important: This register should be used to determine which SSI modules are implemented on this microcontroller. However, to support legacy software, the DC2 register is available. A read of the DC2 register correctly identifies if a legacy SSI module is present. Software must use this register to determine if a module that is not supported by the DC2 register is present.

Synchronous Serial Interface Peripheral Present (PPSSI)

Base 0x400F.E000
Offset 0x31C
Type RO, reset 0x0000.000F

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	P3	RO	0x1	SSI Module 3 Present
		Value	Description	
		0	SSI module 3 is not present.	
		1	SSI module 3 is present.	
2	P2	RO	0x1	SSI Module 2 Present
		Value	Description	
		0	SSI module 2 is not present.	
		1	SSI module 2 is present.	
1	P1	RO	0x1	SSI Module 1 Present
		Value	Description	
		0	SSI module 1 is not present.	
		1	SSI module 1 is present.	

Bit/Field	Name	Type	Reset	Description
0	P0	RO	0x1	SSI Module 0 Present
				Value Description
			0	SSI module 0 is not present.
			1	SSI module 0 is present.

Register 50: Inter-Integrated Circuit Peripheral Present (PPI2C), offset 0x320

The PPI2C register provides software information regarding the I²C modules.

Important: This register should be used to determine which I²C modules are implemented on this microcontroller.

Inter-Integrated Circuit Peripheral Present (PPI2C)

Base 0x400F.E000

Offset 0x320

Type RO, reset 0x0000.03FF

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	P9	RO	0x1	I ² C Module 9 Present
		Value	Description	
		0	I ² C module 9 is not present.	
		1	I ² C module 9 is present.	
8	P8	RO	0x1	I ² C Module 8 Present
		Value	Description	
		0	I ² C module 8 is not present.	
		1	I ² C module 8 is present.	
7	P7	RO	0x1	I ² C Module 7 Present
		Value	Description	
		0	I ² C module 7 is not present.	
		1	I ² C module 7 is present.	
6	P6	RO	0x1	I ² C Module 6 Present
		Value	Description	
		0	I ² C module 6 is not present.	
		1	I ² C module 6 is present.	

Bit/Field	Name	Type	Reset	Description
5	P5	RO	0x1	I ² C Module 5 Present Value Description 0 I ² C module 5 is not present. 1 I ² C module 5 is present.
4	P4	RO	0x1	I ² C Module 4 Present Value Description 0 I ² C module 4 is not present. 1 I ² C module 4 is present.
3	P3	RO	0x1	I ² C Module 3 Present Value Description 0 I ² C module 3 is not present. 1 I ² C module 3 is present.
2	P2	RO	0x1	I ² C Module 2 Present Value Description 0 I ² C module 2 is not present. 1 I ² C module 2 is present.
1	P1	RO	0x1	I ² C Module 1 Present Value Description 0 I ² C module 1 is not present. 1 I ² C module 1 is present.
0	P0	RO	0x1	I ² C Module 0 Present Value Description 0 I ² C module 0 is not present. 1 I ² C module 0 is present.

Register 51: Universal Serial Bus Peripheral Present (PPUSB), offset 0x328

The **PPUSB** register provides software information regarding the USB module.

Important: This register should be used to determine if the USB module is implemented on this microcontroller.

Universal Serial Bus Peripheral Present (PPUSB)

Base 0x400F.E000

Offset 0x328

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	USB Module Present
	Value	Description		
	0	USB module is not present.		
	1	USB module is present.		

Register 52: Ethernet PHY Peripheral Present (PPEPHY), offset 0x330

The **PPEPHY** register provides software information regarding the Ethernet PHY module.

Important: This register should be used to determine if the Ethernet PHY module is implemented on this microcontroller.

Ethernet PHY Peripheral Present (PPEPHY)

Base 0x400F.E000

Offset 0x330

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	Ethernet PHY Module Present
		Value	Description	
		0	Ethernet PHY module is not present.	
		1	Ethernet PHY module is present.	

Register 53: Controller Area Network Peripheral Present (PPCAN), offset 0x334

The PPCAN register provides software information regarding the CAN modules.

Important: This register should be used to determine which CAN modules are implemented on this microcontroller.

Controller Area Network Peripheral Present (PPCAN)

Base 0x400FE000

Offset 0x334

Type RO, reset 0x0000.0003

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	P1	RO	0x1	CAN Module 1 Present
		Value	Description	
		0	CAN module 1 is not present.	
		1	CAN module 1 is present.	
0	P0	RO	0x1	CAN Module 0 Present
		Value	Description	
		0	CAN module 0 is not present.	
		1	CAN module 0 is present.	

Register 54: Analog-to-Digital Converter Peripheral Present (PPADC), offset 0x338

The PPADC register provides software information regarding the ADC modules.

Important: This register should be used to determine which ADC modules are implemented on this microcontroller.

Analog-to-Digital Converter Peripheral Present (PPADC)

Base 0x400F.E000

Offset 0x338

Type RO, reset 0x0000.0003

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	P1	RO	0x1	ADC Module 1 Present
		Value	Description	
		0	ADC module 1 is not present.	
		1	ADC module 1 is present.	
0	P0	RO	0x1	ADC Module 0 Present
		Value	Description	
		0	ADC module 0 is not present.	
		1	ADC module 0 is present.	

Register 55: Analog Comparator Peripheral Present (PPACMP), offset 0x33C

The **PPACMP** register provides software information regarding the analog comparator module.

Important: This register should be used to determine if the analog comparator module is implemented on this microcontroller.

Note that the **Analog Comparator Peripheral Properties (ACMPPP)** register indicates how many analog comparator blocks are included in the module.

Analog Comparator Peripheral Present (PPACMP)

Base 0x400F.E000

Offset 0x33C

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	Analog Comparator Module Present
		Value	Description	
		0	Analog comparator module is not present.	
		1	Analog comparator module is present.	

Register 56: Pulse Width Modulator Peripheral Present (PPPWM), offset 0x340

The **PPPWM** register provides software information regarding the PWM modules.

Important: This register should be used to determine which PWM modules are implemented on this microcontroller.

Pulse Width Modulator Peripheral Present (PPPWM)

Base 0x400F.E000

Offset 0x340

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	PWM Module 0 Present
		Value	Description	
		0	PWM module 0 is not present.	
		1	PWM module 0 is present.	

Register 57: Quadrature Encoder Interface Peripheral Present (PPQEI), offset 0x344

The PPQEI register provides software information regarding the QEI modules.

Important: This register should be used to determine which QEI modules are implemented on this microcontroller.

Quadrature Encoder Interface Peripheral Present (PPQEI)

Base 0x400F.E000

Offset 0x344

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	QEI Module 0 Present
		Value	Description	
		0	QEI module 0 is not present.	
		1	QEI module 0 is present.	

Register 58: Low Pin Count Interface Peripheral Present (PPLPC), offset 0x348

The PPLPC register provides software information regarding the LPC module.

Low Pin Count Interface Peripheral Present (PPLPC)

Base 0x400F.E000
Offset 0x348
Type RO, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:1 reserved RO 0 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

0 P0 RO 0x0 LPC Module Present

Value	Description
0	LPC module is not present.
1	LPC module is present.

Register 59: Platform Environment Control Interface Peripheral Present (PPPECI), offset 0x350

The **PPPECI** register provides software information regarding the PECL module.

Platform Environment Control Interface Peripheral Present (PPPECI)

Base 0x400F.E000
Offset 0x350
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x0	PECL Module Present
		Value	Description	
		0	PECL module is not present.	
		1	PECL module is present.	

Register 60: Fan Control Peripheral Present (PPFAN), offset 0x354

The PPFAN register provides software information regarding the FAN module.

Fan Control Peripheral Present (PPFAN)

Base 0x400F.E000
Offset 0x354
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:1 reserved RO 0 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

0 P0 RO 0x0 FAN Module 0 Present

Value	Description
0	FAN module is not present.
1	FAN module is present.

Register 61: EEPROM Peripheral Present (PPEEPROM), offset 0x358

The **PPEEPROM** register provides software information regarding the EEPROM module.

EEPROM Peripheral Present (PPEEPROM)

Base 0x400F.E000
Offset 0x358
Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	EEPROM 0 Module Present
		Value	Description	
		0	EEPROM module is not present.	
		1	EEPROM module is present.	

Register 62: 32/64-Bit Wide General-Purpose Timer Peripheral Present (PPWTIMER), offset 0x35C

The **PPWTIMER** register provides software information regarding the 32/64-bit wide general-purpose timer modules.

32/64-Bit Wide General-Purpose Timer Peripheral Present (PPWTIMER)

Base 0x400F.E000

Offset 0x35C

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x0	32/64-Bit Wide General-Purpose Timer 0 Present
		Value	Description	
	0	32/64-bit wide general-purpose timer module 0 is not present.		
	1	32/64-bit wide general-purpose timer module 0 is present.		

Register 63: Remote Temperature Sensor Peripheral Present (PPRTS), offset 0x370

The **PPRTS** register provides software information regarding the Remote Temperature Sensor (RTS) module.

Important: This register should be used to determine which RTS modules are implemented on this microcontroller.

Remote Temperature Sensor Peripheral Present (PPRTS)

Base 0x400F.E000
Offset 0x370
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x0	RTS Module Present
		Value	Description	
		0		RTS module is not present.
		1		RTS module is present.

Register 64: CRC and Cryptographic Modules Peripheral Present (PPCCM), offset 0x374

The **PPCCM** register provides software information regarding the CRC and Cryptographic Modules (AES, DES, and SHA).

Important: This register should be used to determine if the CRC and Cryptographic Modules (AES, DES, SHA/MD5) are implemented on this microcontroller.

CRC and Cryptographic Modules Peripheral Present (PPCCM)

Base 0x400F.E000

Offset 0x374

Type RO, reset 0x0000.0001

0	P0	RO	0x1	CRC and Cryptographic Modules Present
		Value	Description	
		0	The CRC, AES, DES, and SHA/MD modules are not present.	
		1	The CRC, AES, DES, and SHA/MD modules are present.	

Register 65: LCD Peripheral Present (PPLCD), offset 0x390

The PPLCD register provides software information regarding the LCD module.

Important: This register should be used to determine if an LCD controller is implemented on this microcontroller.

LCD Peripheral Present (PPLCD)

Base 0x400F.E000

Offset 0x390

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	LCD Module Present
		Value	Description	
		0	LCD module is not present.	
		1	LCD module is present.	

Register 66: 1-Wire Peripheral Present (PPOWIRE), offset 0x398

The **PPOWIRE** register provides software information regarding the 1-Wire module.

Important: This register should be used to determine which 1-Wire modules are implemented on this microcontroller.

1-Wire Peripheral Present (PPOWIRE)

Base 0x400F.E000

Offset 0x398

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	1-Wire Module Present
		Value	Description	
		0	1	1-Wire module is not present.
		1	1	1-Wire module is present.

Register 67: Ethernet MAC Peripheral Present (PPEMAC), offset 0x39C

The **PPEMAC** register provides software information regarding the Ethernet controller module.

Important: This register should be used to determine which Ethernet controller modules are implemented on this microcontroller.

Ethernet MAC Peripheral Present (PPEMAC)

Base 0x400F.E000

Offset 0x39C

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x1	Ethernet Controller Module Present
		Value	Description	
		0	Ethernet Controller MAC module is not present.	
		1	Ethernet Controller MAC module is present.	

Register 68: Power Regulator Bus Peripheral Present (PPPRB), offset 0x3A0

The **PPPRB** register provides software information regarding the Power Regulator Bus module.

Important: This register should be used to determine which Power Regulator Bus modules are implemented on this microcontroller.

Power Regulator Bus Peripheral Present (PPPRB)

Base 0x400F.E000

Offset 0x3A0

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x0	PRB Module Present
		Value	Description	
		0	PRB module is not present.	
		1	PRB module is present.	

Register 69: Human Interface Master Peripheral Present (PPHIM), offset 0x3A4

The **PPHIM** register provides software information regarding the Human Interface Master (HIM) module.

Important: This register should be used to determine which HIM modules are implemented on this microcontroller.

Human Interface Master Peripheral Present (PPHIM)

Base 0x400F.E000
Offset 0x3A4
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RO	0x0	HIM Module Present
		Value	Description	
		0	HIM module is not present.	
		1	HIM module is present.	

Register 70: Watchdog Timer Software Reset (SRWD), offset 0x500

The **SRWD** register provides software the capability to reset the available watchdog modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRWD** register. While the **SRWD** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRWD** bit.

There may be latency from the clearing of the **SRWD** bit to when the peripheral is ready for use. Software should check the corresponding **PRWD** bit to verify that the Watchdog Timer Module registers are ready to be accessed.

Important: This register should be used to reset the watchdog modules.

Register 71: 16/32-Bit General-Purpose Timer Software Reset (SRTIMER), offset 0x504

The **SRTIMER** register provides software the capability to reset the available 16/32-bit timer modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRTIMER** register. While the **SRTIMER** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRTIMER** bit.

There may be latency from the clearing of the **SRTIMER** bit to when the peripheral is ready for use. Software should check the corresponding **PRTIMER** bit to verify that the Timer Module registers are ready to be accessed.

Important: This register should be used to reset the timer modules.

31:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	R1	RW	0	CAN Module 1 Software Reset Value Description 0 CAN module 1 is not reset. 1 CAN module 1 is reset.
0	R0	RW	0	CAN Module 0 Software Reset Value Description 0 CAN module 0 is not reset. 1 CAN module 0 is reset.

Register 82: Analog-to-Digital Converter Software Reset (SRADC), offset 0x538

The **SRADC** register provides software the capability to reset the available ADC modules.

A peripheral is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRADC** register. While the **SRADC** bit is 1, the peripheral is held in reset.
2. Software completes the reset process by clearing the **SRADC** bit.

There may be latency from the clearing of the **SRADC** bit to when the peripheral is ready for use. Software should check the corresponding **PRADC** bit to verify that the ADC Module registers are ready to be accessed.

Important: This register should be used to reset the ADC modules.

Register 83: Analog Comparator Software Reset (SRACMP), offset 0x53C

The **SRACMP** register provides software the capability to reset the available analog comparator module.

A block is reset by software using a simple two-step process:

1. Software sets a bit (or bits) in the **SRACMP** register. While the **SRACMP** bit is 1, the module is held in reset.
2. Software completes the reset process by clearing the **SRACMP** bit.

There may be latency from the clearing of the **SRACMP** bit to when the module is ready for use. Software should check the corresponding **PRACMP** bit to verify that the Analog Comparator Module registers are ready to be accessed.

Important: This register should be used to reset the analog comparator module.

		Value	Description	
		0	EPI module is disabled.	
		1	Enable and provide a clock to the EPI module in Run mode.	

Register 96: Hibernation Run Mode Clock Gating Control (RCGCHIB), offset 0x614

The **RCGCHIB** register provides software the capability to enable and disable the Hibernation module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the Hibernation module.

Hibernation Run Mode Clock Gating Control (RCGCHIB)

Base 0x400F.E000

Offset 0x614

Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RW	1	Hibernation Module Run Mode Clock Gating Control
		Value	Description	
		0	Hibernation module is disabled.	
		1	Enable and provide a clock to the Hibernation module in Run mode.	

Register 97: Universal Asynchronous Receiver/Transmitter Run Mode Clock Gating Control (RCGCUART), offset 0x618

The **RCGCUART** register provides software the capability to enable and disable the UART modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the UART modules.

Universal Asynchronous Receiver/Transmitter Run Mode Clock Gating Control (RCGCUART)

Base 0x400F.E000
Offset 0x618
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	R7	RW	0	UART Module 7 Run Mode Clock Gating Control
		Value	Description	
		0	UART module 7 is disabled.	
		1	Enable and provide a clock to UART module 7 in Run mode.	
6	R6	RW	0	UART Module 6 Run Mode Clock Gating Control
		Value	Description	
		0	UART module 6 is disabled.	
		1	Enable and provide a clock to UART module 6 in Run mode.	
5	R5	RW	0	UART Module 5 Run Mode Clock Gating Control
		Value	Description	
		0	UART module 5 is disabled.	
		1	Enable and provide a clock to UART module 5 in Run mode.	
4	R4	RW	0	UART Module 4 Run Mode Clock Gating Control
		Value	Description	
		0	UART module 4 is disabled.	
		1	Enable and provide a clock to UART module 4 in Run mode.	

Bit/Field	Name	Type	Reset	Description
3	R3	RW	0	UART Module 3 Run Mode Clock Gating Control Value Description 0 UART module 3 is disabled. 1 Enable and provide a clock to UART module 3 in Run mode.
2	R2	RW	0	UART Module 2 Run Mode Clock Gating Control Value Description 0 UART module 2 is disabled. 1 Enable and provide a clock to UART module 2 in Run mode.
1	R1	RW	0	UART Module 1 Run Mode Clock Gating Control Value Description 0 UART module 1 is disabled. 1 Enable and provide a clock to UART module 1 in Run mode.
0	R0	RW	0	UART Module 0 Run Mode Clock Gating Control Value Description 0 UART module 0 is disabled. 1 Enable and provide a clock to UART module 0 in Run mode.

Register 98: Synchronous Serial Interface Run Mode Clock Gating Control (RCGCSSI), offset 0x61C

The **RCGCSSI** register provides software the capability to enable and disable the SSI modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the SSI modules.

Synchronous Serial Interface Run Mode Clock Gating Control (RCGCSSI)

Base 0x400F.E000
Offset 0x61C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	R3	RW	0	SSI Module 3 Run Mode Clock Gating Control
		Value	Description	
		0	SSI module 3 is disabled.	
		1	Enable and provide a clock to SSI module 3 in Run mode.	
2	R2	RW	0	SSI Module 2 Run Mode Clock Gating Control
		Value	Description	
		0	SSI module 2 is disabled.	
		1	Enable and provide a clock to SSI module 2 in Run mode.	
1	R1	RW	0	SSI Module 1 Run Mode Clock Gating Control
		Value	Description	
		0	SSI module 1 is disabled.	
		1	Enable and provide a clock to SSI module 1 in Run mode.	
0	R0	RW	0	SSI Module 0 Run Mode Clock Gating Control
		Value	Description	
		0	SSI module 0 is disabled.	
		1	Enable and provide a clock to SSI module 0 in Run mode.	

Register 99: Inter-Integrated Circuit Run Mode Clock Gating Control (RCGCI2C), offset 0x620

The **RCGCI2C** register provides software the capability to enable and disable the I²C modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the I²C modules.

Inter-Integrated Circuit Run Mode Clock Gating Control (RCGCI2C)

Base 0x400F.E000
Offset 0x620
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	R9	RW	0	I ² C Module 9 Run Mode Clock Gating Control
		Value	Description	
		0	I ² C module 9 is disabled.	
		1	Enable and provide a clock to I ² C module 9 in Run mode.	
8	R8	RW	0	I ² C Module 8 Run Mode Clock Gating Control
		Value	Description	
		0	I ² C module 8 is disabled.	
		1	Enable and provide a clock to I ² C module 8 in Run mode.	
7	R7	RW	0	I ² C Module 7 Run Mode Clock Gating Control
		Value	Description	
		0	I ² C module 7 is disabled.	
		1	Enable and provide a clock to I ² C module 7 in Run mode.	

Bit/Field	Name	Type	Reset	Description
6	R6	RW	0	I ² C Module 6 Run Mode Clock Gating Control Value Description 0 I ² C module 6 is disabled. 1 Enable and provide a clock to I ² C module 6 in Run mode.
5	R5	RW	0	I ² C Module 5 Run Mode Clock Gating Control Value Description 0 I ² C module 5 is disabled. 1 Enable and provide a clock to I ² C module 5 in Run mode.
4	R4	RW	0	I ² C Module 4 Run Mode Clock Gating Control Value Description 0 I ² C module 4 is disabled. 1 Enable and provide a clock to I ² C module 4 in Run mode.
3	R3	RW	0	I ² C Module 3 Run Mode Clock Gating Control Value Description 0 I ² C module 3 is disabled. 1 Enable and provide a clock to I ² C module 3 in Run mode.
2	R2	RW	0	I ² C Module 2 Run Mode Clock Gating Control Value Description 0 I ² C module 2 is disabled. 1 Enable and provide a clock to I ² C module 2 in Run mode.
1	R1	RW	0	I ² C Module 1 Run Mode Clock Gating Control Value Description 0 I ² C module 1 is disabled. 1 Enable and provide a clock to I ² C module 1 in Run mode.
0	R0	RW	0	I ² C Module 0 Run Mode Clock Gating Control Value Description 0 I ² C module 0 is disabled. 1 Enable and provide a clock to I ² C module 0 in Run mode.

Register 100: Universal Serial Bus Run Mode Clock Gating Control (RCGCUSB), offset 0x628

The **RCGCUSB** register provides software the capability to enable and disable the USB module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the USB module.

Universal Serial Bus Run Mode Clock Gating Control (RCGCUSB)

Base 0x400F.E000
Offset 0x628
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RW	0	USB Module Run Mode Clock Gating Control
		Value	Description	
		0	USB module is disabled.	
		1	Enable and provide a clock to the USB module in Run mode.	

Register 101: Ethernet PHY Run Mode Clock Gating Control (RCGCEPHY), offset 0x630

The **RCGCEPHY** register provides software the capability to enable and disable the PHY module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the PHY module.

Ethernet PHY Run Mode Clock Gating Control (RCGCEPHY)

Base 0x400F.E000
Offset 0x630
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RW	0	Ethernet PHY Module Run Mode Clock Gating Control
		Value	Description	
		0	PHY module is disabled.	
		1	Enable and provide a clock to the PHY module in Run mode.	

Register 102: Controller Area Network Run Mode Clock Gating Control (RCGCCAN), offset 0x634

The **RCGCCAN** register provides software the capability to enable and disable the CAN modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the CAN modules.

Controller Area Network Run Mode Clock Gating Control (RCGCCAN)

Base 0x400F.E000
Offset 0x634
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	R1	RW	0	CAN Module 1 Run Mode Clock Gating Control
		Value	Description	
		0	CAN module 1 is disabled.	
		1	Enable and provide a clock to CAN module 1 in Run mode.	
0	R0	RW	0	CAN Module 0 Run Mode Clock Gating Control
		Value	Description	
		0	CAN module 0 is disabled.	
		1	Enable and provide a clock to CAN module 0 in Run mode.	

Register 103: Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC), offset 0x638

The RCGCADC register provides software the capability to enable and disable the ADC modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the ADC modules.

Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC)

Base 0x400F.E000
Offset 0x638
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	R1	RW	0	ADC Module 1 Run Mode Clock Gating Control
		Value	Description	
		0	ADC module 1 is disabled.	
		1	Enable and provide a clock to ADC module 1 in Run mode.	
0	R0	RW	0	ADC Module 0 Run Mode Clock Gating Control
		Value	Description	
		0	ADC module 0 is disabled.	
		1	Enable and provide a clock to ADC module 0 in Run mode.	

Register 104: Analog Comparator Run Mode Clock Gating Control (RCGCACMP), offset 0x63C

The **RCGCACMP** register provides software the capability to enable and disable the analog comparator module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the analog comparator module.

Analog Comparator Run Mode Clock Gating Control (RCGCACMP)

Base 0x400F.E000
Offset 0x63C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RW	0	Analog Comparator Module 0 Run Mode Clock Gating Control
		Value	Description	
		0	Analog comparator module is disabled.	
		1	Enable and provide a clock to the analog comparator module in Run mode.	

Register 105: Pulse Width Modulator Run Mode Clock Gating Control (RCGCPWM), offset 0x640

The **RCGCPWM** register provides software the capability to enable and disable the PWM modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the PWM modules.

Pulse Width Modulator Run Mode Clock Gating Control (RCGCPWM)

Base 0x400F.E000
Offset 0x640
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RW	0	PWM Module 0 Run Mode Clock Gating Control
		Value	Description	
		0	PWM module 0 is disabled.	
		1	Enable and provide a clock to PWM module 0 in Run mode.	

Register 106: Quadrature Encoder Interface Run Mode Clock Gating Control (RCGCQEI), offset 0x644

The **RCGCQEI** register provides software the capability to enable and disable the QEI modules in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the QEI modules.

Quadrature Encoder Interface Run Mode Clock Gating Control (RCGCQEI)

Base 0x400F.E000
Offset 0x644
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RW	0	QEI Module 0 Run Mode Clock Gating Control
		Value	Description	
		0	QEI module 0 is disabled.	
		1	Enable and provide a clock to QEI module 0 in Run mode.	

Register 107: EEPROM Run Mode Clock Gating Control (RCGCEEPROM), offset 0x658

The **RCGCEEPROM** register provides software the capability to enable and disable the EEPROM module in Run mode. When enabled, the module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

EEPROM Run Mode Clock Gating Control (RCGCEEPROM)

Base 0x400F.E000

Offset 0x658

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RW	0	EEPROM Module 0 Run Mode Clock Gating Control
		Value	Description	
		0	EEPROM module is disabled.	
		1	Enable and provide a clock to the EEPROM module in Run mode.	

Register 108: CRC and Cryptographic Modules Run Mode Clock Gating Control (RCGCCCM), offset 0x674

The **RCGCCCM** register provides software the capability to enable and disable the CRC and Encryption Modules (AES, DES, and SHA/MD5) in Run mode. When enabled, the modules are provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the CRC, AES, DES, and SHA/MD5 modules.

CRC and Cryptographic Modules Run Mode Clock Gating Control (RCGCCCM)

0	R0	RW	0	CRC and Cryptographic Modules Run Mode Clock Gating Control
		Value	Description	
		0	The CRC, AES, DES, and SHA/MD5 modules are disabled.	
		1	Enable and provide a clock to the CRC, AES, DES, and SHA/MD5 modules in Run mode.	

Register 109: LCD Controller Run Mode Clock Gating Control (RCGCLCD), offset 0x690

The **RCGCLCD** register provides software the capability to enable and disable the LCD Controller module in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the LCD Controller module.

LCD Controller Run Mode Clock Gating Control (RCGCLCD)

Base 0x400F.E000
Offset 0x690
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RW	0	LCD Controller Module 0 Run Mode Clock Gating Control
		Value	Description	
		0	LCD Controller module 0 is disabled.	
		1	Enable and provide a clock to LCD Controller module 0 in Run mode.	

Register 110: 1-Wire Run Mode Clock Gating Control (RCGCOWIRE), offset 0x698

The **RCGCOWIRE** register provides software the capability to enable and disable the 1-Wire module in Run mode. When enabled, a module is provided a clock and accesses to module registers are allowed. When disabled, the clock is disabled to save power and accesses to module registers generate a bus fault.

Important: This register should be used to control the clocking for the 1-Wire module.

1-Wire Run Mode Clock Gating Control (RCGCOWIRE)

Base 0x400F.E000
Offset 0x698
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

	0	GPIO Port S is disabled in sleep mode.		
	1	Enable and provide a clock to GPIO Port S in sleep mode.		
15	S15	RW	0	GPIO Port R Sleep Mode Clock Gating Control
	Value Description			
	0	GPIO Port R is disabled in sleep mode.		
	1	Enable and provide a clock to GPIO Port R in sleep mode.		
14	S14	RW	0	GPIO Port Q Sleep Mode Clock Gating Control
	Value Description			
	0	GPIO Port Q is disabled in sleep mode.		
	1	Enable and provide a clock to GPIO Port Q in sleep mode.		

Bit/Field	Name	Type	Reset	Description
13	S13	RW	0	GPIO Port P Sleep Mode Clock Gating Control Value Description 0 GPIO Port P is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port P in sleep mode.
12	S12	RW	0	GPIO Port N Sleep Mode Clock Gating Control Value Description 0 GPIO Port N is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port N in sleep mode.
11	S11	RW	0	GPIO Port M Sleep Mode Clock Gating Control Value Description 0 GPIO Port M is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port M in sleep mode.
10	S10	RW	0	GPIO Port L Sleep Mode Clock Gating Control Value Description 0 GPIO Port L is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port L in sleep mode.
9	S9	RW	0	GPIO Port K Sleep Mode Clock Gating Control Value Description 0 GPIO Port K is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port K in sleep mode.
8	S8	RW	0	GPIO Port J Sleep Mode Clock Gating Control Value Description 0 GPIO Port J is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port J in sleep mode.
7	S7	RW	0	GPIO Port H Sleep Mode Clock Gating Control Value Description 0 GPIO Port H is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port H in sleep mode.

Bit/Field	Name	Type	Reset	Description
6	S6	RW	0	GPIO Port G Sleep Mode Clock Gating Control Value Description 0 GPIO Port G is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port G in sleep mode.
5	S5	RW	0	GPIO Port F Sleep Mode Clock Gating Control Value Description 0 GPIO Port F is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port F in sleep mode.
4	S4	RW	0	GPIO Port E Sleep Mode Clock Gating Control Value Description 0 GPIO Port E is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port E in sleep mode.
3	S3	RW	0	GPIO Port D Sleep Mode Clock Gating Control Value Description 0 GPIO Port D is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port D in sleep mode.
2	S2	RW	0	GPIO Port C Sleep Mode Clock Gating Control Value Description 0 GPIO Port C is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port C in sleep mode.
1	S1	RW	0	GPIO Port B Sleep Mode Clock Gating Control Value Description 0 GPIO Port B is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port B in sleep mode.
0	S0	RW	0	GPIO Port A Sleep Mode Clock Gating Control Value Description 0 GPIO Port A is disabled in sleep mode. 1 Enable and provide a clock to GPIO Port A in sleep mode.

Register 115: Micro Direct Memory Access Sleep Mode Clock Gating Control (SCGCDMA), offset 0x70C

The **SCGCDMA** register provides software the capability to enable and disable the µDMA module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the µDMA module.

Micro Direct Memory Access Sleep Mode Clock Gating Control (SCGCDMA)

Base 0x400F.E000
Offset 0x70C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	S0	RW	0	µDMA Module Sleep Mode Clock Gating Control
		Value	Description	
		0	µDMA module is disabled in sleep mode.	
		1	Enable and provide a clock to the µDMA module in sleep mode.	

Register 116: EPI Sleep Mode Clock Gating Control (SCGCEPI), offset 0x710

The **SCGCEPI** register provides software the capability to enable and disable the EPI module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the EPI module.

EPI Sleep Mode Clock Gating Control (SCGCEPI)

Base 0x400F.E000

Offset 0x710

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	S0	RW	0	EPI Module Sleep Mode Clock Gating Control
		Value	Description	
		0	EPI module is disabled in sleep mode.	
		1	Enable and provide a clock to the EPI module in sleep mode.	

Register 117: Hibernation Sleep Mode Clock Gating Control (SCGCHIB), offset 0x714

The **SCGCHIB** register provides software the capability to enable and disable the Hibernation module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the Hibernation module.

Hibernation Sleep Mode Clock Gating Control (SCGCHIB)

Base 0x400F.E000
Offset 0x714
Type RW, reset 0x0000.0001

31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	S7	RW	0	UART Module 7 Sleep Mode Clock Gating Control
		Value	Description	
		0	UART module 7 is disabled in sleep mode.	
		1	Enable and provide a clock to UART module 7 in sleep mode.	
6	S6	RW	0	UART Module 6 Sleep Mode Clock Gating Control
		Value	Description	
		0	UART module 6 is disabled in sleep mode.	
		1	Enable and provide a clock to UART module 6 in sleep mode.	
5	S5	RW	0	UART Module 5 Sleep Mode Clock Gating Control
		Value	Description	
		0	UART module 5 is disabled in sleep mode.	
		1	Enable and provide a clock to UART module 5 in sleep mode.	
4	S4	RW	0	UART Module 4 Sleep Mode Clock Gating Control
		Value	Description	
		0	UART module 4 is disabled.	
		1	Enable and provide a clock to UART module 4 in sleep mode.	

Bit/Field	Name	Type	Reset	Description
3	S3	RW	0	UART Module 3 Sleep Mode Clock Gating Control Value Description 0 UART module 3 is disabled in sleep mode. 1 Enable and provide a clock to UART module 3 in sleep mode.
2	S2	RW	0	UART Module 2 Sleep Mode Clock Gating Control Value Description 0 UART module 2 is disabled in sleep mode. 1 Enable and provide a clock to UART module 2 in sleep mode.
1	S1	RW	0	UART Module 1 Sleep Mode Clock Gating Control Value Description 0 UART module 1 is disabled in sleep mode. 1 Enable and provide a clock to UART module 1 in sleep mode.
0	S0	RW	0	UART Module 0 Sleep Mode Clock Gating Control Value Description 0 UART module 0 is disabled. 1 Enable and provide a clock to UART module 0 in sleep mode.

Register 119: Synchronous Serial Interface Sleep Mode Clock Gating Control (SCGCSSI), offset 0x71C

The **SCGCSSI** register provides software the capability to enable and disable the SSI modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the SSI modules.

Synchronous Serial Interface Sleep Mode Clock Gating Control (SCGCSSI)

Base 0x400F.E000
Offset 0x71C

0	S0	RW	0	USB Module Sleep Mode Clock Gating Control
		Value	Description	
		0	USB module is disabled in sleep mode.	
		1	Enable and provide a clock to the USB module in sleep mode.	

Register 122: Ethernet PHY Sleep Mode Clock Gating Control (SCGCEPHY), offset 0x730

The **SCGCEPHY** register provides software the capability to enable and disable the PHY module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the PHY module.

Ethernet PHY Sleep Mode Clock Gating Control (SCGCEPHY)

Base 0x400F.E000
Offset 0x730
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	S0	RW	0	PHY Module Sleep Mode Clock Gating Control
		Value	Description	
		0	PHY module is disabled in sleep mode.	
		1	Enable and provide a clock to the PHY module in sleep mode.	

Register 123: Controller Area Network Sleep Mode Clock Gating Control (SCGCCAN), offset 0x734

The **SCGCCAN** register provides software the capability to enable and disable the CAN modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the CAN modules.

Controller Area Network Sleep Mode Clock Gating Control (SCGCCAN)

Base 0x400F.E000
Offset 0x734
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	S1	RW	0	CAN Module 1 Sleep Mode Clock Gating Control
		Value	Description	
	0		CAN module 1 is disabled in sleep mode.	
	1		Enable and provide a clock to CAN module 1 in sleep mode.	
0	S0	RW	0	CAN Module 0 Sleep Mode Clock Gating Control
		Value	Description	
	0		CAN module 0 is disabled.	
	1		Enable and provide a clock to CAN module 0 in sleep mode.	

Register 124: Analog-to-Digital Converter Sleep Mode Clock Gating Control (SCGCADC), offset 0x738

The **SCGCADC** register provides software the capability to enable and disable the ADC modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the ADC modules.

Analog-to-Digital Converter Sleep Mode Clock Gating Control (SCGCADC)

Base 0x400F.E000
Offset 0x738
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description

1	S1	RW	0	ADC Module 1 Sleep Mode Clock Gating Control
				Value Description
			0	ADC module 1 is disabled in sleep mode.
			1	Enable and provide a clock to ADC module 1 in sleep mode.
0	S0	RW	0	ADC Module 0 Sleep Mode Clock Gating Control
				Value Description
			0	ADC module 0 is disabled in sleep mode.
			1	Enable and provide a clock to ADC module 0 in sleep mode.

Register 125: Analog Comparator Sleep Mode Clock Gating Control (SCGCACMP), offset 0x73C

The **SCGCACMP** register provides software the capability to enable and disable the analog comparator module in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the analog comparator module.

Analog Comparator Sleep Mode Clock Gating Control (SCGCACMP)

Base 0x400F.E000
Offset 0x73C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	S0	RW	0	Analog Comparator Module 0 Sleep Mode Clock Gating Control
		Value	Description	
		0	Analog comparator module is disabled in sleep mode.	
		1	Enable and provide a clock to the analog comparator module in sleep mode.	

Register 126: Pulse Width Modulator Sleep Mode Clock Gating Control (SCGCPWM), offset 0x740

The **SCGCPWM** register provides software the capability to enable and disable the PWM modules in sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the PWM modules.

Pulse Width Modulator Sleep Mode Clock Gating Control (SCGCPWM)

Base 0x400F.E000
Offset 0x740
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description

		Value	Description	
	0	0	ADC module 0 is disabled in deep-sleep mode.	
	1	1	Enable and provide a clock to ADC module 0 in deep-sleep mode.	

Register 146: Analog Comparator Deep-Sleep Mode Clock Gating Control (DCGCACMP), offset 0x83C

The DCGCACMP register provides software the capability to enable and disable the analog comparator module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the analog comparator module.

Analog Comparator Deep-Sleep Mode Clock Gating Control (DCGCACMP)

Base 0x400F.E000
Offset 0x83C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	D0	RW	0	Analog Comparator Module 0 Deep-Sleep Mode Clock Gating Control
		Value	Description	
		0	Analog comparator module is disabled in deep-sleep mode.	
		1	Enable and provide a clock to the analog comparator module in deep-sleep mode.	

Register 147: Pulse Width Modulator Deep-Sleep Mode Clock Gating Control (DCGCPWM), offset 0x840

The **DCGCPWM** register provides software the capability to enable and disable the PWM modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the PWM modules.

Pulse Width Modulator Deep-Sleep Mode Clock Gating Control (DCGCPWM)

Base 0x400F.E000
Offset 0x840
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	D0	RW	0	PWM Module 0 Deep-Sleep Mode Clock Gating Control
		Value	Description	
		0	PWM module 0 is disabled in deep-sleep mode.	
		1	Enable and provide a clock to PWM module 0 in deep-sleep mode.	

Register 148: Quadrature Encoder Interface Deep-Sleep Mode Clock Gating Control (DCGCQEI), offset 0x844

The **DCGCQEI** register provides software the capability to enable and disable the QEI modules in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the QEI modules.

Quadrature Encoder Interface Deep-Sleep Mode Clock Gating Control (DCGCQEI)

Base 0x400F.E000
Offset 0x844
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	D0	RW	0	QEI Module 0 Deep-Sleep Mode Clock Gating Control
		Value	Description	
		0	QEI module 0 is disabled in deep-sleep mode.	
		1	Enable and provide a clock to QEI module 0 in deep-sleep mode.	

Register 149: EEPROM Deep-Sleep Mode Clock Gating Control (DCGCEEPROM), offset 0x858

The **DCGCEEEPROM** register provides software the capability to enable and disable the EEPROM module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

EEPROM Deep-Sleep Mode Clock Gating Control (DCGCEEEPROM)

Base 0x400F.E000

Offset 0x858

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	D0	RW	0	EEPROM Module 0 Deep-Sleep Mode Clock Gating Control
		Value	Description	
		0	EEPROM module is disabled in deep-sleep mode.	
		1	Enable and provide a clock to the EEPROM module in deep-sleep mode.	

Register 150: CRC and Cryptographic Modules Deep-Sleep Mode Clock Gating Control (DCGCCCM), offset 0x874

The **DCGCCCM** register provides software the capability to enable and disable the CRC, AES, DES, and SHA/MD5 modules in deep-sleep mode. When enabled, the modules are provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the CRC, AES, DES, and SHA/MD5 modules.

CRC and Cryptographic Modules Deep-Sleep Mode Clock Gating Control (DCGCCCM)

Base 0x400F.E000
Offset 0x874
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	D0	RW	0	CRC and Cryptographic Modules Deep-Sleep Mode Clock Gating Control

Value	Description
0	The CRC, AES, DES, and SHA/MD5 modules are disabled in deep-sleep mode.
1	Enable and provide a clock to the CRC, AES, DES, and SHA/MD5 modules in deep-sleep mode.

Register 151: LCD Controller Deep-Sleep Mode Clock Gating Control (DCGCLCD), offset 0x890

The **DCGCLCD** register provides software the capability to enable and disable the LCD Controller module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the LCD Controller module.

LCD Controller Deep-Sleep Mode Clock Gating Control (DCGCLCD)

Base 0x400F.E000
Offset 0x890

0	D0	RW	0	LCD Controller Module 0 Deep-Sleep Mode Clock Gating Control
				Value Description
			0	LCD Controller module 0 is disabled in deep-sleep mode.
			1	Enable and provide a clock to LCD Controller module 0 in deep-sleep mode.

Register 152: 1-Wire Deep-Sleep Mode Clock Gating Control (DCGCOWIRE), offset 0x898

The **DCGCOWIRE** register provides software the capability to enable and disable the 1-Wire module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the 1-Wire module.

1-Wire Deep-Sleep Mode Clock Gating Control (DCGCOWIRE)

Base 0x400F.E000
Offset 0x898
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	D0	RW	0	1-Wire Module 0 Deep-Sleep Mode Clock Gating Control
		Value	Description	
		0	1-Wire module 0 is disabled in deep-sleep mode.	
		1	Enable and provide a clock to 1-Wire module 0 in deep-sleep mode.	

Register 153: Ethernet MAC Deep-Sleep Mode Clock Gating Control (DCGCEMAC), offset 0x89C

The **DCGCEMAC** register provides software the capability to enable and disable the Ethernet MAC module in deep-sleep mode. When enabled, a module is provided a clock. When disabled, the clock is disabled to save power.

Important: This register should be used to control the clocking for the Ethernet MAC module.

Ethernet MAC Deep-Sleep Mode Clock Gating Control (DCGCEMAC)

Base 0x400F.E000
Offset 0x89C
Type RW, reset 0x0000.0000

Type	RO	RW														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	D0	RW	0	Ethernet MAC Module 0 Deep-Sleep Mode Clock Gating Control
		Value	Description	
		0	Ethernet MAC module 0 is disabled in deep-sleep mode.	
		1	Enable and provide a clock to Ethernet MAC module 0 in deep-sleep mode.	

Register 154: Watchdog Timer Power Control (PCWD), offset 0x900

Important: The Watchdog Timer modules do not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCWD** register controls the power applied to the Watchdog Module module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCWD**, **SCGCWD** and **DCGCWD** registers. If the Rn, Sn, or Dn bit of the respective **RCGCWD**, **SCGCWD** and **DCGCWD** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCWD** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCWD**, **SCGCWD** and **DCGCWD** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCWD** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-16. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

Watchdog Timer Power Control (PCWD)

Base 0x400F.E000
Offset 0x900

In this case, the module is inactive.
Value	Description									
0	Watchdog Timer 0 module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.									
1	Watchdog Timer 0 module is powered, but does not receive a clock. In this case, the module is inactive.									

Register 155: 16/32-Bit General-Purpose Timer Power Control (PCTIMER), offset 0x904

Important: The Timer module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCTIMER** register controls the power applied to the Timer module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCTIMER**, **SCGCTIMER** and **DCGCTIMER** registers. If the R_n, S_n, or D_n bit of the respective **RCGCTIMER**, **SCGCTIMER** and **DCGCTIMER** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCTIMER** register is.

However, if the R_n, S_n, or D_n bit of the respective **RCGCTIMER**, **SCGCTIMER** and **DCGCTIMER** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding P_n bit in the **PCTIMER** register. In this case, when the P_n bit is clear the module is not powered and does not receive a clock. If the P_n bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-17. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

1	Timer 0 module is powered, but does not receive a clock. In this case, the module is inactive.									

Register 156: General-Purpose Input/Output Power Control (PCGPIO), offset 0x908

Important: The GPIO modules do not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCGPIO** register controls the power applied to the GPIO module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCGPIO**, **SCGCGPIO** and **DCGCGPIO** registers. If the Rn, Sn, or Dn bit of the respective **RCGCGPIO**, **SCGCGPIO** and **DCGCGPIO** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCGPIO** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCGPIO**, **SCGCGPIO** and **DCGCGPIO** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCGPIO** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-18. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

1	GPIO Port A is powered, but does not receive a clock. In this case, the module is inactive.									

Register 157: Micro Direct Memory Access Power Control (PCDMA), offset 0x90C

Important: The μDMA module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCDMA** register controls the power applied to the DMA module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCDMA**, **SCGCDMA** and **DCGCDMA** registers. If the R_n, S_n, or D_n bit of the respective **RCGCDMA**, **SCGCDMA** and **DCGCDMA** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCDMA** register is.

However, if the R_n, S_n, or D_n bit of the respective **RCGCDMA**, **SCGCDMA** and **DCGCDMA** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding P_n bit in the **PCDMA** register. In this case, when the P_n bit is clear the module is not powered and does not receive a clock. If the P_n bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-19. Module Power Control

R _n , S _n or D _n Value in Respective RCGCx, SCGCx, or DCGCx Register	P _n	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGcx, SCGcx, or DCGcx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

Micro Direct Memory Access Power Control (PCDMA)

Base 0x400F.E000
Offset 0x90C
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description						
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
0	P0	RW	1	<p>μDMA Module Power Control</p> <p>The Pn bit encodings are not applicable if the corresponding bit in the RCGCDMA, SCGCDMA or DCGCDMA register is clear.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td> <p>The μDMA module is not powered and does not receive a clock. In this case, the module's state is not retained.</p> <p>This configuration provides the lowest power consumption state.</p> </td></tr> <tr> <td>1</td><td>The μDMA module is powered, but does not receive a clock. In this case, the module is inactive.</td></tr> </tbody> </table>	Value	Description	0	<p>The μDMA module is not powered and does not receive a clock. In this case, the module's state is not retained.</p> <p>This configuration provides the lowest power consumption state.</p>	1	The μDMA module is powered, but does not receive a clock. In this case, the module is inactive.
Value	Description									
0	<p>The μDMA module is not powered and does not receive a clock. In this case, the module's state is not retained.</p> <p>This configuration provides the lowest power consumption state.</p>									
1	The μDMA module is powered, but does not receive a clock. In this case, the module is inactive.									

Register 158: External Peripheral Interface Power Control (PCEPI), offset 0x910

Important: The EPI module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCEPI** register controls the power applied to the EPI module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCEPI**, **SCGCEPI** and **DCGCEPI** registers. If the R_n, S_n, or D_n bit of the respective **RCGCEPI**, **SCGCEPI** and **DCGCEPI** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCEPI** register is.

However, if the R_n, S_n, or D_n bit of the respective **RCGCEPI**, **SCGCEPI** and **DCGCEPI** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding P_n bit in the **PCEPI** register. In this case, when the P_n bit is clear the module is not powered and does not receive a clock. If the P_n bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-20. Module Power Control

R _n , S _n or D _n Value in Respective RCGCx, SCGCx, or DCGCx Register	P _n	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

External Peripheral Interface Power Control (PCEPI)

Base 0x400F.E000
Offset 0x910
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description				
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
0	P0	RW	1	EPI Module Power Control The Pn bit encodings are not applicable if the corresponding bit in the RCGCEPI , SCGCEPI or DCGCEPI register is clear.				
Value Description								
<table border="0"> <tr> <td style="vertical-align: top; padding-right: 10px;">0</td> <td>The EPI module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.</td> </tr> <tr> <td style="vertical-align: top;">1</td> <td>The EPI module is powered, but does not receive a clock. In this case, the module is inactive.</td> </tr> </table>					0	The EPI module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.	1	The EPI module is powered, but does not receive a clock. In this case, the module is inactive.
0	The EPI module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.							
1	The EPI module is powered, but does not receive a clock. In this case, the module is inactive.							

Register 159: Hibernation Power Control (PCHIB), offset 0x914

Important: The Hibernation module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCHIB** register controls the power applied to the HIB module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCHIB**, **SCGCHIB** and **DCGCHIB** registers. If the Rn, Sn, or Dn bit of the respective **RCGCHIB**, **SCGCHIB** and **DCGCHIB** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCHIB** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCHIB**, **SCGCHIB** and **DCGCHIB** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCHIB** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-21. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

Hibernation Power Control (PCHIB)

Base 0x400F.E000
Offset 0x914
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	P0	RW	1	Hibernation Module Power Control The Pn bit encodings are not applicable if the corresponding bit in the RCGCHIB , SCGCHIB or DCGCHIB register is clear.
Value Description				
0 The HIB module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 The HIB module is powered, but does not receive a clock. In this case, the module is inactive.				

Register 160: Universal Asynchronous Receiver/Transmitter Power Control (PCUART), offset 0x918

Important: The UART module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCUART** register controls the power applied to the UART module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCUART**, **SCGCUART** and **DCGCUART** registers. If the **Rn**, **Sn**, or **Dn** bit of the respective **RCGCUART**, **SCGCUART** and **DCGCUART** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding **Pn** bit in the **PCUART** register is.

However, if the **Rn**, **Sn**, or **Dn** bit of the respective **RCGCUART**, **SCGCUART** and **DCGCUART** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding **Pn** bit in the **PCUART** register. In this case, when the **Pn** bit is clear the module is not powered and does not receive a clock. If the **Pn** bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-22. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGcx, SCGcx, or DCGcx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>

Register 163: Universal Serial Bus Power Control (PCUSB), offset 0x928

The **PCUSB** register controls the power applied to the USB module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCUSB**, **SCGCUSB** and **DCGCUSB** registers. If the R_n, S_n, or D_n bit of the respective **RCGCUSB**, **SCGCUSB** and **DCGCUSB** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCUSB** register is.

However, if the R_n, S_n, or D_n bit of the respective **RCGCUSB**, **SCGCUSB** and **DCGCUSB** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding P_n bit in the **PCUSB** register. In this case, when the P_n bit is clear the module is not powered and does not receive a clock. If the P_n bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-25. Module Power Control

R _n , S _n or D _n Value in Respective RCGCx, SCGCx, or DCGCx Register	P _n	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P₀ bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

Universal Serial Bus Power Control (PCUSB)

Base 0x400F.E000
Offset 0x928
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	P0	RW	1	USB Module Power Control The P_n bit encodings are not applicable if the corresponding bit in the RCCGUSB , SCGCUSB or DCCGUSB register is clear.
Value Description				
0 The USB module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 The USB module is powered, but does not receive a clock. In this case, the module is inactive.				

Register 164: Ethernet PHY Power Control (PCEPHY), offset 0x930

The **PCEPHY** register controls the power applied to the EEPROM module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCEPHY**, **SCGCEPHY** and **DCGCEPHY** registers. If the R_n, S_n, or D_n bit of the respective **RCGCEPHY**, **SCGCEPHY** and **DCGCEPHY** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCEPHY** register is.

However, if the R_n, S_n, or D_n bit of the respective **RCGCEPHY**, **SCGCEPHY** and **DCGCEPHY** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding P_n bit in the **PCEPHY** register. In this case, when the P_n bit is clear the module is not powered and does not receive a clock. If the P_n bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-26. Module Power Control

R _n , S _n or D _n Value in Respective RCGCx, SCGCx, or DCGCx Register	P _n	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

Note: The Ethernet PHY module is not powered up at reset to prevent an automatic negotiation on power-up. To properly initialize the PHY, first inhibit the PHY from running on power up by setting the PHYHOLD bit in the **Ethernet Peripheral Configuration (EMACPC)** register and then set the P0 bit in the **PCEPHY** register. Once it is determined that the PHY is ready (by polling the R0 bit in the **Peripheral Ready (PREPHY)** register), the PHY can be programmed with its appropriate values.

Note: If the MOSC is chosen as the clock to the Ethernet PHY then software has to enable the MOSC before enabling the Ethernet PHY by setting the P0 bit in the **PCEPHY**.

Ethernet PHY Power Control (PCEPHY)

Base 0x400F.E000
Offset 0x930
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description				
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
0	P0	RW	0	Ethernet PHY Module Power Control The P_n bit encodings are not applicable if the corresponding bit in the RCGCEPHY , SCGCEPHY or DCCGCEPHY register is clear.				
Value Description								
<table><tbody><tr><td>0</td><td>The EPHY module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.</td></tr><tr><td>1</td><td>The EPHY module is powered, but does not receive a clock. In this case, the module is inactive.</td></tr></tbody></table>					0	The EPHY module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.	1	The EPHY module is powered, but does not receive a clock. In this case, the module is inactive.
0	The EPHY module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.							
1	The EPHY module is powered, but does not receive a clock. In this case, the module is inactive.							

Register 165: Controller Area Network Power Control (PCCAN), offset 0x934

The **PCCAN** register controls the power applied to the CAN module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCCAN**, **SCGCCAN** and **DCGCCAN** registers. If the R_n, S_n, or D_n bit of the respective **RCGCCAN**, **SCGCCAN** and **DCGCCAN** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCCAN** register is.

However, if the R_n, S_n, or D_n bit of the respective **RCGCCAN**, **SCGCCAN** and **DCGCCAN** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding P_n bit in the **PCCAN** register. In this case, when the P_n bit is clear the module is not powered and does not receive a clock. If the P_n bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-27. Module Power Control

R _n , S _n or D _n Value in Respective RCGCx, SCGCx, or DCGCx Register	P _n	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P₀ bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>

1	The CAN module 0 is powered, but does not receive a clock. In this case, the module is inactive.									

Register 166: Analog-to-Digital Converter Power Control (PCADC), offset 0x938

Important: The ADC module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCADC** register controls the power applied to the ADC module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCADC**, **SCGCADC** and **DCGCADC** registers. If the R_n, S_n, or D_n bit of the respective **RCGCADC**, **SCGCADC** and **DCGCADC** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCADC** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCADC**, **SCGCADC** and **DCGCADC** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCADC** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-28. Module Power Control

Register 167: Analog Comparator Power Control (PCACMP), offset 0x93C

Important: The ACMP module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCACMP** register controls the power applied to the ACMP module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCACMP**, **SCGCACMP** and **DCCGACMP** registers. If the Rn, Sn, or Dn bit of the respective **RCGCACMP**, **SCGCACMP** and **DCCGACMP** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCACMP** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCACMP**, **SCGCACMP** and **DCCGACMP** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCACMP** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-29. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCCGx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCCGx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

Analog Comparator Power Control (PCACMP)

Base 0x400F.E000
Offset 0x93C
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	P0	RW	1	Analog Comparator Module 0 Power Control The Pn bit encodings are not applicable if the corresponding bit in the RCGCACMP , SCGCACMP or DCCGACMP register is clear.
Value Description				
0 The Analog Comparator module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 The Analog Comparator module is powered, but does not receive a clock. In this case, the module is inactive.				

Register 168: Pulse Width Modulator Power Control (PCPWM), offset 0x940

Important: The PWM module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCPWM** register controls the power applied to the PWM module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCPWM**, **SCGCPWM** and **DCGCPWM** registers. If the Rn, Sn, or Dn bit of the respective **RCGCPWM**, **SCGCPWM** and **DCGCPWM** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCPWM** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCPWM**, **SCGCPWM** and **DCGCPWM** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCPWM** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-30. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCCGx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

Pulse Width Modulator Power Control (PCPWM)

Base 0x400F.E000
Offset 0x940
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	P0	RW	1	PWM Module 0 Power Control The P_n bit encodings are not applicable if the corresponding bit in the RCGCPWM , SCGCPWM or DCGCPWM register is clear.
Value Description				
0 The PWM module 0 is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 The PWM module 0 is powered, but does not receive a clock. In this case, the module is inactive.				

Register 169: Quadrature Encoder Interface Power Control (PCQEI), offset 0x944

Important: The QEI module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCQEI** register controls the power applied to the QEI module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCQEI**, **SCGCQEI** and **DCGCQEI** registers. If the Rn, Sn, or Dn bit of the respective **RCGCQEI**, **SCGCQEI** and **DCGCQEI** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCQEI** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCQEI**, **SCGCQEI** and **DCGCQEI** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCQEI** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-31. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

Quadrature Encoder Interface Power Control (PCQEI)

Base 0x400F.E000
Offset 0x944
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	P0	RW	1	QEI Module 0 Power Control The P_n bit encodings are not applicable if the corresponding bit in the RCGCQEI , SCGCQEI or DCCGCQEI register is clear.
Value Description				
0 QEI module 0 is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 QEI module 0 is powered, but does not receive a clock. In this case, the module is inactive.				

Register 170: EEPROM Power Control (PCEEPROM), offset 0x958

Important: The EEPROM module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCEEPROM** register controls the power applied to the EEPROM module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCEEPROM**, **SCGCEEPROM** and **DCGCEEPROM** registers. If the Rn, Sn, or Dn bit of the respective **RCGCEEPROM**, **SCGCEEPROM** and **DCGCEEPROM** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCEEPROM** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCEEPROM**, **SCGCEEPROM** and **DCGCEEPROM** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCEEPROM** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-32. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

EEPROM Power Control (PCEEPROM)

Base 0x400F.E000
Offset 0x958
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	P0	RW	1	EEPROM Module 0 Power Control The P_n bit encodings are not applicable if the corresponding bit in the RCGCEEPROM , SCGCEEPROM or DCGCEEPROM register is clear.
Value Description				
0 The EEPROM module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 The EEPROM module is powered, but does not receive a clock. In this case, the module is inactive.				

Register 171: CRC and Cryptographic Modules Power Control (PCCCM), offset 0x974

The **PCCCM** register controls the power applied to the CRC and AES, DES, and SHA/MD5 modules. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCCC**M, **SCGCC**M and **DCGCC**M registers. If the R_n, S_n, or D_n bit of the respective **RCGCCC**M, **SCGCC**M and **DCGCC**M registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCCCM** register is.

However, if the R_n, S_n, or D_n bit of the respective **RCGCCC**M, **SCGCC**M and **DCGCC**M registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding P_n bit in the **PCCCM** register. In this case, when the P_n bit is clear the module is not powered and does not receive a clock. If the P_n bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-33. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

CRC and Cryptographic Modules Power Control (PCCCM)

Base 0x400F.E000

Offset 0x974

Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	P0	RW	1	CRC and Cryptographic Modules Power Control The P_n bit encodings are not applicable if the corresponding bit in the RCGCCCCM , SCGCCCCM or DCGCCCCM register is clear.
Value Description				
0 The CRC, AES, DES, and SHA/MD5 modules are not powered and do not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 The CRC, AES, DES, and SHA/MD5 modules are powered, but do not receive a clock. In this case, the modules are inactive.				

Register 172: LCD Controller Power Control (PCLCD), offset 0x990

The **PCLCD** register controls the power applied to the LCD module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCLCD**, **SCGCLCD** and **DCGCLCD** registers. If the Rn, Sn, or Dn bit of the respective **RCGCLCD**, **SCGCLCD** and **DCGCLCD** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding Pn bit in the **PCLCD** register is.

However, if the Rn, Sn, or Dn bit of the respective **RCGCLCD**, **SCGCLCD** and **DCGCLCD** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding Pn bit in the **PCLCD** register. In this case, when the Pn bit is clear the module is not powered and does not receive a clock. If the Pn bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-34. Module Power Control

Rn, Sn or Dn Value in Respective RCGCx, SCGCx, or DCGCx Register	Pn	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

LCD Controller Power Control (PCLCD)

Base 0x400F.E000

Offset 0x990

Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	P0	RW	1	LCD Controller Module 0 Power Control The Pn bit encodings are not applicable if the corresponding bit in the RCGCLCD , SCGCLCD or DCGCLCD register is clear.
Value Description				
0 LCD module 0 is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 LCD module 0 is powered, but does not receive a clock. In this case, the module is inactive.				

Register 173: 1-Wire Power Control (PCOWIRE), offset 0x998

Important: The 1-Wire module does not currently provide the ability to respond to the power down request. Setting a bit in this register has no effect on power consumption. This register is defined for future software compatibility.

The **PCOWIRE** register controls the power applied to the 1-Wire module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCOWIRE**, **SCGCOWIRE** and **DCGCOWIRE** registers. If the R_n, S_n, or D_n bit of the respective **RCGCOWIRE**, **SCGCOWIRE** and **DCGCOWIRE** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCOWIRE** register is.

However, if the R_n, S_n, or D_n bit of the respective **RCGCOWIRE**, **SCGCOWIRE** and **DCGCOWIRE** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding P_n bit in the **PCOWIRE** register. In this case, when the P_n bit is clear the module is not powered and does not receive a clock. If the P_n bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-35. Module Power Control

R _n , S _n or D _n Value in Respective RCGCx, SCGCx, or DCGCx Register	P _n	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P0 bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

1-Wire Power Control (PCOWIRE)

Base 0x400F.E000
Offset 0x998
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	P0	RW	1	1-Wire Module 0 Power Control The P_n bit encodings are not applicable if the corresponding bit in the RCGCOWIRE , SCGCOWIRE or DCGCOWIRE register is clear.
Value Description				
0 The 1-Wire module is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 The 1-Wire module is powered, but does not receive a clock. In this case, the module is inactive.				

Register 174: Ethernet MAC Power Control (PCEMAC), offset 0x99C

The **PCEMAC** register controls the power applied to the EMAC module. The function of this bit depends on the current state of the device (Run, Sleep or Deep-Sleep mode) and value of the corresponding bits in the **RCGCEMAC**, **SCGCEMAC** and **DCGCEMAC** registers. If the R_n, S_n, or D_n bit of the respective **RCGCEMAC**, **SCGCEMAC** and **DCGCEMAC** registers is 1 and the device is in that mode, the module is powered and receives a clock irrespective of what the corresponding P_n bit in the **PCEMAC** register is.

However, if the R_n, S_n, or D_n bit of the respective **RCGCEMAC**, **SCGCEMAC** and **DCGCEMAC** registers is 0 and the device is in that mode, then the module behaves differently depending on the value of the corresponding P_n bit in the **PCEMAC** register. In this case, when the P_n bit is clear the module is not powered and does not receive a clock. If the P_n bit is set, the module is powered but does not receive a clock. The table below details the differences.

Table 5-36. Module Power Control

R _n , S _n or D _n Value in Respective RCGCx, SCGCx, or DCGCx Register	P _n	Description
0	0	<p>Module is not powered and does not receive a clock. In this case, the peripheral's state is not retained.</p> <p>This is the lowest power consumption state of any peripheral since it consumes no dynamic nor leakage current. Hardware should perform a peripheral reset if the active mode changes and the RCGCx, SCGCx, or DCGCx register is a 1 or the P₀ bit is changed to a 1.</p> <p>Software must re-initialize the peripheral when re-enabled due to the loss of state.</p>
0	1	<p>Module is powered, but does not receive a clock.</p> <p>In this case, the peripheral is inactive. This is the second-lowest power consumption of any peripheral since it consumes only leakage current.</p>
1	X	Module is powered and receives a clock.

Ethernet MAC Power Control (PCEMAC)

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	P0	RW	1	Ethernet MAC Module 0 Power Control The Pn bit encodings are not applicable if the corresponding bit in the RCGCEMAC , SCGCEMAC or DCGCEMAC register is clear.
Value Description				
0 Ethernet MAC Module 0 is not powered and does not receive a clock. In this case, the module's state is not retained. This configuration provides the lowest power consumption state.				
1 Ethernet MAC module 0 is powered, but does not receive a clock. In this case, the module is inactive.				

Register 175: Watchdog Timer Peripheral Ready (PRWD), offset 0xA00

The **PRWD** register indicates whether the watchdog modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCWD** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCWD** bit is changed. A reset change is initiated if the corresponding **SRWD** bit is changed from 0 to 1.

The **PRWD** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

		Value	Description	
		0	GPIO Port R is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence.	
		1	GPIO Port R is ready for access.	

Bit/Field	Name	Type	Reset	Description
14	R14	RO	0	GPIO Port Q Peripheral Ready Value Description 0 GPIO Port Q is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port Q is ready for access.
13	R13	RO	0	GPIO Port P Peripheral Ready Value Description 0 GPIO Port P is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port P is ready for access.
12	R12	RO	0	GPIO Port N Peripheral Ready Value Description 0 GPIO Port N is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port N is ready for access.
11	R11	RO	0	GPIO Port M Peripheral Ready Value Description 0 GPIO Port M is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port M is ready for access.
10	R10	RO	0	GPIO Port L Peripheral Ready Value Description 0 GPIO Port L is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port L is ready for access.
9	R9	RO	0	GPIO Port K Peripheral Ready Value Description 0 GPIO Port K is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port K is ready for access.
8	R8	RO	0	GPIO Port J Peripheral Ready Value Description 0 GPIO Port J is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port J is ready for access.

Bit/Field	Name	Type	Reset	Description
7	R7	RO	0	GPIO Port H Peripheral Ready Value Description 0 GPIO Port H is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port H is ready for access.
6	R6	RO	0	GPIO Port G Peripheral Ready Value Description 0 GPIO Port G is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port G is ready for access.
5	R5	RO	0	GPIO Port F Peripheral Ready Value Description 0 GPIO Port F is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port F is ready for access.
4	R4	RO	0	GPIO Port E Peripheral Ready Value Description 0 GPIO Port E is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port E is ready for access.
3	R3	RO	0	GPIO Port D Peripheral Ready Value Description 0 GPIO Port D is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port D is ready for access.
2	R2	RO	0	GPIO Port C Peripheral Ready Value Description 0 GPIO Port C is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port C is ready for access.
1	R1	RO	0	GPIO Port B Peripheral Ready Value Description 0 GPIO Port B is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence. 1 GPIO Port B is ready for access.

Bit/Field	Name	Type	Reset	Description
0	R0	RO	0	GPIO Port A Peripheral Ready
Value Description				
		0		GPIO Port A is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence.
		1		GPIO Port A is ready for access.

Register 178: Micro Direct Memory Access Peripheral Ready (PRDMA), offset 0xA0C

The **PRDMA** register indicates whether the µDMA module is ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCDMA** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCDMA** bit is changed. A reset change is initiated if the corresponding **SRDMA** bit is changed from 0 to 1.

The **PRDMA** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

Micro Direct Memory Access Peripheral Ready (PRDMA)

Base 0x400F.E000

Offset 0xA0C

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RO	0	µDMA Module Peripheral Ready
		Value	Description	
		0	The µDMA module is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence.	
		1	The µDMA module is ready for access.	

Register 179: EPI Peripheral Ready (PREPI), offset 0xA10

The **PREPI** register indicates whether the EPI module is ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCEPI** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCEPI** bit is changed. A reset change is initiated if the corresponding **SREPI** bit is changed from 0 to 1.

The **PREPI** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RO	0	PWM Module 0 Peripheral Ready

Value	Description
0	PWM module 0 is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence.
1	PWM module 0 is ready for access.

Register 190: Quadrature Encoder Interface Peripheral Ready (PRQEI), offset 0xA44

The **PRQEI** register indicates whether the QEI modules are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCQEI** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCQEI** bit is changed. A reset change is initiated if the corresponding **SRQEI** bit is changed from 0 to 1.

The **PRQEI** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

Quadrature Encoder Interface Peripheral Ready (PRQEI)

Base 0x400F.E000

Offset 0xA44

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	R0	RO	0	QEI Module 0 Peripheral Ready
		Value	Description	
		0	QEI module 0 is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence.	
		1	QEI module 0 is ready for access.	

Register 191: EEPROM Peripheral Ready (PREEPROM), offset 0xA58

The **PREEPROM** register indicates whether the EEPROM module is ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCEEEPROM** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCEEEPROM** bit is changed. A reset change is initiated if the corresponding **SREEEEPROM** bit is changed from 0 to 1.

The **PREEPROM** bit is cleared on any of the above events and is not set again until the module is completely powered, enabled, and internally reset.

0	R0	RO	0	EEPROM Module 0 Peripheral Ready

Value	Description
0	The EEPROM module is not ready for access. It is unclocked, unpowered, or in the process of completing a reset sequence.
1	The EEPROM module is ready for access.

Register 192: CRC and Cryptographic Modules Peripheral Ready (PRCCM), offset 0xA74

The **PRCCM** register indicates whether the CRC and Cryptographic Modules(AES, DES, and SHA/MD5) are ready to be accessed by software following a change in status of power, Run mode clocking, or reset. A power change is initiated if the corresponding **PCCCM** bit is changed from 0 to 1. A Run mode clocking change is initiated if the corresponding **RCGCCCCM** bit is changed. A reset change is initiated if the corresponding **SRCCM** bit is changed from 0 to 1.

The **PRCCM** bit is cleared on any of the above events and is not set again until the modules are completely powered, enabled, and internally reset.

5.6 Cryptographic System Control Register Description (CCM Offset)

This section lists and describes the system control registers for the CRC and Cryptographic (AES, DES, SHA) Modules. Registers in this section are relative to the CCM base address of 0x4403.0000.

Register 196: Cryptographic Modules Clock Gating Request (CCMCGREQ), offset 0x204

The **Cryptographic Modules Clock Gating Request (CCMCGREQ)** register is written to enable or disable clock gating in the AES, DES, and SHA/MD5 Module.

Cryptographic Modules Clock Gating Request (CCMCGREQ)

Base 0x400F.E000
Offset 0x204
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RW	0x00000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	DESCFCFG	RW	0	DES Clock Gating Request
		Value	Description	
		0	Request to un-gate clock gating	
		1	Request to gate the clock.	
1	AESCFG	RW	0	AES Clock Gating Request
		Value	Description	
		0	Request to un-gate clock gating	
		1	Request to gate the clock.	
0	SHACFG	RW	0	SHA/MD5 Clock Gating Request
		Value	Description	
		0	Request to un-gate clock gating	
		1	Request to gate the clock.	

6 Processor Support and Exception Module

This module is an AHB peripheral that handles system-level Cortex-M4 FPU exceptions. For functions with registers mapped into this aperture, if the function is not available on a device, then all writes to the associated registers are ignored and reads return zeros.

6.1 Functional Description

The System Exception module provides control and status of the system-level interrupts. All the interrupt events are ORed together before being sent to the interrupt controller, so the System Exception module can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **System Exception Masked Interrupt Status (SYSEXCMS)** register. The interrupt events that can trigger a controller-level interrupt are defined in the **System Exception Interrupt Mask (SYSEXCM)** register by setting the corresponding interrupt mask bits. If interrupts are not used, the raw interrupt status is always visible via the **System Exception Raw Interrupt Status (SYSEXCRIS)** register. Interrupts are always cleared (for both the **SYSEXCMS** and **SYSEXCRIS** registers) by writing a 1 to the corresponding bit in the **System Exception Interrupt Clear (SYSEXCIC)** register.

6.2 Register Map

Table 6-1 on page 553 lists the System Exception module registers. The offset listed is a hexadecimal increment to the register's address, relative to the System Exception base address of 0x400F.9000.

Note: Spaces in the System Exception register space that are not used are reserved for future or internal use. Software should not modify any reserved memory address.

Table 6-1. System Exception Register Map

Offset	Name	Type	Reset	Description	See page
0x000	SYSEXCRIS	RO	0x0000.0000	System Exception Raw Interrupt Status	554
0x004	SYSEXCMIM	RW	0x0000.0000	System Exception Interrupt Mask	556
0x008	SYSEXCMS	RO	0x0000.0000	System Exception Masked Interrupt Status	558
0x00C	SYSEXCIC	W1C	0x0000.0000	System Exception Interrupt Clear	560

6.3 Register Descriptions

All addresses given are relative to the System Exception base address of 0x400F.9000.

Register 1: System Exception Raw Interrupt Status (SYSEXCRIS), offset 0x000

The **SYSEXCRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt. A write has no effect.

System Exception Raw Interrupt Status (SYSEXCRIS)

Base 0x400F.9000
Offset 0x000
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	FPIXCRIS	RO	0	Floating-Point Inexact Exception Raw Interrupt Status Value Description 0 No interrupt 1 A floating-point inexact exception has occurred. This bit is cleared by writing a 1 to the IXCIC bit in the SYSEXIC register.
4	FPOFCRIS	RO	0	Floating-Point Overflow Exception Raw Interrupt Status Value Description 0 No interrupt 1 A floating-point overflow exception has occurred. This bit is cleared by writing a 1 to the OFCIC bit in the SYSEXIC register.
3	FPUFCRIS	RO	0	Floating-Point Underflow Exception Raw Interrupt Status Value Description 0 No interrupt 1 A floating-point underflow exception has occurred. This bit is cleared by writing a 1 to the UFCIC bit in the SYSEXIC register.

Bit/Field	Name	Type	Reset	Description						
2	FPIOCRIS	RO	0	<p>Floating-Point Invalid Operation Raw Interrupt Status</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No interrupt</td></tr> <tr> <td>1</td><td>A floating-point invalid operation exception has occurred.</td></tr> </tbody> </table> <p>This bit is cleared by writing a 1 to the IOCIC bit in the SYSEXCIC register.</p>	Value	Description	0	No interrupt	1	A floating-point invalid operation exception has occurred.
Value	Description									
0	No interrupt									
1	A floating-point invalid operation exception has occurred.									
1	FPDZCRIS	RO	0	<p>Floating-Point Divide By 0 Exception Raw Interrupt Status</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No interrupt</td></tr> <tr> <td>1</td><td>A floating-point divide by 0 exception has occurred.</td></tr> </tbody> </table> <p>This bit is cleared by writing a 1 to the DZCIC bit in the SYSEXCIC register.</p>	Value	Description	0	No interrupt	1	A floating-point divide by 0 exception has occurred.
Value	Description									
0	No interrupt									
1	A floating-point divide by 0 exception has occurred.									
0	FPIDCRIS	RO	0	<p>Floating-Point Input Denormal Exception Raw Interrupt Status</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No interrupt</td></tr> <tr> <td>1</td><td>A floating-point input denormal exception has occurred.</td></tr> </tbody> </table> <p>This bit is cleared by writing a 1 to the IDCIC bit in the SYSEXCIC register.</p>	Value	Description	0	No interrupt	1	A floating-point input denormal exception has occurred.
Value	Description									
0	No interrupt									
1	A floating-point input denormal exception has occurred.									

Register 2: System Exception Interrupt Mask (SYSEXCIM), offset 0x004

The **SYSEXCIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

System Exception Interrupt Mask (SYSEXCIM)

Base 0x400F.9000
Offset 0x004
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RW	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	FPIXCIM	RW	0	Floating-Point Inexact Exception Interrupt Mask
	Value	Description		
	0	The FPIXCRIS interrupt is suppressed and not sent to the interrupt controller.		
	1	An interrupt is sent to the interrupt controller when the FPISCRIS bit in the SYSEXCRIS register is set.		
4	FPOFCIM	RW	0	Floating-Point Overflow Exception Interrupt Mask
	Value	Description		
	0	The FPOFCRIS interrupt is suppressed and not sent to the interrupt controller.		
	1	An interrupt is sent to the interrupt controller when the FPOFCRIS bit in the SYSEXCRIS register is set.		
3	FPUFCIM	RW	0	Floating-Point Underflow Exception Interrupt Mask
	Value	Description		
	0	The FPUFCRIS interrupt is suppressed and not sent to the interrupt controller.		
	1	An interrupt is sent to the interrupt controller when the FPUFCRIS bit in the SYSEXCRIS register is set.		

Bit/Field	Name	Type	Reset	Description
2	FPIOCIM	RW	0	Floating-Point Invalid Operation Interrupt Mask Value Description 0 The FPIOCRIS interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the FPIOCRIS bit in the SYSEXCRIS register is set.
1	FPDZCIM	RW	0	Floating-Point Divide By 0 Exception Interrupt Mask Value Description 0 The FPDZCRIS interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the FPDZCRIS bit in the SYSEXCRIS register is set.
0	FPIDCIM	RW	0	Floating-Point Input Denormal Exception Interrupt Mask Value Description 0 The FPIDCRIS interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the FPIDCRIS bit in the SYSEXCRIS register is set.

Register 3: System Exception Masked Interrupt Status (SYSEXCMIS), offset 0x008

The **SYSEXCMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

System Exception Masked Interrupt Status (SYSEXCMIS)

Base 0x400F.9000
Offset 0x008
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	FPIXCMIS	RO	0	Floating-Point Inexact Exception Masked Interrupt Status
	Value Description			
	0	An interrupt has not occurred or is masked.		
	1	An unmasked interrupt was signaled due to an inexact exception.		
	This bit is cleared by writing a 1 to the FPIXCIC bit in the SYSEXCIC register.			
4	FPOFCMIS	RO	0	Floating-Point Overflow Exception Masked Interrupt Status
	Value Description			
	0	An interrupt has not occurred or is masked.		
	1	An unmasked interrupt was signaled due to an overflow exception.		
	This bit is cleared by writing a 1 to the FPOFCIC bit in the SYSEXCIC register.			
3	FPUFCMIS	RO	0	Floating-Point Underflow Exception Masked Interrupt Status
	Value Description			
	0	An interrupt has not occurred or is masked.		
	1	An unmasked interrupt was signaled due to an underflow exception.		
	This bit is cleared by writing a 1 to the FPUFCIC bit in the SYSEXCIC register.			

Bit/Field	Name	Type	Reset	Description
2	FPIOCMIS	RO	0	<p>Floating-Point Invalid Operation Masked Interrupt Status</p> <p>Value Description</p> <p>0 An interrupt has not occurred or is masked.</p> <p>1 An unmasked interrupt was signaled due to an invalid operation.</p> <p>This bit is cleared by writing a 1 to the FPIOCIC bit in the SYSEXCIC register.</p>
1	FPDZCMIS	RO	0	<p>Floating-Point Divide By 0 Exception Masked Interrupt Status</p> <p>Value Description</p> <p>0 An interrupt has not occurred or is masked.</p> <p>1 An unmasked interrupt was signaled due to a divide by 0 exception.</p> <p>This bit is cleared by writing a 1 to the FPDZCIC bit in the SYSEXCIC register.</p>
0	FPIDCMIS	RO	0	<p>Floating-Point Input Denormal Exception Masked Interrupt Status</p> <p>Value Description</p> <p>0 An interrupt has not occurred or is masked.</p> <p>1 An unmasked interrupt was signaled due to an input denormal exception.</p> <p>This bit is cleared by writing a 1 to the FPIDCIC bit in the SYSEXCIC register.</p>

Register 4: System Exception Interrupt Clear (SYSEXCIC), offset 0x00C

The **SYSEXCIC** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

System Exception Interrupt Clear (SYSEXCIC)

Base 0x400F.9000
Offset 0x00C
Type W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	W1C	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	FPIXCIC	W1C	0	Floating-Point Inexact Exception Interrupt Clear Writing a 1 to this bit clears the FPIXCRIS bit in the SYSEXCRIS register and the FPIXCMIS bit in the SYSEXCMS register.
4	FPOFCIC	W1C	0	Floating-Point Overflow Exception Interrupt Clear Writing a 1 to this bit clears the FPOFCRIS bit in the SYSEXCRIS register and the FPOFCMIS bit in the SYSEXCMS register.
3	FPUFCIC	W1C	0	Floating-Point Underflow Exception Interrupt Clear Writing a 1 to this bit clears the FPUFCRIS bit in the SYSEXCRIS register and the FPUFCMIS bit in the SYSEXCMS register.
2	FPIOCIC	W1C	0	Floating-Point Invalid Operation Interrupt Clear Writing a 1 to this bit clears the FPIOCRIS bit in the SYSEXCRIS register and the FPIOCMIS bit in the SYSEXCMS register.
1	FPDZCIC	W1C	0	Floating-Point Divide By 0 Exception Interrupt Clear Writing a 1 to this bit clears the FPDZCRIS bit in the SYSEXCRIS register and the FPDZCMIS bit in the SYSEXCMS register.
0	FPIDCIC	W1C	0	Floating-Point Input Denormal Exception Interrupt Clear Writing a 1 to this bit clears the FPIDCRIS bit in the SYSEXCRIS register and the FPIDCMIS bit in the SYSEXCMS register.

7 Hibernation Module

The Hibernation Module manages removal and restoration of power to provide a means for reducing system power consumption. When the processor and peripherals are idle, power can be completely removed with only the Hibernation module remaining powered. Power can be restored based on an external signal or at a certain time using the built-in Real-Time Clock (RTC). The Hibernation module can be independently supplied from an external battery or an auxiliary power supply.

The Hibernation also integrates a tamper module which provides mechanisms to detect, respond to, and log system tampering events. The Tamper module is designed to be low power and operate from either a battery or the MCU I/O voltage supply.

The Hibernation module has the following features:

- 32-bit real-time seconds counter (RTC) with 1/32,768 second resolution and a 15-bit sub-seconds counter
 - 32-bit RTC seconds match register and a 15-bit sub seconds match for timed wake-up and interrupt generation with 1/32,768 second resolution
 - RTC predivider trim for making fine adjustments to the clock rate
- Hardware Calendar Function
 - Year, Month, Day, Day of Week, Hours, Minutes, Seconds
 - Four-year leap compensation
 - 24-hour or AM/PM configuration
- Two mechanisms for power control
 - System power control using discrete external regulator
 - On-chip power control using internal switches under register control
- V_{DD} supplies power when valid, even if $V_{BAT} > V_{DD}$
- Dedicated pin for waking using an external signal
- Capability to configure external reset (\overline{RST}) pin and/or up to four GPIO port pins as wake source, with programmable wake level
- Tamper Functionality
 - Support for four tamper inputs
 - Configurable level, weak pull-up, and glitch filter
 - Configurable tamper event response
 - Logging of up to four tamper events
 - Optional BBRAM erase on tamper detection
 - Tamper wake from hibernate capability

- Hibernation clock input failure detect with a switch to the internal oscillator on detection
- RTC operational and hibernation memory valid as long as V_{DD} or V_{BAT} is valid
- Low-battery detection, signaling, and interrupt generation, with optional wake on low battery
- GPIO pin state can be retained during hibernation
- Clock source from an internal low frequency oscillator (HIB LFIOSC) or a 32.768-kHz external crystal or oscillator
- Sixteen 32-bit words of battery-backed memory to save state during hibernation
- Programmable interrupts for:
 - RTC match
 - External wake
 - Low battery

7.1 Block Diagram

Figure 7-1. Hibernation Module Block Diagram

Note: References to alternate clock to LPC only apply to devices which have LPC.

7.2 Signal Description

The following table lists the external signals of the Hibernation module and describes the function of each.

The RTCCLK and TMPR [3 : 0] signals are alternate functions for a GPIO signal and defaults to be a GPIO signal at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the RTCCLK and TMPR [3 : 0] signals. The number in parentheses is the encoding that must be programmed into the PMCn field in the **GPIO Port Control (GPIOPTL)** register (page 816) to assign each signal to its specified GPIO port pin. In addition, the AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the proper HIB function. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769.

The remaining signals have a fixed pin assignment and function.

Note: In addition to the Hibernation signals that are part of the Hibernation Module, GPIO pins K[7:4] can be configured as external wake sources. Refer to “Waking from Hibernate” on page 576 for more information.

Note: Port pins PM[7:4] operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 769 and “Recommended GPIO Operating Characteristics” on page 2101 for more information.

Table 7-1. Hibernate Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
GNDX	R18	fixed	-	Power	GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.
HIB	M17	fixed	O	TTL	An output that indicates the processor is in Hibernate mode.
RTCCLK	M1 W16 C12	PC5 (7) PK7 (5) PP3 (7)	O	TTL	Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset.
TMPr0	N18	PM7	I/O	TTL	Tamper signal 0.
TMPr1	N19	PM6	I/O	TTL	Tamper signal 1.
TMPr2	G15	PM5	I/O	TTL	Tamper signal 2.
TMPr3	M18	PM4	I/O	TTL	Tamper signal 3.
VBAT	P19	fixed	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
WAKE	U18	fixed	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
XOSC0	T18	fixed	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
XOSC1	T19	fixed	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.

7.3 Functional Description

The Hibernation module provides two mechanisms for power control:

- The first mechanism uses internal switches to control power to the Cortex-M4F as well as to most analog and digital functions while retaining I/O pin power (VDD3ON mode).
- The second mechanism controls the power to the microcontroller with a control signal (**HIB**) that signals an external voltage regulator to turn on or off.

The Hibernation module power source is supplied by V_{DD} as long as it is within a valid range, even if $V_{BAT} > V_{DD}$. The Hibernation module also has an independent clock source to maintain a real-time

clock (RTC) when the system clock is powered down. Hibernate mode can be entered through one of two ways:

- The user initiates hibernation by setting the `HIBREQ` bit in the **Hibernation Control (HIBCTL)** register
- Power is arbitrarily removed from V_{DD} while a valid V_{BAT} is applied

Once in hibernation, the module signals an external voltage regulator to turn the power back on when an external pin (`WAKE`, `RST` or a wake-enabled GPIO pin) is asserted or when the internal RTC reaches a certain value. The Hibernation module can also detect when the battery voltage is low and optionally prevent hibernation or wake from hibernation when the battery voltage falls below a certain threshold. Note that multiple wake sources can be configured at the same time to generate a wake signal such that any of them can wake the module.

When waking from hibernation, the `HIB` signal is deasserted. The return of V_{DD} causes a POR to be executed. The time from when the `WAKE` signal is asserted to when code begins execution is equal to the wake-up time ($t_{WAKE_TO_HIB}$) plus the power-on reset time (T_{POR}).

7.3.1 Register Access Timing

Because the Hibernation module has an independent clocking domain, hibernation registers must be written only with a timing gap between accesses. The delay time is $t_{HIB_REG_ACCESS}$, therefore software must guarantee that this delay is inserted between back-to-back writes to Hibernation registers or between a write followed by a read. The `WC` interrupt in the **HIBMIS** register can be used to notify the application when the Hibernation modules registers can be accessed. Alternatively, software may make use of the `WRC` bit in the **Hibernation Control (HIBCTL)** register to ensure that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **HIBCTL** for `WRC=1` prior to accessing any hibernation register.

Back-to-back reads from Hibernation module registers have no timing restrictions. Reads are performed at the full peripheral clock rate.

7.3.2 Hibernation Clock Source

The HIB module can be clocked by one of three different clock sources:

- A 32.768-kHz oscillator
- An external 32.768-kHz clock source
- An internal low frequency oscillator (HIB LFIOSC)

Table 7-2 on page 566 summarizes the encodings for the bits in the **HIBCTL** register that are required for each clock source to be enabled. Note that `CLK32EN` must be set for any Hibernation clock source to be valid. The Hibernation module is not enabled until the `CLK32EN` bit is set. The HIB clock source is the source of the RTC Oscillator (RTCOOSC), which can be selected as the system clock source by programming a 0x4 in the `OSCSRC` field of the **Run and Sleep Mode Configuration (RSCLKCFG)** register in the System Control Module. Please refer to “System Control” on page 230 for more information.

Table 7-2. HIB Clock Source Configurations

HIB Clock Source	CLK32EN	OSCSEL	OSCBYP
32.768 kHz Oscillator	1	0	0
External 32.768-kHz Clock Source	1	0	1
Low-frequency internal oscillator (HIB LFIOSC) ^a	1	1	0

a. The frequency can have wide variations; refer to “Hibernation Clock Source Specifications” on page 2115 for more details.

To use an external crystal, a 32.768-kHz crystal is connected to the `XOSC0` and `XOSC1` pins. Alternatively, a 32.768-kHz oscillator can be connected to the `XOSC0` pin, leaving `XOSC1` unconnected. Care must be taken that the voltage amplitude of the 32.768-kHz oscillator is less than V_{BAT} , otherwise, the Hibernation module may draw power from the oscillator and not V_{BAT} during hibernation. See Figure 7-2 on page 567 and Figure 7-3 on page 567.

Alternatively, a low frequency oscillator source (HIB LFIOSC) present in the Hibernation module can be a clock source. (The frequency can have wide variations; refer to “Hibernation Clock Source Specifications” on page 2115 for more details.) The intent of this source is to provide an internal low power clock source to enable the use of the asynchronous pin wakes and memory storage without the requirement of an external crystal. To enable the HIB LFIOSC to be the clock source for the Hibernation module, both the `OSCSEL` bit and the `CLK32EN` bit in the **Hibernation Control (HIBCTL)** register must be set.

Note: The HIB low-frequency oscillator (HIB LFIOSC) has a wide frequency variation, therefore the RTC is not accurate when using this clock source. It is not recommended to use the HIB LFIOSC as an RTC clock source.

The Hibernation module is enabled by setting the `CLK32EN` bit of the **HIBCTL** register. The `CLK32EN` bit must be set before accessing any other Hibernation module register. The type of clock source used for the HIB module is selected by setting the `OSCSEL` and `OSCBYP` bit of the **HIBCTL** register. If the internal low frequency precision oscillator is used as the clock source, the `OSCSEL` bit should be set to a 1 at the same time the `CLK32EN` bit is set. If a crystal is used for the clock source, the software must leave a delay of t_{HIBOSC_START} after writing to the `CLK32EN` bit and before any other accesses to the Hibernation module registers. The delay allows the crystal to power up and stabilize. If an external oscillator is used for the clock source, no delay is needed. When using an external clock source, the `OSCBYP` bit in the **HIBCTL** register should be set. When using a crystal clock source, the `GNDX` pin should be connected to digital ground along with the crystal load capacitors, as shown in Figure 7-2 on page 567. When using an external clock source, the `GNDX` pin should be connected to digital ground.

Note: In the figures below the parameters R_{BAT} and C_{BAT} have recommended values of $51\Omega \pm 5\%$ and $0.1\mu F \pm 5\%$, respectively. See “Hibernation Module” on page 2121 for more information.

Figure 7-2. Using a Crystal as the Hibernation Clock Source with a Single Battery Source

Note: Some devices may not supply the GNDX signal. See "Signal Tables" on page 2032 for pins specific to your device.

X₁ = Crystal frequency is f_{XOSC_XTAL}.

C_{1,2} = Capacitor value derived from crystal vendor load capacitance specifications.

R_{PU} = Pull-up resistor is 200 kΩ

R_{BAT} = 51Ω ±5%

C_{BAT} = 0.1μF ±20%

See "Hibernation Clock Source Specifications" on page 2115 for specific parameter values.

Figure 7-3. Using a Dedicated Oscillator as the Hibernation Clock Source with VDD3ON Mode

Note: Some devices may not supply a GNDX signal. See "Signal Tables" on page 2032 for pins specific to your device.

R_{PU} = Pull-up resistor is 1 MΩ

R_{BAT} = 51Ω ±5%

C_{BAT} = 0.1μF ±20%

7.3.2.1 Hibernate Clock Output RTCOSC

The clock source that is configured as the HIB clock has the option of becoming an internal output, RTCOSC, and being selected as the clock source for the system clock. To enable RTCOSC as a system clock source, the **SYSCLKEN** bit must be set in the **Hibernate Clock Control (HIBCC)** register.

7.3.3 System Implementation

Several different system configurations are possible when using the Hibernation module:

- Using a single battery source, where the battery provides both V_{DD} and V_{BAT} , as shown in Figure 7-2 on page 567.
- Using the VDD3ON mode, where V_{DD} continues to be powered in hibernation, allowing the GPIO pins to retain their states, as shown in Figure 7-3 on page 567. In this mode, V_{DDC} is powered off internally. In VDD3ON mode, the RETCLR bit in the **HIBCTL** register must be set so that after power is reapplied, GPIO retention is held until software clears the bit. GPIO retention is released when software writes a 0 to the RETCLR bit.
- Using separate sources for V_{DD} and V_{BAT} . In this mode, additional circuitry is required for system start-up without a battery or with a depleted battery.
- Using a regulator to provide both V_{DD} and V_{BAT} with a switch enabled by \overline{HIB} to remove V_{DD} during hibernation as shown in Figure 7-4 on page 568.

Figure 7-4. Using a Regulator for Both V_{DD} and V_{BAT}

Note: Some devices may not supply a $GNDX$ signal. See “Signal Tables” on page 2032 for pins specific to your device.

Adding external capacitance to the V_{BAT} supply reduces the accuracy of the low-battery measurement and should be avoided if possible. The diagrams referenced in this section only show the connection to the Hibernation pins and not to the full system.

If the application does not require the use of the Hibernation module, refer to “Connections for Unused Signals” on page 2097. In this situation, the **HIB** bit in the **Hibernation Run Mode Clock Gating Control (RCGCHIB)** register must be cleared, disabling the system clock to the Hibernation module and Hibernation module registers are not accessible.

7.3.4 Battery Management

Important: System-level factors may affect the accuracy of the low-battery detect circuit. The designer should consider battery type, discharge characteristics, and a test load during battery voltage measurements.

The Hibernation module can be independently powered by a battery or an auxiliary power source using the VBAT pin. The module can monitor the voltage level of the battery and detect when the voltage drops below V_{LOWBAT} . The voltage threshold can be between 1.9 V and 2.5 V and is configured using the VBATSEL field in the **HIBCTL** register. The module can also be configured so that it does not go into Hibernate mode if the battery voltage drops below this threshold. In addition, battery voltage is monitored while in hibernation, and the microcontroller can be configured to wake from hibernation if the battery voltage goes below the threshold using the BATWKEN bit in the **HIBCTL** register.

The Hibernation module is designed to detect a low-battery condition and set the **LOWBAT** bit of the **Hibernation Raw Interrupt Status (HIBRIS)** register when this occurs. If the **VABORT** bit in the **HIBCTL** register is also set, then the module is prevented from entering Hibernate mode when a low-battery is detected. The module can also be configured to generate an interrupt for the low-battery condition (see “Interrupts and Status” on page 578).

7.3.5 Real-Time Clock

The RTC module is designed to keep wall time. The RTC can operate in seconds counter mode or calendar mode. A 32.768 kHz clock source along with a 15-bit predivider reduces the clock to 1 Hz. The 1 Hz clock is used to increment the 32-bit counter and keep track of seconds. In calendar mode, registers are provided which support the tracking of date, month, year and day-of-week. A match register can be configured to interrupt or wake the system from hibernate. In addition, a software trim register is implemented to allow the user to compensate for oscillator inaccuracies using software.

7.3.5.1 RTC Counter - Seconds/Subseconds Mode

The clock signal to the RTC is provided by either of the 32.768-kHz clock sources available to the Hibernation module. The **Hibernation RTC Counter (HIBRTCC)** register displays the seconds value. The **Hibernation RTC Sub Seconds register (HIBRTCSS)** is provided for additional time resolution of an application requiring less than one-second divisions.

The RTC is enabled by setting the **RTCEN** bit of the **HIBCTL** register. The **RTCEN** bit is also used along with the **CALEN** bit in the **Hibernation Calendar Control (HIBCALCTL)** register to enable the calendar. Thus, if the calendar is enabled, the RTC registers, **HIBRTCC**, **HIBRTCSS**, **HIBRTCM0** and **HIBRTCLD**, cannot be used. The RTC counter and sub-seconds counters begin counting immediately once **RTCEN** is set. Both counters count up. The RTC continues counting as long as the RTC is enabled and a valid V_{BAT} is present, regardless of whether V_{DD} is present or if the device is in hibernation.

The **HIBRTCC** register is set by writing the **Hibernation RTC Load (HIBRTCLD)** register. A write to the **HIBRTCLD** register clears the 15-bit sub-seconds counter field, **RTCSSC**, in the **HIBRTCSS** register. To ensure a valid read of the RTC value, the **HIBRTCC** register should be read first, followed by a read of the **RTCSSC** field in the **HIBRTCSS** register and then a re-read of the **HIBRTCC** register. If the two values for the **HIBRTCC** are equal, the read is valid. By following this procedure, errors in the application caused by the **HIBRTCC** register rolling over by a count of 1 during a read of the **RTCSSC** field are prevented. The RTC can be configured to generate an alarm by setting the **RTCAL0** bit in the **HIBIM** register. When an RTC match occurs, an interrupt is generated and displayed in the **HIBRIS** register. Refer to “RTC Match - Seconds/Subseconds Mode” on page 570 for more information.

If the RTC is enabled, only a cold POR, where both V_{BAT} and V_{DD} are removed, resets the RTC registers. If any other reset occurs while the RTC is enabled, such as an external \overline{RST} assertion or BOR reset, the RTC is not reset. The RTC registers can be reset under any type of system reset as long as the RTC, external wake pins and tamper pins are not enabled.

A buffered version of the 32.768-kHz signal Hibernate clock source is available on the RTCCLK signal output, which is muxed with a GPIO pin. The RTCCLK signal can be the external 32.786-kHz clock source or the HIB LFIOSC depending on the value of the OSCSEL bit in the **HIBCTL** register. See “Signal Description” on page 563 or pin mux information and “General-Purpose Input/Outputs (GPIOs)” on page 769 for additional details on initialization and configuration of this signal. The pin does not output RTCCLK when Hibernate mode is active or before the RTCCLK GPIO digital function has been selected through the **GPIO Digital Enable (GPIODEN)** register in the GPIO module. This includes selecting the RTCCLK signal as an output source in the **GPIO Port Control (GPIOPCTL)** register and setting the SYSCLKEN bit within the **Hibernate Clock Control (HIBCC)** register.

Note: The HIB low-frequency oscillator (HIB LFIOSC) has a wide frequency variation, therefore the RTC is not accurate when using this clock source. In addition, the RTCCLK signal may not meet the specification shown in Table 32-30 on page 2121.

7.3.5.2 RTC Match - Seconds/Subseconds Mode

The Hibernation module includes a 32-bit match register, **HIBRTCM0**, which is compared to the value of the RTC 32-bit counter, **HIBRTCC**. The match functionality also extends to the sub-seconds counter. The 15-bit field (RTCSSM) in the **HIBRTCSS** register is compared to the value of the 15-bit sub-seconds counter. When a match occurs, the RTCALTO bit is set in the **HIBRIS** register. For applications using Hibernate mode, the processor can be programmed to wake from Hibernate mode by setting the RTCWEN bit in the **HIBCTL** register. The processor can also be programmed to generate an interrupt to the interrupt controller by setting the RTCALTO bit in the **HIBIM** register.

The match interrupt generation takes priority over an interrupt clear. Therefore, writes to the RTCALTO bit in the **Hibernation Interrupt Clear (HIBIC)** register do not clear the RTCALTO bit if the **HIBRTCC** value and the **HIBRTCM0** value are equal. There are several methodologies to avoid this occurrence, such as writing a new value to the **HIBRTCLD** register prior to writing the **HIBIC** to clear the RTCALTO. Another example, would be to disable the RTC and re-enable the RTC by clearing and setting the RTCEN bit in the **HIBCTL** register.

Note: A Hibernate request made while a match event is valid causes the module to immediately wake up. This occurs when the RTCWEN bit is set and the RTCALTO bit in the **HIBRIS** register is set at the same time the HIBREQ bit in the **HIBCTL** register is written to a 1. This can be avoided by clearing the RTCALO bit in the **HIBRIS** register by writing a 1 to the corresponding bit in the **HIBIC** register before setting the HIBREQ bit. Another example would be to disable the RTC and re-enable the RTC by clearing and setting the RTCEN bit in the **HIBCTL** register.

7.3.5.3 RTC Calendar

The RTC Calendar function is selected by setting the CALEN bit in the **HIB Calendar Control (HIBCALCTL)** register. In this mode, six 32-bit registers provide the read (**HIBCAL0/1**), match (**HIBCALM0/1**), and load (**HIBCALLD0/1**) interface. The standard RTC registers: **HIBRTCC**, **HIBRTCLD**, **HIBRTCSS**, and **HIBRTCM0** are disabled when the calendar function is enabled and read back as all 0s in this mode. In addition, writes have no effect on these registers when the calendar function is enabled.

The **Hibernation Calendar n (HIBCALn)**, **Hibernation Calendar Match (HIBCALMn)** and **Hibernation Calendar Load (HIBCALLDn)** register fields are written or stored in hexadecimal.

When reading the **Hibernation Calendar n (HIBCALn)** registers, the status of the **VALID** bit in the **HIBCAL0/1** register must be checked to ensure the registers are in sync before reading.

The calendar function will keep track of the following:

- Seconds (0-59 seconds)
- Minutes (0-59 minutes)
- Hours (0-23 or 0-11 hours with an AM/PM option)
- Day of the week (0-6)
- Day of the month (1-31 days)
- Month (1-12 months)
- Year (00-99 years)

The hours may be reported with AM/PM or 24-hour based on the **CAL24** bit in the **HIBCALCTL** register. The leap year compensation is handled within the calendar function. The number of days in February are adjusted to 29 whenever the year is divisible by four.

RTC Calendar Match

The HIB Calendar Match function can be used to generate an interrupt on a match of seconds, minutes, hours, and day of month. The day of the week, year and month are not included in the match function. To ignore a match function for the hours, minutes, or seconds, set each of the upper two bits to 1 in the respective fields of the **HIBCALMn** register. To ignore the day of the month, set the **DOM** field to all zeros in the **HIBCALM1** register. If a match occurs in any field, the **RTCALTO** bit is set in the **HIBRIS** register.

7.3.5.4 RTC Trim

The RTC counting rate can be adjusted to compensate for inaccuracies in the clock source by using the predivider trim register, **HIBRTCT**. This register has a nominal value of 0x7FFF, and is used for one second out of every 64 seconds in RTC counter mode, when bits [5:0] in the **HIBRTCC** register change from 0x00 to 0x01, to divide the input clock. Trim is applied every 60 seconds in calendar mode. This configuration allows the software to make fine corrections to the clock rate by adjusting the predivider trim register up or down from 0x7FFF. The predivider trim should be adjusted up from 0x7FFF in order to slow down the RTC rate and down from 0x7FFF in order to speed up the RTC rate.

Care must be taken when using trim values that are near to the sub seconds match value in the **HIBRTCSS** register. It is possible when using trim values above 0x7FFF to receive two match interrupts for the same counter value. In addition, it is possible when using trim values below 0x7FFF to miss a match interrupt.

In the case of a trim value above 0x7FFF, when the **RTCSSC** value in the **HIBRTCSS** register reaches 0x7FFF, the **RTCC** value increments from 0x0 to 0x1 while the **RTCSSC** value is decreased by the trim amount. The **RTCSSC** value is counted up again to 0x7FFF before rolling over to 0x0 to begin counting up again. If the match value is within this range, the match interrupt is triggered twice. For example, as shown in Figure 7-5 on page 572, if the match interrupt was configured with **RTCM0**=0x1 and **RTCSSM**=0x7FFD, two interrupts would be triggered.

Figure 7-5. Counter Behavior with a TRIM Value of 0x8002

In the case of a trim value below 0x7FFF, the RTCSSC value is advanced from 0x7FFF to the trim value while the RTCC value is incremented from 0x0 to 0x1. If the match value is within that range, the match interrupt is not triggered. For example, as shown in Figure 7-6 on page 572, if the match interrupt was configured with RTCM0=0x1 and RTCSSM=0x2, an interrupt would never be triggered.

Figure 7-6. Counter Behavior with a TRIM Value of 0x7FFC

7.3.6 Tamper

The Tamper module provides a user with mechanisms to detect, respond to, and log system tampering events. The Tamper module is designed to be low power and operate either from a battery or the MCU I/O voltage supply. This module is a sub-module of the Hibernate module.

7.3.6.1 Tamper Block Diagram

Figure 7-7 on page 572 shows the Tamper block diagram.

Figure 7-7. Tamper Block Diagram

7.3.6.2 Functional Description

The Tamper module provides mechanisms to detect, respond, and log system tamper events. A tamper event is detected by state transitions on up to four GPIOs. The module may respond to a tamper event by clearing all or part of the hibernate module memory, generating a tamper event signal to the System Control module. The event will also be logged with a RTC time stamp to allow for tamper investigation.

Tamper Detection

Qualified tamper events are detected through an $XOSCn$ pin failure or through tamper I/O level matches which pass through a glitch filter. Tamper I/O pad events are detected by comparing the level on a tamper I/O pad with an expected value. The tamper I/O is sampled using the hibernate clock source and when the glitch filtering is enabled, must be stable for about 100 ms. This provides debounce filtering of a breakaway switch as a result of a drop impact. The tamper module contains one long glitch filter and one short glitch filter which uses an OR of the inputs as shown in Figure 7-8 on page 573. This implies if two Tamper inputs are asserted and one deasserts, the glitch filter runs to timeout or until the second Tamper input is deasserted. The glitch filter or tamper logging logic does not re-trigger if the tamper event match continues. The glitch filter resets on the deassertion of the tamper conditions or when a qualified tamper event is logged.

If the $XOSCn$ pins are enabled for use with the Hibernation module and subsequently fail, a tamper event is detected and is indicated by the STATE field in the **HIB Tamper Status (HIBTPSTAT)** register. In addition, the **XOSCST** and **XOSCFAIL** bits can be read for further details on the external oscillator source state.

Figure 7-8. Tamper Pad with Glitch Filtering

Tamper Event Responses

There are many responses to a tamper event including clearing some or all of Hibernate memory and generating a tamper signal to the System Control Module. The descriptions of the possible event responses follows.

- Tamper Register Status

The tamper status is indicated by the STATE bit field of the **HIB Tamper Status (HIBTPSTAT)** register. The register bits are reset to 0x0 on cold POR. When the tamper I/O is enabled/configured, the STATE field shows 0x1. The STATE field is set to 0x2 when a tamper event is detected. The software may reset the trigger source and the STATE field by writing to the TPCLR bit in the **HIBTPCTL** register.

- System Event Response

When a tamper event is detected, an NMI is generated. The NMI handler is responsible for performing any other system responses, including a simulate POR. If the tamper event was an XOSC fail condition, the part switches to the HIB LFIOSC. Once XOSC is stable, the XOSC may be enabled as the clock source once again.

- Hibernate Memory Clearing

On a tamper event, software has the option to clear all, the upper half, lower half, or none of the Hibernate memory. The feature is controlled through the MEMCLR field of the **HIBTPCTL** register.

- Wake from Hibernate

A tamper event will assert a wake event to the MCU if the WAKE bit in the **HIBTPCTL** register is set.

Tamper Event Logging

Up to four tamper events are stored in **HIB Tamper Log n (HIBTPLOGn)** registers within the Hibernate module. When a tamper event occurs the following status is logged:

- The RTC seconds or calendar values of year, minutes, day of month, hours and seconds in the **HIBTPLOG0/2/4/6** registers

Note: 24-hour mode must be used if RTC calendar mode is enabled. This mode is selected by setting the CAL24 bit in **HIB Calendar Control (HIBCALCTL)** register.

- The tamper status of the TMPR_n pins and the XOSC_n pins in the **HIBTPLOG1/3/5** registers. The **HIBTPLOG7** register captures the OR of all events occurring after the 3rd event is logged in the **HIBTPLOG5** register.

On the assertion of a qualified tamper event (rising edge) on any of the TMPR_n pins or an XOSC failure signal, the current status of all tamper inputs are logged in the **HIBTPLOGn** register.

Clearing a Tamper Event

After a tamper event, the **HIB Tamper Log (HIBTPLOGn)** registers and the NMI to the processor may be cleared by writing a 1 to the TPCLR bit in the **HIBTPCTL** register. This clear status is reflected by the STATE bit in the **HIBTPSTAT** register changing from 0x2 back to a 0x1. If the source of the tamper event comes from an XOSC failure, the clearing of a tamper event is delayed while the clock is switched to LFIOSC. The NMI interrupt handler may access the module immediately, but should read the **HIBTPLOGn** registers before issuing a tamper clear in the **HIBTPCTL** register.

Note: The **HIBTPLOG7** register is sticky and is cleared by a Hibernate module reset.

Tamper I/O Control

Up to four tamper I/Os are available. These signals are individually enabled and the detection level can be configured per pin. Enabling the tamper IO will override all settings made in the GPIO module. Each tamper IO has a weak pull-up.

Tamper Clocking

The Hibernate clock is the clock source for the Tamper module. When an external oscillator is used and tamper is enabled, the external oscillator is monitored by the Tamper module. If the external oscillator stops for any reason, the `XOSCFAIL` bit is set in the **HIBTPSTAT** register and the Hibernate clock source is switched to the HIB LFIOSC immediately. When the `XOSCST` bit in the **HIBTPSTAT** register is 0, indicating the external oscillator is active, a 1 can be written to the `XOSCFAIL` bit to clear it and re-enable the external 32.768-kHz oscillator.

Note: Because the HIB LFIOSC has a wide frequency variation, it should not be configured as the HIB clock source when accurate monitoring of the tamper logs are important.

Tamper Resets

The Tamper module uses the resets from the Hibernate module.

Important: The Hibernation module registers are reset under two conditions:

1. Any type of system reset (if the `RTCEN` and the `PINWEN` bits in the **HIBCTL** register are clear and the `TPEN` bit in the **HIBTPCTL** register is clear).
2. A cold POR occurs when both the V_{DD} and V_{BAT} supplies are removed.

Any other reset condition is ignored by the Hibernation module.

7.3.7 Battery-Backed Memory

The Hibernation module contains 16 32-bit words of memory that are powered from the battery or an auxiliary power supply and therefore retained during hibernation. The processor software can save state information in this memory prior to hibernation and recover the state upon waking. To access the upper eight words of memory, the processor must be in privilege mode. Refer to “Processor Mode and Privilege Levels for Software Execution” on page 93 for more information about processor privilege mode. The battery-backed memory can be accessed through the **HIBDATA** registers. If both V_{DD} and V_{BAT} are removed, the contents of the **HIBDATA** registers are not retained.

7.3.8 Power Control Using \overline{HIB}

Important: The Hibernation Module requires special system implementation considerations when using \overline{HIB} to control power, as it is intended to power-down all other sections of the microcontroller. All system signals and power supplies that connect to the chip must be driven to 0 V or powered down with the same regulator controlled by \overline{HIB} .

The Hibernation module controls power to the microcontroller through the use of the \overline{HIB} pin which is intended to be connected to the enable signal of the external regulator(s) providing 3.3 V to the microcontroller and other circuits. When the \overline{HIB} signal is asserted by the Hibernation module, the external regulator is turned off and no longer powers the microcontroller and any parts of the system that are powered by the regulator. The Hibernation module remains powered from the V_{BAT} supply until a Wake event. Power to the microcontroller is restored by deasserting the \overline{HIB} signal, which causes the external regulator to turn power back on to the chip.

7.3.9 Power Control Using VDD3ON Mode

The Hibernation module may also be configured to cut power to all internal modules during Hibernate mode. While in this state, if VDD3ON is set in the **HIBCTL** register, all pins are held in the state they were in prior to entering hibernation. For example, inputs remain inputs; outputs driven high remain driven high, and so on. There are important procedural and functional items to note when in VDD3ON mode:

- JTAG Ports C[0] - C[3] do not retain their state in Hibernate VDD3ON mode.
- If GPIO pins K[7:4] are not used as a wake source, they should not be left floating. An internal pull-up resistor may be configured by the application before entering Hibernate mode by programming the **GPIO Pull-Up Select (GPIOPUR)** register in the GPIO module.
- In the VDD3ON mode, the regulator should maintain 3.3 V power to the microcontroller during Hibernate. GPIO retention is disabled when the RETCLR bit is cleared in the **HIBCTL** register.
- When entering hibernation in VDD3ON mode, the supply rails to the Ethernet resistors R1, R2, R3, R4 found in Figure 24-16 on page 1653 must be switched off.

7.3.10 Initiating Hibernate

Hibernate mode is initiated when the **HIBREQ** bit of the **HIBCTL** register is set. If a wake-up condition has not been configured using the **PINWEN** or **RTCWEN** bits in the **HIBCTL** register, the hibernation request is ignored. In addition, if the battery voltage is below the threshold voltage defined by the **VBATSEL** field in the **HIBCTL** register, the hibernation request is ignored.

7.3.11 Waking from Hibernate

The Hibernation module can be configured to wake from Hibernate mode if any of the following are enabled:

- External **WAKE**
- External **RST**
- GPIO K[7:4]
- Tamper **TMPR [3 : 0]**
- Tamper **XOSC** failure

The Hibernation module can also be configured to wake from hibernate when the following events occur:

- RTC match wake event
- Low Battery wake event

The external **WAKE** pin is enabled by setting the **PINWEN** bit in the **HIBCTL** register. The external **WAKE** pin can generate an interrupt by programming the **EXTWEN** bit in the **Hibernation Interrupt Mask (HIBIM)** register.

Note: If an external **WAKE** signal is asserted, the application is responsible for clearing the signal source once the **EXTWEN** bit has been registered in the **Hibernation Raw Interrupt Status (HBRIS)** register.

To use the **RST** pin as a wake source, the **WURSTEN** bit must be set in the **Hibernate I/O Configuration (HIBIO)** register and the **WUUNLK** bit must be set in the same register.

To enable any of the assigned GPIO pins as a wake source, the **WUUNLK** bit must be set in the **HIBIO** register and the wake configuration must be programmed through the **GPIOWAKEPEN** and **GPIOWAKELVL** registers in the GPIO module. Please refer to “General-Purpose Input/Outputs (GPIOs)” on page 769 for more information on programming the GPIOs.

Note: The **RST** pin and GPIO wake sources are cleared by a write to either or both the **RSTWK** and **PADIOWK** bits. This clears the source of interrupts for **RSTWK**, **PADIOWK** and the **GPIOWAKESTAT** register.

TMPR[3:0] are enabled by setting the appropriate **ENn** bits the **Tamper IO Control and Status (HIBTPIO)** register. The **HIBTPIO** register overrides the GPIO port configuration registers. By setting the **WAKE** bit in the **Tamper Control (HIBTPCTL)** register, a tamper event can cause a wake from Hibernate. If a tamper event occurs, the time of the event and the status of the tamper pins are logged in the **Tamper Log (HIBTPLOG)** register.

By setting the **RTCWEN** bit in the **HIBCTL** register a wake from hibernate can occur when the value of the **HIBRTCC** register matches the value of the **HIBRTCM0** register and the value of the **RTCSSC** field matches the **RTCSSM** field in the **HIBTCSS** register.

To allow a wake from Hibernate on a low battery event, the **BATWKEN** bit in the **HIBCTL** register must be set. In this configuration, the battery voltage is checked every 512 seconds while in hibernation. If the voltage is below the level specified by the **VBATSEL** field, the **LOWBAT** interrupt is set in the **HIBRIS** register.

Upon external wake-up, external reset, tamper event, or RTC match, the Hibernation module delays coming out of hibernation until V_{DD} is above the minimum specified voltage, see Table 32-6 on page 2101.

When the Hibernation module wakes, the microcontroller performs a normal power-on reset. The normal power-on reset does not reset the Hibernation module or Tamper module, but does reset the rest of the microcontroller. Software can detect that the power-on was due to a wake from hibernation by examining the raw interrupt status register (see “Interrupts and Status” on page 578) and by looking for state data in the battery-backed memory (see “Battery-Backed Memory” on page 575).

7.3.12 Arbitrary Power Removal

The microcontroller goes into hibernation if V_{DD} is arbitrarily removed when the **CLK32EN** bit is set and any of the following bits are set:

- **TPEN** bit in the **HIBTPCTL** register
- **PINWEN** bit in the **HIBCTL** register
- **RTCEN** bit in the **HIBCTL** register

The microcontroller wakes from hibernation when power is reapplied.

If the **CLK32EN** bit is set but the **TPEN**, **PINWEN**, and **RTCEN** bits are all clear, the microcontroller still goes into hibernation if power is removed; however, when V_{DD} is reapplied, the MCU executes a cold POR and the Hibernation module is reset. If the **CLK32EN** bit is not set and V_{DD} is arbitrarily removed, the part is simply powered off and executes a cold POR when power is reapplied.

If V_{DD} is arbitrarily removed while a Flash memory or **HIBDATA** register write operation is in progress, the write operation must be retried after V_{DD} is reapplied.

7.3.13 Interrupts and Status

The Hibernation module can generate interrupts when the following conditions occur:

- Assertion of \overline{WAKE} pin
- RTC match
- Low battery detected
- Write complete/capable
- Assertion of an external \overline{RESET} pin
- Assertion of an external wake-enabled GPIO pin (port K[7:4])

All of the interrupts except for the tamper signals are ORed together before being sent to the interrupt controller, so the Hibernate module can only generate a single interrupt request to the controller at any given time. The software interrupt handler can service multiple interrupt events by reading the **Hibernation Masked Interrupt Status (HIBMIS)** register. Software can also read the status of the Hibernation module at any time by reading the **HIBRIS** register which shows all of the pending events. This register can be used after waking from hibernation to see if a wake condition was caused by one of the events above or by a power loss.

The events that can trigger an interrupt are configured by setting the appropriate bits in the **Hibernation Interrupt Mask (HIBIM)** register. Pending interrupts can be cleared by writing the corresponding bit in the **Hibernation Interrupt Clear (HIBIC)** register.

7.4 Initialization and Configuration

The Hibernation module has several different configurations. The following sections show the recommended programming sequence for various scenarios. Because the Hibernation module runs at a low frequency and is asynchronous to the rest of the microcontroller, which is run off the system clock, software must allow a delay of $t_{HIB_REG_ACCESS}$ after writes to registers (see “Register Access Timing” on page 565). The **wc** interrupt in the **HIBMIS** register can be used to notify the application when the Hibernation modules registers can be accessed.

7.4.1 Initialization

The Hibernation module comes out of reset with the system clock enabled to the module, but if the system clock to the module has been disabled, then it must be re-enabled, even if the RTC feature is not used. See page 403.

If a 32.768-kHz crystal is used as the Hibernation module clock source, perform the following steps:

1. Write 0x0000.0010 to the **HIBIM** register to enable the **wc** interrupt.
2. Write 0x40 to the **HIBCTL** register at offset 0x10 to enable the oscillator input.
3. Wait until the **wc** interrupt in the **HIBMIS** register has been triggered before performing any other operations with the Hibernation module.

If a 32.768-kHz single-ended oscillator is used as the Hibernation module clock source, then perform the following steps:

1. Write 0x0000.0010 to the **HIBIM** register to enable the WC interrupt.
2. Write 0x0001.0040 to the **HIBCTL** register at offset 0x10 to enable the oscillator input and bypass the on-chip oscillator.
3. Wait until the WC interrupt in the **HIBMIS** register has been triggered before performing any other operations with the Hibernation module.

If the internal low frequency oscillator is used as the Hibernation module clock source, then perform the following steps:

1. Write 0x0000.0010 to the **HIBIM** register to enable the WC interrupt.
2. Write 0x0008.0040 to the **HIBCTL** register at offset 0x10 to enable the internal low frequency oscillator.
3. Wait until the WC interrupt in the **HIBMIS** register has been triggered before performing any other operations with the Hibernation module.

The above steps are only necessary when the entire system is initialized for the first time. If the microcontroller has been in hibernation, then the Hibernation module has already been powered up and the above steps are not necessary. The software can detect that the Hibernation module and clock are already powered by examining the CLK32EN bit of the **HIBCTL** register.

7.4.2 RTC Match Functionality (No Hibernation)

Use the following steps to implement the RTC match functionality of the Hibernation module:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write the required RTC match value to the **HIBRTCM0** register at offset 0x004 and the RTCSSM field in the **HIBTCSS** register at offset 0x028.
3. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C.
4. Set the required RTC match interrupt mask in the RTCALT0 in the **HIBIM** register at offset 0x014.
5. Write 0x0000.0041 to the **HIBCTL** register at offset 0x010 to enable the RTC to begin counting.

7.4.3 RTC Match/Wake-Up from Hibernation

Use the following steps to implement the RTC match and wake-up functionality of the Hibernation module:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write the required RTC match value to the **HIBRTCM0** register at offset 0x004 and the RTCSSM field in the **HIBTCSS** register at offset 0x028.
3. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C. This write causes the 15-bit sub seconds counter to be cleared.

4. Write any data to be retained during hibernation to the **HIBDATA** register at offsets 0x030-0x06F.
5. Set the RTC Match Wake-Up and start the hibernation sequence by writing 0x0000.004B to the **HIBCTL** register at offset 0x010.

7.4.4 External Wake-Up from Hibernation

Use the following steps to implement the Hibernation module with the external **WAKE** pin as the wake-up source for the microcontroller:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write any data to be retained during hibernation to the **HIBDATA** register at offsets 0x030-0x06F.
3. Enable the external wake and start the hibernation sequence by writing 0x0000.0052 to the **HIBCTL** register at offset 0x010.

Use the following steps to program the external **RESET** pin as the wake source for the microcontroller:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write any data to be retained during hibernation to the **HIBDATA** register at offsets 0x030-0x06F.
3. Enable the external **RESET** pin as a wake source by writing a 0x0000.0011 to the **HIBIO** register at offset 0x02C.
4. When the **IOWRC** bit in the **HIBIO** register is read as 1, clear the **WUUNLK** bit in the **HIBIO** register to lock the current pad configuration so that any other writes to the **WURSTEN** bit in the **HIBIO** register will be ignored.
5. The hibernation sequence may be initiated by writing 0x4000.0152 to the **HIBCTL** register. Note that when using **RESET**, the user must enable VDD3ON mode and set the **RETCLR** bit in the **HIBCTL** register.

Use the following steps to program GPIO port K pins K[7:4] as the wake source for the microcontroller:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write any data to be retained during hibernation to the **HIBDATA** register at offsets 0x030-0x06F.
3. Configure the **GPIOWAKEPEN** and **GPIOWAKELVL** registers at offsets 0x540 and 0x544 in the GPIO module. Enable the I/O wake pad configuration by writing 0x0000.0001 to the **HIBIO** register at offset 0x010.
4. When the **IOWRC** bit in the **HIBIO** register is read as 1, write 0x0000.0000 to the **HIBIO** register to lock the current pad configuration so that any other writes to the **GPIOWAKEPEN** and **GPIOWAKELVL** register will be ignored.
5. Clear any pending interrupts by writing a 1 to the **PADIOWK** bit in the **HIBIC** register.

6. The hibernation sequence may be initiated by writing 0x4000.0152 to the **HIBCTL** register. Note for Port M external wake, the user must enable VDD3ON mode and set the RETCLR bit in the **HIBCTL** register.

7.4.5 RTC or External Wake-Up from Hibernation

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write the required RTC match value to the **HIBRTCM0** register at offset 0x004 and the RTCSSM field in the **HIBRTCSS** register at offset 0x028.
3. Write the required RTC load value to the **HIBRTCLD** register at offset 0x00C. This write causes the 15-bit sub seconds counter to be cleared.
4. Write any data to be retained during hibernation to the **HIBDATA** register at offsets 0x030-0x06F.
5. Set the RTC Match/External Wake-Up and start the hibernation sequence by writing 0x0000.005B to the **HIBCTL** register at offset 0x010.

7.4.6 Tamper Initialization

Use the following steps to configure the Tamper module to interrupt the processor when a **TMPR** signal has triggered:

Note: Unlike other functions, the Tamper pins do not need to be configured for the GPIO in the **GPIOAFSEL** register. The **Tamper IO Control and Status (HIBTPIO)** register overrides configurations made to the GPIO module.

1. Write 0x0000.0041 to the **HIBCTL** register at offset 0x010 to enable the 32.768-kHz Hibernate oscillator and enable the RTC.
2. Enable the four Tamper I/O to trigger on the a high state on any of the pins by writing 0x0F0F.0F0F to the **HIBTPIO** register at offset 0x410.
3. Write 0x0000.0001 to the **HIBTPCTL** register to enable the tamper.

Note: Once tamper is enabled, the following **HIBCTL** register bits are locked and cannot be modified:

- OSCSEL
- OSCDRV
- OSCBYP
- VDD3ON
- CLK32EN
- RTCEN

7.5 Register Map

Table 7-3 on page 582 lists the Hibernation registers. All addresses given are relative to the Hibernation Module base address at 0x400F.C000. Note that the system clock to the Hibernation module must be enabled before the registers can be programmed (see page 403). There must be a delay of 3 system clocks after the Hibernation module clock is enabled before any Hibernation module registers

are accessed. In addition, the CLK32EN bit in the **HIBCTL** register must be set before accessing any other Hibernation module register.

Note: Except for the **HIBIO** and a portion of the **HIBIC** register, all other Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the WRC bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the WRC bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 565. The **HIBIO** register and bits RSTWK, PADIOWK and WC of the **HIBIC** register do not require waiting for write to complete. Because these registers are clocked by the system clock, writes to these registers/bits are immediate.

Writing to registers other than the **HIBCTL** and **HIBIM** before the CLK32EN bit in the **HIBCTL** register has been set may produce unexpected results.

Important: The Hibernation module registers are reset under two conditions:

1. Any type of system reset (if the RTCEN and the PINWEN bits in the **HIBCTL** register are clear and the TPEN bit in the **HIBTPCTL** register is clear).
2. A cold POR occurs when both the V_{DD} and V_{BAT} supplies are removed.

Any other reset condition is ignored by the Hibernation module.

Note that the following registers are only accessed through privileged mode (see “System Control” on page 230 for more details):

- **HIBTPCTL**
- **HIBPTSTAT**
- **HIBTPIO**
- **HIBTPLOG**
- Upper eight words of memory (**HIBDATA** register 0x50 to 0x6F)

Table 7-3. Hibernation Module Register Map

7.6 Register Descriptions

The remainder of this section lists and describes the Hibernation module registers, in numerical order by address offset.

Register 1: Hibernation RTC Counter (HIBRTCC), offset 0x000

This register is the current 32-bit value of the RTC counter.

The RTC counter consists of a 32-bit seconds counter and a 15-bit sub seconds counter. The RTC counters are reset by the Hibernation module reset. The RTC 32-bit seconds counter can be set by the user using the **HIBRTCLD** register. When the 32-bit seconds counter is set, the 15-bit sub second counter is cleared.

The RTC value can be read by first reading the **HIBRTCC** register, reading the RTCSSC field in the **HIBRTCSS** register, and then rereading the **HIBRTCC** register. If the two values for **HIBRTCC** are equal, the read is valid.

Note: There is a minimum system clock rate of three times the HIB clock rate to properly read the **HIBRTCC** register.

Hibernation RTC Counter (HIBRTCC)

Base 0x400F.C000

Offset 0x000

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	RTCC	RO	0x0000.0000	RTC Counter

A read returns the 32-bit counter value, which represents the seconds elapsed since the RTC was enabled. This register is read-only. To change the value, use the **HIBRTCLD** register.

Register 2: Hibernation RTC Match 0 (HIBRTCM0), offset 0x004

This register is the 32-bit seconds match register for the RTC counter. The 15-bit sub second match value is stored in the reading the RTCSSC field in the **HIBRTCSS** register and can be used in conjunction with this register for a more precise time match.

Note: Except for the **HIBIO** and a portion of the **HIBIC** register, all other Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the WRC bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the WRC bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 565. The **HIBIO** register and bits RSTWK, PADIOWK and WC of the **HIBIC** register do not require waiting for write to complete. Because these registers are clocked by the system clock, writes to these registers/bits are immediate.

Writing to registers other than the **HIBCTL** and **HIBIM** before the CLK32EN bit in the **HIBCTL** register has been set may produce unexpected results.

Hibernation RTC Match 0 (HIBRTCM0)

Base 0x400F.C000

Offset 0x004

Type RW, reset 0xFFFF.FFFF

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RTCM0																
Type	RW															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
RTCM0																
Type	RW															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0

Bit/Field	Name	Type	Reset	Description
31:0	RTCM0	RW	0xFFFF.FFFF	RTC Match 0 A write loads the value into the RTC match register. A read returns the current match value.

Register 3: Hibernation RTC Load (HIBRTCLD), offset 0x00C

This register is used to load a 32-bit value loaded into the RTC counter. The load occurs immediately upon this register being written. When this register is written, the 15-bit sub seconds counter is also cleared.

Note: This register is protected from errant code by using the **HIBLOCK** register. This register is write-only; any reads to this register read back as zeros.

Note: Except for the **HIBIO** and a portion of the **HIBIC** register, all other Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 565. The **HIBIO** register and bits **RSTWK**, **PADIOWK** and **WC** of the **HIBIC** register do not require waiting for write to complete. Because these registers are clocked by the system clock, writes to these registers/bits are immediate.

Writing to registers other than the **HIBCTL** and **HIBIM** before the **CLK32EN** bit in the **HIBCTL** register has been set may produce unexpected results.

Hibernation RTC Load (HIBRTCLD)

Base 0x400F.C000

Offset 0x00C

Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	RTCLD	WO	0x0000.0000	RTC Load A write loads the current value into the RTC counter (RTCC). A read returns the 32-bit load value.

Register 4: Hibernation Control (HIBCTL), offset 0x010

This register is the control register for the Hibernation module. This register must be written last before a hibernate event is issued. Writes to other registers after the HIBREQ bit is set are not guaranteed to complete before hibernation is entered.

Note: Writes to this register have special timing requirements. Software should make use of the WRC bit in the **HIBCTL** register to ensure that the required synchronization has elapsed. While the WRC bit is clear, any attempts to write this register are ignored. Reads may occur at any time.

Note that once tamper is enabled, the following **HIBCTL** clock configuration bits and bus write stall bit are locked and cannot be modified:

- OSCSEL
- OSCDRV
- OSCBYP
- VDD3ON
- CLK32EN
- RTCEN

Bit/Field Name Type Reset Description

31 WRC RO 1 Write Complete/Capable

Value Description

- | | |
|---|--|
| 0 | The interface is processing a prior write and is busy. Any write operation that is attempted while WRC = 0 results in undetermined behavior. |
| 1 | The interface is ready to accept a write. |

Software must poll this bit between write requests and defer writes until WRC=1 to ensure proper operation. An interrupt can be configured to indicate the WRC has completed.

The bit name WRC means "Write Complete," which is the normal use of the bit (between write accesses). However, because the bit is set out-of-reset, the name can also mean "Write Capable" which simply indicates that the interface may be written to by software. This difference may be exploited by software at reset time to detect which method of programming is appropriate: 0 = software delay loops required; 1 = WRC paced available.

An interrupt may be generated in active mode.</td></tr> </tbody> </table>	Value	Description	0	The status of the \overline{WAKE} or an external I/O wake pad source pin has no effect on hibernation.	1	An assertion of the \overline{WAKE} pin or an external I/O wake pad source takes the microcontroller out of hibernation. An interrupt may be generated in active mode.
Value	Description									
0	The status of the \overline{WAKE} or an external I/O wake pad source pin has no effect on hibernation.									
1	An assertion of the \overline{WAKE} pin or an external I/O wake pad source takes the microcontroller out of hibernation. An interrupt may be generated in active mode.									

Bit/Field	Name	Type	Reset	Description
3	RTCWEN	RW	0	RTC Wake-up Enable Value Description 0 An RTC match event has no effect on hibernation. 1 An RTC match event (the value the HIBRTCC register matches the value of the HIBRTCM0 register and the value of the RTCSSC field matches the RTCSSM field in the HIBRTCSS register) takes the microcontroller out of hibernation.
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	HIBREQ	RW	0	Hibernation Request Value Description 0 No hibernation request. 1 Set this bit to initiate hibernation. After a wake-up event, this bit is automatically cleared by hardware. A hibernation request is ignored if both the PINWEN and RTCWEN bits are clear.
0	RTCEN	RW	0	RTC Timer/Calendar Enable This is bit must be set to enable RTC or calendar mode. For calendar mode enable, the CALEN bit in the HIBCALCTL register must also be set. Value Description 0 The Hibernation module RTC and calendar mode are disabled. 1 The Hibernation module RTC and calendar mode are enabled. Note: The low-frequency oscillator has a wide frequency variation, therefore the RTC is not accurate when using this clock source.

Register 5: Hibernation Interrupt Mask (HIBIM), offset 0x014

This register is the interrupt mask register for the Hibernation module interrupt sources. Each bit in this register masks the corresponding bit in the **Hibernation Raw Interrupt Status (HIBRIS)** register. If a bit is unmasked, the interrupt is sent to the interrupt controller. If the bit is masked, the interrupt is not sent to the interrupt controller. The WC bit of the **HIBIM** register may be set before the CLK32EN bit of the **HIBCTL** register is set. This allows software to use the WC interrupt trigger to detect when the RTCOSC clock is stable, which may be in excess of one second. If the WC bit is set before the CLK32EN has been set, the mask value is not preserved over a hibernate cycle unless the bit is written a second time.

Note: The WC bit of this register is in the system clock domain such that a write to this bit is immediate and may be done before the CLK32EN bit is set in the **HIBCTL** register.

1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	RTCALTO	RW	0	RTC Alert 0 Interrupt Mask Value Description 0 The RTCALTO interrupt is suppressed and not sent to the interrupt controller. 1 An interrupt is sent to the interrupt controller when the RTCALTO bit in the HIBRIS register is set.

Register 6: Hibernation Raw Interrupt Status (HIBRIS), offset 0x018

This register is the raw interrupt status for the Hibernation module interrupt sources. Each bit can be masked by clearing the corresponding bit in the **HIBIM** register. When a bit is masked, the interrupt is not sent to the interrupt controller. Bits in this register are cleared by writing a 1 to the corresponding bit in the **Hibernation Interrupt Clear (HIBIC)** register or by entering hibernation.

Register 7: Hibernation Masked Interrupt Status (HIBMIS), offset 0x01C

This register is the masked interrupt status for the Hibernation module interrupt sources. Bits in this register are the AND of the corresponding bits in the **HIBRIS** and **HIBIM** registers. When both corresponding bits are set, the bit in this register is set, and the interrupt is sent to the interrupt controller.

Hibernation Masked Interrupt Status (HIBMIS)

Base 0x400F.C000
Offset 0x01C
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	VDDFAIL	RO	0	VDD Fail Interrupt Mask
		Value	Description	
		0	An VDDFAIL interrupt has not occurred or is masked.	
		1	An unmasked interrupt was signaled due to a an arbitrary loss of power or because one or more of the voltage supplies (VDD, VDDA or VDDC) has dropped below the defined operating range.	
6	RSTWK	RO	0	Reset Pad I/O Wake-Up Interrupt Mask
		Value	Description	
		0	An external reset interrupt has not occurred or is masked.	
		1	An unmasked interrupt was signaled due to a <u>RESET</u> pin assertion.	
5	PADIOWK	RO	0	Pad I/O Wake-Up Interrupt Mask
		Value	Description	
		0	An external GPIO or reset interrupt has not occurred or is masked.	
		1	An unmasked interrupt was signaled due to a wake-enabled GPIO or <u>RESET</u> pin assertion.	

Bit/Field	Name	Type	Reset	Description
4	WC	RO	0	<p>Write Complete/Capable Masked Interrupt Status</p> <p>Value Description</p> <p>0 The WRC bit has not been set or the interrupt is masked.</p> <p>1 An unmasked interrupt was signaled due to the WRC bit being set.</p> <p>This bit is cleared by writing a 1 to the WC bit in the HIBIC register.</p>
3	EXTW	RO	0	<p>External Wake-Up Masked Interrupt Status</p> <p>Value Description</p> <p>0 An external wake-up interrupt has not occurred or is masked.</p> <p>1 An unmasked interrupt was signaled due to a WAKE pin assertion.</p> <p>This bit is cleared by writing a 1 to the EXTW bit in the HIBIC register.</p>
2	LOWBAT	RO	0	<p>Low Battery Voltage Masked Interrupt Status</p> <p>Value Description</p> <p>0 A low-battery voltage interrupt has not occurred or is masked.</p> <p>1 An unmasked interrupt was signaled due to a low-battery voltage condition.</p> <p>This bit is cleared by writing a 1 to the LOWBAT bit in the HIBIC register.</p>
1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	RTCALTO	RO	0	<p>RTC Alert 0 Masked Interrupt Status</p> <p>Note: The MIS may apply to either the RTC or calendar block depending on which is enabled.</p> <p>Value Description</p> <p>0 An RTC or calendar match interrupt has not occurred or is masked.</p> <p>1 An unmasked interrupt was signaled due to an RTC or calendar match.</p> <p>This bit is cleared by writing a 1 to the RTCALTO bit in the HIBIC register.</p>

Register 8: Hibernation Interrupt Clear (HIBIC), offset 0x020

This register is the interrupt write-one-to-clear register for the Hibernation module interrupt sources. Writing a 1 to a bit clears the corresponding interrupt in the **HIBRIS** register.

Note: Writes to the RSTWK, PADIOWK and WC bits of this register are immediate and the status may be read from the **HIBRIS** and **HIBMIS** registers without monitoring the WRC bit of the **HIBCTL** register.

Note: All I/O wake sources are cleared by a write to either or both the RSTWK and PADIOWK bits. This clears the source of interrupts for RSTWK, PADIOWK and the **GPIOWAKESTAT** register.

Hibernation Interrupt Clear (HIBIC)

Base 0x400F.C000
Offset 0x020
Type RW1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	VDDFAIL	RW1C	0	VDD Fail Interrupt Clear Writing a 1 to this bit clears the VDDFAIL bit in the HIBRIS and HIBMIS registers. Reads return the raw interrupt status.
6	RSTWK	RW1C	0	Reset Pad I/O Wake-Up Interrupt Clear Writing a 1 to this bit clears the RSTWK bit in the HIBRIS and HIBMIS registers. Reads return the raw interrupt status.
5	PADIOWK	RW1C	0	Pad I/O Wake-Up Interrupt Clear Writing a 1 to this bit clears the PADIOWK bit in the HIBRIS and HIBMIS registers. Reads return the raw interrupt status.
4	WC	RW1C	0	Write Complete/Capable Interrupt Clear Writing a 1 to this bit clears the WC bit in the HIBRIS and HIBMIS registers. Reads return the raw interrupt status.
3	EXTW	RW1C	0	External Wake-Up Interrupt Clear Writing a 1 to this bit clears the EXTW bit in the HIBRIS and HIBMIS registers. Reads return the raw interrupt status.

Bit/Field	Name	Type	Reset	Description
2	LOWBAT	RW1C	0	<p>Low Battery Voltage Interrupt Clear</p> <p>Writing a 1 to this bit clears the LOWBAT bit in the HIBRIS and HIBMIS registers.</p> <p>Reads return the raw interrupt status.</p>
1	reserved	RO	0	<p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>
0	RTCALT0	RW1C	0	<p>RTC Alert0 Masked Interrupt Clear</p> <p>Writing a 1 to this bit clears the RTCALT0 bit in the HIBRIS and HIBMIS registers.</p> <p>Reads return the raw interrupt status.</p> <p>Note: The timer interrupt source cannot be cleared if the RTC value and the HIBRTCM0 register / RTCMSS field values are equal. The match interrupt takes priority over the interrupt clear.</p>

Register 9: Hibernation RTC Trim (HIBRTCT), offset 0x024

This register contains the value that is used to trim the RTC clock predivider. It represents the computed underflow value that is used during the trim cycle. It is represented as $0x7FFF \pm N$ clock cycles, where N is the number of clock cycles to add or subtract every 64 seconds in RTC mode or 60 seconds in calendar mode.

Note: Except for the **HIBIO** and a portion of the **HIBIC** register, all other Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 565. The **HIBIO** register and bits **RSTWK**, **PADIOWK** and **WC** of the **HIBIC** register do not require waiting for write to complete. Because these registers are clocked by the system clock, writes to these registers/bits are immediate.

Writing to registers other than the **HIBCTL** and **HIBIM** before the **CLK32EN** bit in the **HIBCTL** register has been set may produce unexpected results.

Hibernation RTC Trim (HIBRTCT)

Base 0x400F.C000

Offset 0x024

Type RW, reset 0x0000.7FFF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TRIM	RW	0x7FFF	<p>RTC Trim Value</p> <p>This value is loaded into the RTC predivider every 64 seconds in RTC counter mode.</p> <p>In calendar mode, the value is loaded every 60 seconds.</p> <p>It is used to adjust the RTC rate to account for drift and inaccuracy in the clock source. Compensation can be adjusted by software by moving the default value of 0x7FFF up or down. Moving the value up slows down the RTC and moving the value down speeds up the RTC.</p>

Register 10: Hibernation RTC Sub Seconds (HIBRTCSS), offset 0x028

This register contains the RTC sub seconds counter and match values. The RTC value can be read by first reading the **HIBRTCC** register, reading the **RTCSSC** field in the **HIBRTCSS** register, and then rereading the **HIBRTCC** register. If the two values for **HIBRTCC** are equal, the read is valid.

Note: Except for the **HIBIO** and a portion of the **HIBIC** register, all other Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 565. The **HIBIO** register and bits **RSTWK**, **PADIOWK** and **WC** of the **HIBIC** register do not require waiting for write to complete. Because these registers are clocked by the system clock, writes to these registers/bits are immediate.

Writing to registers other than the **HIBCTL** and **HIBIM** before the **CLK32EN** bit in the **HIBCTL** register has been set may produce unexpected results.

Note: There is a minimum system clock rate of three times the HIB clock rate to properly read the **HIBRTCSS** register.

Hibernation RTC Sub Seconds (HIBRTCSS)

Base 0x400F.C000

Offset 0x028

Type RW, reset 0x0000.0000

31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
30:16	RTCSSM	RW	0x0000	RTC Sub Seconds Match The match value is contained in this field in one RTCOSC clock increments. A read returns the current seconds match value.
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14:0	RTCSSC	RO	0x0000	RTC Sub Seconds Count This field contains the sub second RTC count and is read as RTCOSC clock units. For the 32.768-kHz clock source, this would be in units of 1/32,768 seconds.

Register 11: Hibernation IO Configuration (HIBIO), offset 0x02C

This register is used to lock and unlock the external wake pin levels and enable the external RST pin and/or GPIO pins, Port K[7:4], as valid external WAKE sources.

Note: This register is in the system clock domain and does not require monitoring the WRC bit of the **HIBCTL** register before issuing a read or write of this register. Writes to this register are immediate.

Note: This register is in the core voltage domain and will not retain values over a hibernate cycle

4	WURSTEN	RW	0	Reset Wake Source Enable This register bit programming takes affect after WUUNLK has been set.
				Value Description 0 The \overline{RST} signal is not enabled as a wake source. 1 The \overline{RST} signal is enabled as a wake source.
3:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	WUUNLK	RW	0	I/O Wake Pad Configuration Enable
Value Description				
0				The I/O WAKE configuration set by the WURSTEN bit or in the GPIO module registers GPIOWAKEPEN and GPIOWAKELVL is ignored.
1				Implement the I/O WAKE configuration, level and enables for the external RST pin and/or GPIO wake-enabled pins.
Note: This bit must be cleared before issuing a hibernate request by setting the HIBREQ bit in the HIBCTL register.				

Register 12: Hibernation Data (HIBDATA), offset 0x030-0x06F

This address space is implemented as a 16x32-bit memory (64 bytes). It can be loaded by the system processor in order to store state information and retains its state during a power cut operation as long as a battery is present. **HIBDATA** registers 0x050 to 0x064 (upper eight words) may only be accessed using the processor privileged mode (default).

Note: Except for the **HIBIO** and a portion of the **HIBIC** register, all other Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 565. The **HIBIO** register and bits **RSTWK**, **PAD1OWK** and **WC** of the **HIBIC** register do not require waiting for write to complete. Because these registers are clocked by the system clock, writes to these registers/bits are immediate.

Writing to registers other than the **HIBCTL** and **HIBIM** before the **CLK32EN** bit in the **HIBCTL** register has been set may produce unexpected results.

Note: If V_{DD} is arbitrarily removed while a **HIBDATA** register write operation is in progress, the write operation must be retried after V_{DD} is reapplied.

5:0	SEC	RW	0	<p>Seconds</p> <p>This field holds the match value for seconds. The value is represented in hexadecimal.</p> <p>Bits 5:0 correspond to hex values from 0x0 to 0x3b (0 to 59 seconds). To ignore the hours match, write this field to all 1s.</p>

Register 19: Hibernation Calendar Match 1 (HIBCALM1), offset 0x334

The **Hibernation Calendar Match 1 (HIBCALM1)** register is used when the CALEN bit is set in the **HIBCALCTL** register. This register is loaded with desired match values for calendar mode. Once the **HIBCAL0/1** register values equal the **HIBCALM0/1** register values, the RTCALTO bit is set in the **HIBRIS** register.

Note: The day of week, month and year are not included in the match functionality.

Hibernation Calendar Match 1 (HIBCALM1)

Base 0x400F.C000
Offset 0x334
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4:0	DOM	RW	0	<p>Day of Month</p> <p>This field holds the match value for the day of the month in hexadecimal.</p> <p>Bits 4:0 correspond to hex values from 0x1 to 0xF (1 to 31 days). To disable match for the day of the month, the value 0x0 is used.</p>

Register 20: Hibernation Lock (HIBLOCK), offset 0x360

Writing 0xA335.9554 to the **HIBLOCK** register enables write access to the **HIBRTCLD**, **HIBCALLD0**, **HIBCALLD1** and Tamper registers. Writing any other value to the **HIBLOCK** register re-enables the locked state for register writes to all the other registers. Reading the **HIBLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **HIBLOCK** register returns 0x0000.0001 when locked; otherwise, the returned value is 0x0000.0000 (unlocked).

Hibernation Lock (HIBLOCK)

Bit/Field	Name	Type	Reset	Description
31:0	HIBLOCK	RW	0x0000	Hibernate Lock A write of 0xA335.9554 unlocks the HIBRCTL and Tamper registers.

Register 21: HIB Tamper Control (HIBTPCTL), offset 0x400

The Tamper Control (HIBTPCTL) register provides control of the module.

Note: Except for the **HIBIO** and a portion of the **HIBIC** register, all other Hibernation module registers are on the Hibernation module clock domain and have special timing requirements. Software should make use of the **WRC** bit in the **HIBCTL** register to ensure that the required timing gap has elapsed. If the **WRC** bit is clear, any attempted write access is ignored. See “Register Access Timing” on page 565. The **HIBIO** register and bits **RSTWK**, **PADIOWK** and **WC** of the **HIBIC** register do not require waiting for write to complete. Because these registers are clocked by the system clock, writes to these registers/bits are immediate.

Writing to registers other than the **HIBCTL** and **HIBIM** before the **CLK32EN** bit in the **HIBCTL** register has been set may produce unexpected results.

Note: Errant writes to the Tamper registers are protected by the Hibernate **HIBLOCK** register.

| 0 | RTCOSC is not available as a system clock source. |
| 1 | RTCOSC is available for use as a system clock source. |

8 Internal Memory

The TM4C129XKCZAD microcontroller comes with 256 KB of bit-banded SRAM, internal ROM, 512 KB of Flash memory, and 6KB of EEPROM.

The TM4C129XKCZAD microcontroller provides 512 KB of on-chip Flash memory. The Flash memory is configured as four banks of 8 K x 128 bits (4 * 128 KB total) which are two-way interleaved. Memory blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

The TM4C129XKCZAD microcontroller provides enhanced performance and power savings by implementation of two sets of instruction prefetch buffers. Each prefetch buffer is 2 x 256 bits and can be combined as a 4 x 256-bit prefetch buffer.

The EEPROM module provides a well-defined register interface to support accesses to the EEPROM with both a random access style of read and write as well as a rolling or sequential access scheme. A password model allows the application to lock one or more EEPROM blocks to control access on 16-word boundaries.

8.1 Block Diagram

Figure 8-1 on page 631 illustrates the internal memory and control structure . The dashed box in the figure indicate registers residing in the System Control module.

Figure 8-1. Internal Memory Block Diagram

8.2 Functional Description

This section describes the functionality of the SRAM, ROM, Flash, and EEPROM memories.

Note: The μDMA has read-only access to flash (in Run Mode only).

8.2.1 SRAM

The internal system SRAM of the Tiva™ C Series devices is located at address 0x2000.0000 of the device memory map. To reduce the number of time consuming read-modify-write (RMW) operations, ARM provides bit-banding technology in the processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation. The bit-band base is located at address 0x2200.0000.

The bit-band alias is calculated by using the formula:

```
bit-band alias = bit-band base + (byte offset * 32) + (bit number * 4)
```

For example, if bit 3 at address 0x2000.1000 is to be modified, the bit-band alias is calculated as:

```
0x2200.0000 + (0x1000 * 32) + (3 * 4) = 0x2202.000C
```

With the alias address calculated, an instruction performing a read/write to address 0x2202.000C allows direct access to only bit 3 of the byte at address 0x2000.1000.

For details about bit-banding, see “Bit-Banding” on page 118.

Note: The SRAM is implemented using four-way 32-bit wide interleaved SRAM banks (separate SRAM arrays) which allow for increased speed between memory accesses. When using interleaving, a write to one bank followed by a read of another bank can occur in successive clock cycles without incurring any delay. However, a write access that is followed immediately by a read access to the same bank incurs a stall of a single clock cycle.

The SRAM memory layout allows for multiple masters to access different SRAM banks simultaneously. If two masters attempt to access the same SRAM bank, the master with the higher priority gains access to the memory bus and the master with the lower priority is stalled by one wait state. If four masters attempt to access the same SRAM bank, access by the master with the lowest priority is delayed by three wait states. The CPU core always has the highest priority for SRAM memory accesses.

8.2.2 ROM

The internal ROM of the Tiva™ C Series device is located at address 0x0100.0000 of the device memory map. Detailed information on the ROM contents can be found in the *Tiva™ C Series TM4C129x ROM User’s Guide* (literature number [SPMU363](#)).

The ROM contains the following components:

- TivaWare™ Boot Loader and vector table
- TivaWare Peripheral Driver Library (DriverLib) release for product-specific peripherals and interfaces
- Advanced Encryption Standard (AES) cryptography tables
- Cyclic Redundancy Check (CRC) error detection functionality

The boot loader is used as an initial program loader (when the Flash location 0x0000.0004, the reset vector location is all 1s (that is, erased state of Flash)) as well as an application-initiated

firmware upgrade mechanism (by calling back to the boot loader). The Peripheral Driver Library APIs in ROM can be called by applications, reducing Flash memory requirements and freeing the Flash memory to be used for other purposes (such as additional features in the application). Advanced Encryption Standard (AES) is a publicly defined encryption standard used by the U.S. Government. Cyclic Redundancy Check (CRC) is a technique to validate whether a block of data has the same contents as when previously checked.

Note: CRC and AES software programs are available in TivaWare for backward-compatibility. A device that has enhanced CRC and AES integrated modules should utilize this hardware for best performance. Please refer to “Cyclical Redundancy Check (CRC)” on page 975 and “Advance Encryption Standard Accelerator (AES)” on page 984 for more information.

8.2.2.1 Boot Configuration

After Power-On-Reset (POR) and device initialization occurs, the hardware loads the stack pointer from either flash or ROM based on the presence of an application in flash and the state of the **EN** bit in the **BOOTCFG** register. If the flash address 0x0000.0004 contains an erased word (value 0xFFFF.FFFF) or the **EN** bit is of the **BOOTCFG** register is clear, the stack pointer and reset vector pointer are loaded from ROM at address 0x0100.0000 and 0x0100.0004, respectively. The boot loader executes and configures the available boot slave interfaces and waits for an external memory to load its software. The boot loader uses a simple packet interface to provide synchronous communication with the device. The speed of the boot loader is determined by the internal oscillator (PIOSC) frequency. The following serial interfaces can be used:

- UART0
- SSI0
- I²C0
- USB

If the check of the Flash at address 0x0000.0004 contains a valid reset vector value and the **EN** bit in the **BOOTCFG** register is set, the stack pointer and reset vector values are fetched from the beginning of flash. This application stack pointer and reset vector are loaded and the processor executes the application directly. Otherwise, the stack pointer and reset vector values are fetched from the beginning of ROM.

8.2.2.2 TivaWare Peripheral Driver Library

The TivaWare Peripheral Driver Library contains a file called `driverlib/rom.h` that assists with calling the peripheral driver library functions in the ROM. The detailed description of each function is available in the *Tiva™ C Series TM4C129x ROM User’s Guide (literature number [SPMU363](#))*. See the “Using the ROM” chapter of the *TivaWare™ Peripheral Driver Library for C Series User’s Guide (literature number [SPMU298](#))* for more details on calling the ROM functions and using `driverlib/rom.h`.

A table at the beginning of the ROM points to the entry points for the APIs that are provided in the ROM. Accessing the API through these tables provides scalability; while the API locations may change in future versions of the ROM, the API tables do not. The tables are split into two levels; the main table contains one pointer per peripheral which points to a secondary table that contains one pointer per API that is associated with that peripheral. The main table is located at 0x0100.0010, right after the Cortex-M4F vector table in the ROM.

DriverLib functions are described in detail in the *TivaWare™ Peripheral Driver Library for C Series User’s Guide (literature number [SPMU298](#))*.

Additional APIs are available for graphics and USB functions, but are not preloaded into ROM. The TivaWare Graphics Library provides a set of graphics primitives and a widget set for creating graphical

user interfaces on Tiva™ C Series microcontroller-based boards that have a graphical display (for more information, see the *TivaWare™ Graphics Library for C Series User's Guide* (*literature number SPMU300*)). The TivaWare USB Library is a set of data types and functions for creating USB Device, Host or On-The-Go (OTG) applications on Tiva™ C Series microcontroller-based boards (for more information, see the *TivaWare™ USB Library for C Series User's Guide* (*literature number SPMU297*))).

8.2.2.3 Advanced Encryption Standard (AES) Cryptography Tables

AES is a strong encryption method with reasonable performance and size. AES is fast in both hardware and software, is fairly easy to implement, and requires little memory. AES is ideal for applications that can use prearranged keys, such as setup during manufacturing or configuration. Four data tables used by the XySSL AES implementation are provided in the ROM. The first is the forward S-box substitution table, the second is the reverse S-box substitution table, the third is the forward polynomial table, and the final is the reverse polynomial table. See the *Tiva™ C Series TM4C129x ROM User's Guide* (*literature number SPMU363*) for more information on AES.

8.2.2.4 Cyclic Redundancy Check (CRC) Error Detection

The CRC technique can be used to validate correct receipt of messages (nothing lost or modified in transit), to validate data after decompression, to validate that Flash memory contents have not been changed, and for other cases where the data needs to be validated. A CRC is preferred over a simple checksum (for example, XOR all bits) because it catches changes more readily. When device initialization is executing from ROM, a CRC-32 validates the data being transferred into registers and memory. The CRC ensures no instructions were skipped in a sequence or no data was corrupted during transfer. See the *Tiva™ C Series TM4C129x ROM User's Guide* (*literature number SPMU363*) for more information on CRC.

8.2.3 Flash Memory

The Flash memory is configured in groups of four banks four banks of 8 K x 128 bits (4 * 128 KB total) which are two-way interleaved as shown below.

Figure 8-2. Flash Memory Configuration

The interleaved memory prefetches 256 bits at a time. The prefetch buffers allow the maximum performance of a 120 MHz CPU speed to be maintained with linear code or loops that fit within the prefetch buffer. It is recommended that code be compiled with switches set to eliminate "literals" as much as possible as a literal causes a flash access for that word and a stall for the wait states. Most compilers support transforming literals into "in-line" code, which executes faster in a system where the memory subsystem is slower than the CPU.

Because the memory is two-way interleaved and each bank individually is an 8-KB sector, when the user erases a sector, using the ERASE bits in the **Flash Memory Control (FMC)** register, it is a 16 KB erase. Erasing a block causes the entire contents of the block to be reset to all 1s.

8.2.3.1 Flash Configuration

Depending on the CPU frequency, the application must program the Flash clock high time (FBCHT), Flash Bank Clock Edge (FBCE) and Flash wait states (FWS) in the **Memory Timing Parameter Register 0 for Main Flash and EEPROM (MEMTIM0)**, System Control Module offset 0x0C0. The following table details the bit field values that are required for the given CPU frequency ranges.

Table 8-1. MEMTIM0 Register Configuration versus Frequency

CPU Frequency range (f) in MHz	Time Period Range (t) in ns	Flash Bank Clock High Time (FBCHT)	Flash Bank Clock Edge (FBCE)	Flash Wait States (FWS)
16	62.5	0x0	1	0x0
16 < f ≤ 40	62.5 > t ≥ 25	0x2	0	0x1
40 < f ≤ 60	25 > t ≥ 16.67	0x3	0	0x2
60 < f ≤ 80	16.67 > t ≥ 12.5	0x4	0	0x3
80 < f ≤ 100	12.5 > t ≥ 10	0x5	0	0x4

Table 8-1. MEMTIM0 Register Configuration versus Frequency (continued)

CPU Frequency range (f) in MHz	Time Period Range (t) in ns	Flash Bank Clock High Time (FBCHT)	Flash Bank Clock Edge (FBCE)	Flash Wait States (FWS)
100 < f ≤ 120	10 > t ≥ 8.33	0x6	0	0x5

To update the **MEMTIM0** register with the new Flash configuration values, the **MEMTIM0** bit should be set in the **Run and Sleep Mode Configuration Register (RSCLKCFG)**, System Control offset 0x0B0.

Note: The associated Flash and EEPROM fields in the **MEMTIM0** register must be programmed to the same values. For example, the **FWS** field must be programmed to the same value as the **EWS** field.

8.2.3.2 Prefetch Buffers

The prefetch buffers can exist as a single set of 2x256-bit buffers or 4x256-bit buffers depending on the **SPFE** bit programmed in the **Flash Configuration Register (FLASHCONF)** register, offset 0xFC8. At reset, all four buffers are enabled. The buffers are filled using a "least-recently-used" (LRU) method. When operating in a single set buffer configuration, the two, 256-bit buffers create a deterministic configuration as each "next" write is sent to the previous buffer that was written. Figure 8-3 on page 636 depicts the single 256-bit buffer set. The single prefetch buffer set should only be used when the code execution must be purely deterministic for the number of clock cycles it takes to execute. Utilizing the four prefetch buffer configuration is the preferred method of configuration.

Figure 8-3. Single 256-Bit Prefetch Buffer Set

		255	224 223	192 191	160 159	128 127	96 95	64 63	32 31	0
Prefetch Buffer 0	TAG	WORD 7	WORD 6	WORD 5	WORD 4	WORD 3	WORD 2	WORD 1	WORD 0	
Prefetch Buffer 1	TAG	WORD 7	WORD 6	WORD 5	WORD 4	WORD 3	WORD 2	WORD 1	WORD 0	

When the buffers are configured as four, 256-bit buffers, they function as one set, with one of the four buffers tagged as the LRU and the next to be used when an auto-fill or miss occurs.

Figure 8-4. Four 256-Bit Prefetch Buffer Configuration

		255	224 223	192 191	160 159	128 127	96 95	64 63	32 31	0
Prefetch Buffer 0	TAG	WORD 7	WORD 6	WORD 5	WORD 4	WORD 3	WORD 2	WORD 1	WORD 0	
Prefetch Buffer 1	TAG	WORD 7	WORD 6	WORD 5	WORD 4	WORD 3	WORD 2	WORD 1	WORD 0	
Prefetch Buffer 2	TAG	WORD 7	WORD 6	WORD 5	WORD 4	WORD 3	WORD 2	WORD 1	WORD 0	
Prefetch Buffer 3	TAG	WORD 7	WORD 6	WORD 5	WORD 4	WORD 3	WORD 2	WORD 1	WORD 0	

The address of the auto-fill is stored in this tag register so that address violations can be identified immediately and miss processing can begin directly. Every ICODE access is checked against valid tags to see if the target word is already in the buffers.

If there is a hit, the target word is immediately sent to the CPU with no wait states. If there is a miss, then the prefetch buffer is invalidated and the miss is processed as a 256-bit read from the flash

subsystem to fill the next, least-recently used prefetch buffer. Two memory banks are read in parallel to retrieve 256-bits worth of data.

If an auto-fill has been started and a miss occurs, the auto-fill completes before the miss is processed. If an auto-fill occurs that hits the prefetch buffer being processed for the auto-fill, then the ICODE bus is stalled until the auto fill is complete and new entry can be accessed. For an instruction miss, access to the flash bank starts immediately after the address is available provided the flash sub-system is not already processing a DCODE bus access or a PROGRAM/ERASE operation in the same banks. The target word is passed to the CPU one cycle after it is written to the prefetch buffer.

Figure 8-5 on page 637 shows the timing diagram for a hit in the prefetch buffer.

Figure 8-5. Single Cycle Access, 0 Wait States

The Flash memory can operate at the CPU clock speed with zero-wait-state accesses when data is resident in the prefetch buffers. When an access does not hit in the prefetch buffer, there is a delay that is incurred while the data is transferred from the Flash. This delay is dependent on the programmed CPU frequency. Refer to Table 8-1 on page 635 for required CPU frequency versus programmed wait-state delay information. Figure 8-6 on page 638 depicts the events that occur as the CPU steps through the words in the prefetch buffer that has just been loaded until it reaches the end of the current prefetch line. The notable events are as follows (refer to Figure 8-6 on page 638):

- EVENT A: When the CPU has a miss in the prefetch buffer, a line is fetched from Flash. The target word is written to the prefetch buffer and sent to the CPU one cycle after.
- EVENT B: When the CPU reaches Word 3, the next 256-bit buffer line is fetched, resulting in a zero-wait-state access of next line's Word 0
- EVENT C: After this word, if the CPU is still executing sequentially, Word 0 of the next buffer line that was fetched is sent to the CPU, with zero-wait-state delay
- EVENT D: Word 0 from the second fetch that occurred is sent to the CPU

Figure 8-6. Prefetch Fills from Flash

Note that if the CPU target word is beyond Word 2 (Word 3 through Word 7) then the next prefetch fill begins immediately and, depending on the CPU frequency, a delay is incurred between CPU access of Word 7 and Word 0 of the next line.

Note: For optimal prefetch buffer performance, align application code/branches on 8-word boundaries.

The prefetch buffers can be forced ON and OFF by setting the `FPFON` and `FPFOFF` bits in the **Flash Configuration (FLASHCONF)** register at 0xFC8. If the application sets the `FPFON` or `FPFOFF` bit while the CPU is currently reading or writing to Flash, the prefetch buffer action of turning on or off happens only after the Flash operation has completed. This feature can be used in test modes when determining optimum memory configuration for code.

Prefetch buffer valid tags can be cleared in the following ways:

- Any **Flash Configuration (FLASHCONF)** register changes, such as:
 - Disabling the prefetch buffer by setting the `FPFOFF` bit
 - Setting the `CLRTV` bit to clear the prefetch buffer tags
- A system reset
- ROM accesses
- Error during ICODE accesses
- System aborts
- Mirror mode changes

Note: If the prefetch buffers are enabled and application code branches to a location other than flash memory, the prefetch tags need to be cleared upon returning to flash code execution. Prefetch tags can be cleared by setting the `CLRTV` bit in the **FLASHCONF** register.

8.2.3.3 Flash Mirror Mode

Flash mirroring allows multiple copies of software to exist in Flash simultaneously. The software can run from the lower banks at the same time software is updating a mirrored copy on the upper bank. In addition to the data, the boot loader in both the lower and upper banks must be mirrored while programming the flash contents. If data needs to be recovered, a hot swap can be done by setting the `FMME` bit in the **FLASHCONF** register to ensure the flash banks are idle during the swap. The prefetch buffers must be invalidated during the execution of a hot swap. Next, the address translation logic decodes up to 256 KB from the upper banks to the lower banks. Once the banks are swapped, the mirrored flash image is then used. The address translation logic translates the

address to the upper banks until the next swap. Figure 8-7 on page 639 depicts the configuration necessary when executing Flash mirroring.

Note: After a mirror mode has been executed and the code locations have been swapped from the upper memory banks to the lower, the application can continue to read from the lower memory bank address locations. However, when erasing or programming the swapped memory, the application must use the "real" upper memory address of the code before it was swapped. For example, in Figure 8-7 on page 639, when the yellow highlighted location 0x00.3FE8 is swapped with 0x04.3FE8 the application's next read location is 0x00.3FEC. However, if the application were to program or erase the next location it would need to write or erase location 0x04.3FEC.

Figure 8-7. Mirror Mode Function

8.2.3.4 Protected Flash Memory Registers

The user is provided execution protection through of 32-bit wide registers. The policy for each protection form is controlled by individual bits (per policy per block) in the **FMPPEn** and **FMPREn** registers.

- **Flash Memory Protection Program Enable (FMPPEn):** In the Flash, 16-KB blocks can be individually protected from being programmed or erased. Because each bit of the **FMPPE** register represents a 2-KB block, the application must clear all the bits in one byte to protect one 16-KB block. Execute-only protection can only be programmed in 16-KB increments. For example, to protect the first 16-KB block, bits [7:0] all need to be set to 0s. When bits in the **FMPPEn** register are set, the corresponding block may be programmed (written) or erased. When bits are cleared, the corresponding block may not be changed. When a block is protected by clearing bits in both **FMPPEn** and **FMPREn** registers, execute-only protection can be achieved.
- **Flash Memory Protection Read Enable (FMPREn):** If a bit is set in this register, the corresponding block may be executed or read by software or debuggers. If a bits in this register are cleared and the same block in the **FMPREn** register is cleared, the corresponding block may

only be executed, and contents of the memory block are prohibited from being read as data. **FMPREn** protection can be programmed in 2-KB increments, unlike the **FMPPEn**, which must be programmed in 16-KB increments. However, if an application does want to read-protect a 16-KB block, eight bits need to be written from 1s to 0s.

The policies may be combined as shown in Table 8-2 on page 640.

Table 8-2. Flash Memory Protection Policy Combinations

FMPPEn	FMPREn	Protection
0	0	Execute-only protection. The block may only be executed and may not be written or erased. This mode is used to protect code.
1	0	The block may be written, erased or executed, but not read. This combination is unlikely to be used.
0	1	Read-only protection. The block may be read or executed but may not be written or erased. This mode is used to lock the block from further modification while allowing any read or execute access.
1	1	No protection. The block may be written, erased, executed or read.

A Flash memory access that attempts to read a read-protected block (**FMPREn** bit is clear) is prohibited and generates a bus fault. A Flash memory access that attempts to program or erase a program-protected block (**FMPPEn** bit is clear) is prohibited and can optionally generate an interrupt (by setting the **AMASK** bit in the **Flash Controller Interrupt Mask (FCIM)** register) to alert software developers of poorly behaving software during the development and debug phases.

The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. These settings create a policy of open access and programmability. The register bits may be changed by clearing the specific register bit. The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a any simulated power-on-reset (SIM_POR) event. The changes are committed using the **Flash Memory Control (FMC)** register. Details on programming these bits are discussed in “Non-Volatile Register Programming-- Flash Memory Resident Registers” on page 643.

8.2.3.5 Execute-Only Protection

Execute-only protection prevents both modification and visibility to a protected flash block. This mode is intended to be used in situations where a device requires debug capability, yet portions of the application space must be protected from external access. An example of this is a company that wishes to sell Tiva™ C Series devices with their proprietary software preprogrammed, yet allow the end user to add custom code to an unprotected region of the flash (such as a motor control module with a customizable motor configuration section in flash).

Literal data introduces a complication to the protection mechanism. When C code is compiled and linked, literal data (constants, and so on) is typically placed in the text section, between functions, by the compiler. The literal data is accessed at run time through the use of the LDR instruction, which loads the data from memory using a PC-relative memory address. The execution of the LDR instruction generates a read transaction across the Cortex-M3's DCode bus, which is subject to the execute-only protection mechanism. If the accessed block is marked as execute only, the transaction is blocked, and the processor is prevented from loading the constant data and, therefore, inhibiting correct execution. Therefore, using execute-only protection requires that literal data be handled differently. There are three ways to address this:

1. Use a compiler that allows literal data to be collected into a separate section that is put into one or more read-enabled flash blocks. Note that the LDR instruction may use a PC-relative address,

in which case the literal pool cannot be located outside the span of the offset, or the software may reserve a register to point to the base address of the literal pool and the LDR offset is relative to the beginning of the pool.

2. Use a compiler that generates literal data from arithmetic instruction immediate data and subsequent computation.
3. Use method 1 or 2, but in assembly language, if the compiler does not support either method.

8.2.3.6 Read-Only Protection

Read-only protection prevents the contents of the flash block from being re-programmed, while still allowing the content to be read by processor or the debug interface. Note that if a **FMPREn** bit is cleared, all read accesses to the Flash memory block are disallowed, including any data accesses. Care must be taken not to store required data in a Flash memory block that has the associated **FMPREn** bit cleared.

The read-only mode does not prevent read access to the stored program, but it does provide protection against accidental (or malicious) erasure or programming. Read-only is especially useful for utilities like the boot loader when the debug interface is permanently disabled. In such combinations, the boot loader, which provides access control to the Flash memory, is protected from being erased or modified.

8.2.3.7 Permanently Disabling Debug

For extremely sensitive applications, the debug interface to the processor and peripherals can be permanently disabled, blocking all accesses to the device through the JTAG or SWD interfaces. With the debug interface disabled, it is still possible to perform standard IEEE instructions (such as boundary scan operations), but access to the processor and peripherals is blocked.

The **DBG0** and **DBG1** bits of the **Boot Configuration (BOOTCFG)** register control whether the debug interface is turned on or off.

The debug interface should not be permanently disabled without providing some mechanism, such as the boot loader, to provide customer-installable updates or bug fixes. Disabling the debug interface is permanent and cannot be reversed.

8.2.3.8 Interrupts

The Flash memory controller can generate interrupts when the following conditions are observed:

- Programming Interrupt: Signals when a program or erase action is complete. (**PRIS**).
- Access Interrupt: Signals when a program or erase action has been attempted on a 16-kB block of memory that is protected by its corresponding **FMPPEn** bit. (**ARIS**).
- EEPROM Interrupt
- Pump Voltage Interrupt: Indicates if the regulated voltage of the pump went out of specification during a Flash operation and the operation was terminated. (**VOLTRIS**).
- Invalid Data Interrupt: Signals when a bit in Flash that was previously programmed as a 0 is now requested to be programmed as a 1. (**INVDRIS**).
- ERASE Operation Interrupt: Indicates an ERASE operation failed. (**ERRIS**).

The interrupt events that can trigger a controller-level interrupt are defined in the **Flash Controller Masked Interrupt Status (FCMIS)** register (see page 661) by setting the corresponding MASK bits. If interrupts are not used, the raw interrupt status is always visible via the **Flash Controller Raw Interrupt Status (FCRIS)** register (see page 658).

Interrupts are always cleared (for both the **FCMIS** and **FCRIS** registers) by writing a 1 to the corresponding bit in the **Flash Controller Masked Interrupt Status and Clear (FCMISC)** register (see page 663).

8.2.3.9 μDMA

The μDMA can be programmed to read from Flash. The **Flash DMA Address Size (FLASHDMASZ)** register configures 2-KB regions of Flash that can be accessed by the μDMA. The starting address for this μDMA-accessible region is defined in the **Flash DMA Starting Address (FLASHDMAST)** register. When the **DFA** bit is set in the **FLASHPP** register, the μDMA can access the enabled region configured by the **FLASHDMASZ** and **FLASHDMAST** registers. The μDMA checks the **Flash Protection Program Enable n (FMPPEn)** registers for masked 2-KB Flash regions before initiating the transfer. If the access is out of range, then a bus fault is generated.

Note: The μDMA can access Flash in Run Mode only (not available in low power modes).

8.2.3.10 Flash Memory Programming

The Tiva™ C Series devices provide a user-friendly interface for Flash memory programming. All erase/program operations are handled via three registers: **Flash Memory Address (FMA)**, **Flash Memory Data (FMD)**, and **Flash Memory Control (FMC)**. Note that if the debug capabilities of the microcontroller have been deactivated, resulting in a "locked" state, a recovery sequence must be performed in order to reactivate the debug module. See "Recovering a "Locked" Microcontroller" on page 223.

When a Flash memory operation write, page erase, or mass erase is executed in a Flash bank, access to that particular bank pair is inhibited. As a result, instruction and literal fetches to the bank pair are held off until the Flash memory operation is complete. If instruction execution is required during a Flash memory operation, the code that is executing must be placed in SRAM and executed from there while the flash operation is in progress.

Note: When programming Flash memory, the following characteristics of the memory must be considered:

- Only an erase can change bits from 0 to 1.
- A write can only change bits from 1 to 0. If the write attempts to change a 0 to a 1, the write fails and no bits are changed.
- All Flash operations are completed before entering sleep or deep sleep.

To program a 32-bit word

1. Write source data to the **FMD** register.
2. Write the target address to the **FMA** register.
3. Write the Flash memory write key and the **WRITE** bit (a value of 0xA442.0001) to the **FMC** register. The write key may be 0xA442 or the value programmed into the **FLPEKEY** register depending on the **KEY** value in the **BOOTCFG** register. See page 701 and page 668 for more information.

4. Poll the **FMC** register until the **WRITE** bit is cleared.

To perform an erase of a 16-KB sector

1. Write the 16-KB aligned address to the **FMA** register.
2. Write the Flash memory write key and the **ERASE** bit to the **FMC** register.
3. Poll the **FMC** register until the **ERASE** bit is cleared or, alternatively, enable the programming interrupt using the **PMASK** bit in the **FCIM** register.

To perform a mass erase of the Flash memory

1. Write the Flash memory write key and the **MERASE** bit to the **FMC** register.
2. Poll the **FMC** register until the **MERASE** bit is cleared or, alternatively, enable the programming interrupt using the **PMASK** bit in the **FCIM** register.

8.2.3.11 32-Word Flash Memory Write Buffer

A 32-word write buffer provides the capability to perform faster write accesses to the Flash memory by programming two 32-bit words at a time, allowing 32 words to be programmed in the same time as 16 would take using the method described above. The data for the buffered write is written to the **Flash Write Buffer (FWBn)** registers.

The registers are 32-word aligned with Flash memory, and therefore the register **FWB0** corresponds with the address in **FMA** where bits [6:0] of **FMA** are all 0. **FWB1** corresponds with the address in **FMA** + 0x4 and so on. Only the **FWBn** registers that have been updated since the previous buffered Flash memory write operation are written. The **Flash Write Buffer Valid (FWBVAL)** register shows which registers have been written since the last buffered Flash memory write operation. This register contains a bit for each of the 32 **FWBn** registers, where bit[n] of **FWBVAL** corresponds to **FWBn**. The **FWBn** register has been updated if the corresponding bit in the **FWBVAL** register is set.

To program 32 words with a single buffered Flash memory write operation

1. Write the source data to the **FWBn** registers.
2. Write the target address to the **FMA** register. This must be a 32-word aligned address (that is, bits [6:0] in **FMA** must be 0s).
3. Write the Flash memory write key and the **WRBUF** bit to the **FMC2** register.
4. Poll the **FMC2** register until the **WRBUF** bit is cleared or wait for the **PMIS** interrupt to be signaled.

8.2.3.12 Non-Volatile Register Programming-- Flash Memory Resident Registers

Note: The **Boot Configuration (BOOTCFG)** register requires a POR before the committed changes take effect.

This section discusses how to update registers that are resident within the Flash memory. These registers exist in a separate space from the main Flash memory array and are not affected by an ERASE or MASS ERASE operation. The bits in these registers can be changed from 1 to 0 with a commit operation. The register contents are unaffected by any reset condition except power-on reset, which returns the register contents to 0xFFFF.FFFE for the **Boot Configuration (BOOTCFG)** register and 0xFFFF.FFFF for all others. By committing the register values using the **COMT** bit in the **Flash Memory Control (FMC)** register, the register contents become non-volatile and are therefore

retained following power cycling. Once the register contents are committed, the only way to restore the factory default values is to perform the sequence described in “Recovering a “Locked” Microcontroller” on page 223.

All of the **FMPREn** and **USER_REGn** registers, in addition to the **BOOTCFG** register can be committed in non-volatile memory. The **FMPREn**, **FMPPEn**, and **USER_REGn** registers can be tested before being committed; the **BOOTCFG** register cannot. To program the **BOOTCFG** register, the value must be written into the **Flash Memory Data (FMD)** register before it is committed. The **BOOTCFG** configuration cannot be tried and verified before committing to non-volatile memory.

Important: All Flash memory resident registers can only have bits changed from 1 to 0 by user programming. The **FMPREn** and **BOOTCFG** registers can be committed multiple times, but the **USER_REGn** registers can only be committed once, after the entire register has been set to 1s. After being committed, the **USER_REGn** registers can only be returned to their factory default values of all 1s by performing the sequence described in “Recovering a “Locked” Microcontroller” on page 223. The mass erase of the main Flash memory array caused by the sequence is performed prior to restoring these registers.

Table 8-3 on page 644 provides the **FMA** address required for commitment of each of the registers and the source of the data to be written when the **FMC** register is written with a key value of 0xA442 or the **PEKEY** value of the **FLPEKEY** register. The key value used is determined by the **KEY** bit in the **BOOTCFG** register at reset. If the **KEY** value is 0x0, the **PEKEY** value in the **FLPEKEY** register is used for commits in the **FMC/FMC2** register. If the **KEY** value is 0x1, the value 0xA442 is used as the **WRKEY** in the **FMC/FMC2** register. If the After writing the **COMT** bit, the user may poll the **FMC** register to wait for the commit operation to complete.

Table 8-3. User-Programmable Flash Memory Resident Registers

Register to be Committed	FMA Value	Data Source
FMPRE0	0x0000.0000	FMPRE0
FMPRE1	0x0000.0002	FMPRE1
FMPRE2	0x0000.0004	FMPRE2
FMPRE3	0x0000.0006	FMPRE3
FMPRE4	0x0000.0008	FMPRE4
FMPRE5	0x0000.000A	FMPRE5
FMPRE6	0x0000.000C	FMPRE6
FMPRE7	0x0000.000E	FMPRE7
FMPPE0	0x0000.0001	FMPPE0
FMPPE1	0x0000.0003	FMPPE1
FMPPE2	0x0000.0005	FMPPE2
FMPPE3	0x0000.0007	FMPPE3
FMPPE4	0x0000.0009	FMPPE4
FMPPE5	0x0000.000B	FMPPE5
FMPPE6	0x0000.000D	FMPPE6
FMPPE7	0x0000.000F	FMPPE7
USER_REG0	0x8000.0000	USER_REG0
USER_REG1	0x8000.0001	USER_REG1
USER_REG2	0x8000.0002	USER_REG2
USER_REG3	0x8000.0003	USER_REG3

Table 8-3. User-Programmable Flash Memory Resident Registers (continued)

Register to be Committed	FMA Value	Data Source
BOOTCFG	0x7510.0000	FMD

8.2.4 EEPROM

The TM4C129XKCZAD microcontroller includes an EEPROM with the following features:

- 6Kbytes of memory accessible as 1536 32-bit words
- 96 blocks of 16 words (64 bytes) each
- Built-in wear leveling
- Access protection per block
- Lock protection option for the whole peripheral as well as per block using 32-bit to 96-bit unlock codes (application selectable)
- Interrupt support for write completion to avoid polling
- Endurance of 500K writes (when writing at fixed offset in every alternate page in circular fashion) to 15M operations (when cycling through two pages) per each 2-page block.

8.2.4.1 Functional Description

The EEPROM module provides a well-defined register interface to support accesses to the EEPROM with both a random access style of read and write as well as a rolling or sequential access scheme.

A protection mechanism allows locking EEPROM blocks to prevent writes under a set of circumstances as well as reads under the same or different circumstances. The password model allows the application to lock one or more EEPROM blocks to control access on 16-word boundaries.

Blocks

There are 96 blocks of 16 words each in the EEPROM. These are readable and writable as words. Bytes and half-words can be read, and these accesses do not have to occur on a word boundary. The entire word is read and any unneeded data is simply ignored. The EEPROM blocks are writable only on a word basis. To write a byte, it is necessary to read the word value, modify the appropriate byte, and write the word back.

Each block is addressable as an offset within the EEPROM, using a block select register. Each word is offset addressable within the selected block.

The current block is selected by the **EEPROM Current Block (EEBLOCK)** register. The current offset is selected and checked for validity by the **EEPROM Current Offset (EEOFFSET)** register. The application may write the **EEOFFSET** register any time, and it is also automatically incremented when the **EEPROM Read-Write with Increment (EERDWRINC)** register is accessed. However, the **EERDWRINC** register does not increment the block number, but instead wraps within the block.

Blocks are individually protectable. Attempts to read from a block for which the application does not have permission return 0xFFFF.FFFF. Attempts to write into a block for which the application does not have permission results in an error in the **EEPROM Done Status (EEDONE)** register.

Timing Considerations

After enabling or resetting the EEPROM module, software must wait until the WORKING bit in the **EEDONE** register is clear before accessing any EEPROM registers.

Note: Software must ensure there are no Flash memory writes or erases pending before performing an EEPROM operation. When the **FMC** register reads as 0x0000.00000 and the WRBUF bit of the **FMC2** register is clear, there are no Flash memory writes or erases pending.

EEPROM operations must be completed before entering Sleep or Deep-Sleep mode. Ensure the EEPROM operations have completed by checking the **EEPROM Done Status (EEDONE)** register before issuing a WFI instruction to enter Sleep or Deep-Sleep.

Writes to words within a block are delayed by a variable amount of time. The application may use an interrupt to be notified when the write is done, or alternatively poll for the done status in the **EEDONE** register. The variability ranges from the write timing of the EEPROM to the erase timing of EEPROM, where the erase timing is less than the write timing of most external EEPROMs.

Depending on the CPU frequency, the application must program the EEPROM Clock High Time (**EBCHT**), EEPROM Bank Clock Edge (**EBCE**) and the EEPROM Wait States (**EWS**) in the **Memory Timing Parameter Register 0 for Main Flash and EEPROM (MEMTIM0)** register at System Control Module offset 0x0C0.

Table 8-4. MEMTIM0 Register Configuration versus Frequency

CPU Frequency range (f) in MHz	Time Period Range (t) in ns	EEPROM Bank Clock High Time (EBCHT)	EEPROM Bank Clock Edge (EBCE)	EEPROM Wait States (EWS)
16	62.5	0x0	1	0x0
16 < f ≤ 40	62.5 > t ≥ 25	0x2	0	0x1
40 < f ≤ 60	25 > t ≥ 16.67	0x3	0	0x2
60 < f ≤ 80	16.67 > t ≥ 12.5	0x4	0	0x3
80 < f ≤ 100	12.5 > t ≥ 10	0x5	0	0x4
100 < f ≤ 120	10 > t ≥ 8.33	0x6	0	0x5

Note: The associated Flash and EEPROM fields in the **MEMTIM0** register must be programmed to the same values. For example, the **FWS** field must be programmed to the same value as the **EWS** field.

Locking and Passwords

The EEPROM can be locked at both the module level and the block level. The lock is controlled by a password that is stored in the **EEPROM Password (EEPASSn)** registers and can be any 32-bit to 96-bit value other than all 1s. Block 0 is the master block, the password for block 0 protects the control registers as well as all other blocks. Each block can be further protected with a password for that block.

If a password is registered for block 0, then the whole module is locked at reset. As a result, the **EEBLOCK** register cannot be changed from 0 until block 0 is unlocked.

A password registered with any block, including block 0, allows for protection rules that control access of that block based on whether it is locked or unlocked. Generally, the lock can be used to prevent write accesses when locked or can prevent read and write accesses when locked.

All password protected blocks are locked at reset. To unlock a block, the correct password value must be written to the **EEPROM Unlock (EEUNLOCK)** register by writing to it once, twice, or three

times, depending on the size of the password. A block or the module may be re-locked by writing 0xFFFF.FFFF to the **EEUNLOCK** register because 0xFFFF.FFFF is not a valid password.

Protection and Access Control

The PROT protection field in the **EEPROM Protection (EEPROT)** register provides discrete control of read and write access for each block which allows various protection models per block. The protection configurations allowed are as follows:

- PROT = 0x0
 - Without password: Readable and writable at any time. This mode is the default when there is no password.
 - With password: Readable, but only writable when unlocked by the password. This mode is the default when there is a password.
- PROT = 0x1
 - With password: Readable or writable only when unlocked.
 - This value has no meaning when there is no password.
- PROT = 0x2
 - Without password: Readable but not writable.
 - With password: Readable only when unlocked, not writable under any conditions.

Additionally, access protection may be applied based on the processor mode. This configuration allows for supervisor-only access or supervisor and user access, which is the default. Supervisor-only access mode also prevents access by the µDMA and Debugger.

Additionally, the master block may be used to control access protection for the protection mechanism itself. If access control for block 0 is for supervisor only, then the whole module may only be accessed in supervisor mode.

Hidden Blocks

Hiding provides a temporary form of protection. Every block except block 0 can be hidden, which prevents all accesses until the next reset.

This mechanism can allow a boot or initialization routine to access some data which is then made inaccessible to all further accesses. Because boot and initialization routines control the capabilities of the application, hidden blocks provide a powerful isolation of the data when debug is disabled.

A typical use model would be to have the initialization code store passwords, keys, and/or hashes to use for verification of the rest of the application. Once performed, the block is then hidden and made inaccessible until the next reset which then re-enters the initialization code.

Power and Reset Safety

Once the **EEDONE** register indicates that a location has been successfully written, the data is retained until that location is written again. There is no power or reset race after the **EEDONE** register indicates a write has completed.

Interrupt Control

The EEPROM module allows for an interrupt when a write completes to prevent the use of polling. The interrupt can be used to drive an application ISR which can then write more words or verify completion. The interrupt mechanism is used any time the **EEDONE** register goes from working to done, whether because of an error or the successful completion of a program or erase operation. This interrupt mechanism works for data writes, writes to password and protection registers, and mass erase using the **EEPROM Debug Mass Erase (EEDBGME)** register. The EEPROM interrupt is signaled to the core using the Flash memory interrupt vector. Software can determine that the source of the interrupt was the EEPROM by examining bit 2 of the **Flash Controller Masked Interrupt Status and Clear (FCMISC)** register.

Theory of Operation

The EEPROM operates using a traditional bank model which implements EEPROM-type cells, but uses sector erase. Additionally, words are replicated in the blocks to allow 500K+ erase cycles when needed, which means that each word has a latest version. As a result, a write creates a new version of the word in a new location, making the previous value obsolete. When a block runs out of room to store the latest version of a word, a copy buffer is used. The copy buffer copies the latest words of each block. The original block is then erased. Finally, the copy buffer contents are copied back to the block.

The EEPROM module includes functionality to prevent data corruption due to power-loss or a brown-out event during programming or erase operations. These conditions prevent corruption of non-targeted memory areas but cannot guarantee that the operation is completed successfully. Refer to “EEPROM” on page 2123 for important timing information on EEPROM protection. The EEPROM mechanism properly tracks all state information to provide complete safety and protection. Although it should not normally be possible, errors during programming can occur in certain circumstances, for example, the voltage rail dropping during programming. In these cases, the **EESUPP** register can be used to know if a program or an erase had failed.

Debug Mass Erase

The EEPROM debug mass erase allows the developer to mass erase the EEPROM. For the mass erase to occur correctly, there can be no active EEPROM operations. After the last EEPROM operation, the application must ensure that no EEPROM registers are updated, including modifying the **EEBLOCK** and the **EEOFSET** registers without doing an actual read or write operation. To hold off these operations, the application should reset the EEPROM module by setting the **R0** bit in the **EEPROM Software Reset (SREEPROM)** register, wait until **WORKING** bit in the **EEPROM Done Status (EEDONE)** register is clear, and then enable the debug mass erase by setting the **ME** bit in the **EEPROM Debug Mass Erase (EEDBGME)** register.

Error During Programming

Operations such as data-write, password set, protection set, and copy buffer erase may perform multiple operations. For example, a normal write performs two underlying writes: the control word write and the data write. If the control word writes but the data fails (for example, due to a voltage drop), the overall write fails with indication provided in the **EEDONE** register. Failure and the corrective action is broken down by the type of operation:

- If a normal write fails such that the control word is written but the data fails to write, the safe course of action is to retry the operation once the system is otherwise stable, for example, when the voltage is stabilized. After the retry, the control word and write data are advanced to the next location.

- If a password or protection write fails, the safe course of action is to retry the operation once the system is otherwise stable. In the event that multi-word passwords may be written outside of a manufacturing or bring-up mode, care must be taken to ensure all words are written in immediate succession. If not, then partial password unlock would need to be supported to recover.
- If the word write requires the block to be written to the copy buffer, then it is possible to fail or lose power during the subsequent operations. A control word mechanism is used to track what step the EEPROM was in if a failure occurs. If not completed, the **EESUPP** register indicates the partial completion.

After a reset and prior to writing any data to the EEPROM, software must read the **EESUPP** register and check for the presence of any error condition which may indicate that a write or erase was in progress when the system was reset due to a voltage drop. If either the **PRETRY** or **ERETRY** bits are set, the peripheral should be reset by setting and then clearing the **R0** bit in the **EEPROM Software Reset (SREEPROM)** register and waiting for the **WORKING** bit in the **EEDONE** register to clear before again checking the **EESUPP** register for error indicators. This procedure should allow the EEPROM to recover from the write or erase error. In very isolated cases, the **EESUPP** register may continue to register an error after this operation, in which case the reset should be repeated. After recovery, the application should rewrite the data which was being programmed when the initial failure occurred.

Endurance

Endurance is per meta-block which is 8 blocks. Endurance is measured in two ways:

1. To the application, it is the number of writes that can be performed.
2. To the microcontroller, it is the number of erases that can be performed on the meta-block.

Because of the second measure, the number of writes depends on how the writes are performed. For example:

- One word can be written more than 500K times, but, these writes impact the meta-block that the word is within. As a result, writing one word 500K times, then trying to write a nearby word 500K times is not assured to work. To ensure success, the words should be written more in parallel.
- All words can be written in a sweep with a total of more than 500K sweeps which updates all words more than 500K times.
- Different words can be written such that any or all words can be written more than 500K times when write counts per word stay about the same. For example, offset 0 could be written 3 times, then offset 1 could be written 2 times, then offset 2 is written 4 times, then offset 1 is written twice, then offset 0 is written again. As a result, all 3 offsets would have 4 writes at the end of the sequence. This kind of balancing within 7 writes maximizes the endurance of different words within the same meta-block.

8.2.4.2 EEPROM Initialization and Configuration

Before writing to any EEPROM registers, the clock to the EEPROM module must be enabled through the **EEPROM Run Mode Clock Gating Control (RCGCEEPROM)** register (see page 416) and the following initialization steps must be executed:

1. Insert delay (6 cycles plus function call overhead).

2. Poll the WORKING bit in the **EEPROM Done Status (EEDONE)** register until it is clear indicating that the EEPROM has completed its power-on initialization. When WORKING=0, continue.
3. Read the PRETRY and ERETRY bits in the **EEPROM Support Control and Status (EESUPP)** register. If either of the bits are set, return an error, else continue.
4. Reset the EEPROM module using the **EEPROM Software Reset (SREEPROM)** register at offset 0x558 in the System Control register space.
5. Insert delay (6 cycles plus function call overhead).
6. Poll the WORKING bit in the **EEPROM Done Status (EEDONE)** register to determine when it is clear. When WORKING=0, continue.
7. Read the PRETRY and ERETRY bits in the **EESUPP** register. If either of the bits are set, return an error, else the EEPROM initialization is complete and software may use the peripheral as normal.

Note: Failure to perform these initialization steps after a reset may lead to incorrect operation or permanent data loss if the EEPROM is later written.

Note: If the PRETRY or ERETRY bits are set in the **ESUPP** register, the EEPROM was unable to recover its state. If power is stable when this occurs, this indicates a fatal error and is likely an indication that the EEPROM memory has exceeded its specified lifetime write/erase specification. If the supply voltage is unstable when this return code is observed, retrying the operation once the voltage is stabilized may clear the error.

The EEPROM initialization function code is named EEPROMInit() in TivaWare, which can be downloaded from <http://www.ti.com/tivaware>.

8.2.5 Bus Matrix Memory Accesses

The following table identifies the Bus Masters and their access to the various memories on the bus matrix.

Table 8-5. Master Memory Access Availability

Master	Flash Access	ROM Access	SRAM Access	EEPROM Access	External Memory Access (via EPI)
CPU Instruction Bus	Yes	Yes (read-only)	Yes	Yes	Yes
CPU Data Bus	Yes	Yes (read-only)	-	Yes	Yes
μDMA	Yes (read-only, Run-Mode-only)	-	Yes	Yes	Yes
Ethernet Module	-	-	Yes	-	-
USB	-	-	Yes	-	-
LCD	-	-	Yes	-	Yes

8.3 Register Map

Table 8-6 on page 651 lists the ROM Controller register and the Flash memory control registers. The offset listed is a hexadecimal increment to the register's address. The Flash memory register offsets are relative to the Flash memory control base address of 0x400F.D000. The EEPROM registers are relative to the EEPROM base address of 0x400A.F000. The ROM control and Flash memory protection register offsets are relative to the System Control base address of 0x400F.E000.

Table 8-6. Flash Register Map

8.4 Internal Memory Register Descriptions (Internal Memory Control Offset)

This section lists and describes the memory control registers, in numerical order by address offset. Registers in this section are relative to the memory control base address of 0x400F.D000.

Register 1: Flash Memory Address (FMA), offset 0x000

During a write operation, this register contains a 4-byte-aligned address and specifies where the data is written. During erase operations for flash space that is not user configurable (that is, **FMPREn**, **FMPPEn**, **USER_REGn**, **BOOTCFG**), this register contains a 16 KB-aligned CPU byte address and specifies which block is erased. Note that the alignment requirements must be met by software or the results of the operation are unpredictable.

Flash Memory Address (FMA)

Base 0x400F.D000

Offset 0x000

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:19	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
18:0	OFFSET	RW	0x0	Address Offset Address offset in Flash memory where operation is performed, except for non-volatile registers (see “Non-Volatile Register Programming--Flash Memory Resident Registers” on page 643 for details on values for this field).

Register 2: Flash Memory Data (FMD), offset 0x004

This register contains the data to be written during the programming cycle. Note that the contents of this register are undefined for a read access of an execute-only block. This register is not used during erase cycles.

Flash Memory Data (FMD)

Base 0x400F.D000
Offset 0x004
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	DATA	RW	0x0000.0000	Data Value Data value for write operation.

Register 3: Flash Memory Control (FMC), offset 0x008

When this register is written, the Flash memory controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 653). If the access is a write access, the data contained in the **Flash Memory Data (FMD)** register (see page 654) is written to the specified address.

For non-volatile registers, **FMPREn**, **FMPPEn**, **USER_REGn**, and **USER_REGn**, the respective register is programmed with the value to be written rather than the **FMD** register.

This register must be the final register written and initiates the memory operation. The four control bits in the lower byte of this register are used to initiate memory operations.

Care must be taken not to set multiple control bits as the results of such an operation are unpredictable.

Flash Memory Control (FMC)

Base 0x400F.D000
Offset 0x008
Type RW, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WRKEY															
Type	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RW	RW	RW	RW
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	WRKEY	WO	0x0000	Flash Memory Write Key This field contains a write key, which is used to minimize the incidence of accidental Flash memory writes. The value 0xA442 or the PEKEY value in the FLPEKEY register must be written into this field for a Flash memory write to occur. The use of 0xA442 or PEKEY is dependent on the value of the KEY bit in the BOOTCFG register at 0x1D0. Writes to the FMC register without this WRKEY value are ignored. A read of this field returns the value 0.
15:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description						
3	COMT	RW	0	<p>Commit Register Value</p> <p>This bit is used to commit writes to Flash-memory-resident registers and to monitor the progress of that process.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>A write of 0 has no effect on the state of this bit. When read, a 0 indicates that the previous commit access is complete.</td></tr> <tr> <td>1</td><td>Set this bit to commit (write) the register value to a Flash-memory-resident register. Value	Description									
0	A write of 0 has no effect on the state of this bit. When read, a 0 indicates that the previous page erase access is complete.									
1	Set this bit to erase the Flash memory page specified by the contents of the FMA register. When read, a 1 indicates that the previous page erase access is not complete.									

Bit/Field	Name	Type	Reset	Description
0	WRITE	RW	0	<p>Write a Word into Flash Memory</p> <p>This bit is used to write a word into Flash memory and to monitor the progress of that process.</p>
Value Description				
<p>0 A write of 0 has no effect on the state of this bit. When read, a 0 indicates that the previous write update access is complete.</p>				
<p>1 Set this bit to write the data stored in the FMD register into the Flash memory location specified by the contents of the FMA register. When read, a 1 indicates that the write update access is not complete.</p>				

For information on programming time, see "Flash Memory" on page 2122.

Register 4: Flash Controller Raw Interrupt Status (FCRIS), offset 0x00C

This register indicates that the Flash memory controller has an interrupt condition. An interrupt is sent to the interrupt controller only if the corresponding **FCIM** register bit is set.

Flash Controller Raw Interrupt Status (FCRIS)

Base 0x400F.D000
Offset 0x00C
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:14	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13	PROGRIS	RO	0	Program Verify Error Raw Interrupt Status
	Value Description			
	0	An interrupt has not occurred.		
	1	An interrupt is pending because the verify of a PROGRAM operation failed. If this error occurs when using the Flash write buffer, software must inspect the affected words to determine where the error occurred.		
				This bit is cleared by writing a 1 to the PROGMISC bit in the FCMISC register.
12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	ERRIS	RO	0	Erase Verify Error Raw Interrupt Status
	Value Description			
	0	An interrupt has not occurred.		
	1	An interrupt is pending because the verify of an ERASE operation failed. If this error occurs when using the Flash write buffer, software must inspect the affected words to determine where the error occurred.		
				This bit is cleared by writing a 1 to the ERMISC bit in the FCMISC register.

A write of 0 has no effect on the state of this bit.	1	When read, a 1 indicates that an unmasked interrupt was signaled because a program or erase action was attempted on a block of Flash memory that contradicts the protection policy for that block as set in the FMPPEn registers. Writing a 1 to this bit clears AMISC and also the ARIS bit in the FCRIS register (see page 658).
Value	Description									
0	When read, a 0 indicates that no improper accesses have occurred. A write of 0 has no effect on the state of this bit.									
1	When read, a 1 indicates that an unmasked interrupt was signaled because a program or erase action was attempted on a block of Flash memory that contradicts the protection policy for that block as set in the FMPPEn registers. Writing a 1 to this bit clears AMISC and also the ARIS bit in the FCRIS register (see page 658).									

Register 7: Flash Memory Control 2 (FMC2), offset 0x020

When this register is written, the Flash memory controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 653). If the access is a write access, the data contained in the **Flash Write Buffer (FWB)** registers is written.

This register must be the final register written as it initiates the memory operation.

Flash Memory Control 2 (FMC2)

Base 0x400F.D000
Offset 0x020
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:16	WRKEY	WO	0x0000	<p>Flash Memory Write Key</p> <p>This field contains a write key, which is used to minimize the incidence of accidental Flash memory writes. There are two options for the WRKEY value:</p> <ul style="list-style-type: none"> If the KEY value in the BOOTCFG register is 0x1 at reset, the value 0xA442 is used as a key enable to initiate the appropriate access cycle for the location specified by the address in the FMA register. If the KEY value in the BOOTCFG register is 0x0 at reset, the value programmed in the FLPEKEY register is used as a key enable to initiate the appropriate access cycle for the location specified by the address in the FMA register. <p>Writes to the FMC2 register without this WRKEY value are ignored. A read of this field returns the value 0.</p>						
15:1	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Value	Description									
0	<p>A write of 0 has no effect on the state of this bit.</p> <p>When read, a 0 indicates that the previous buffered Flash memory write access is complete.</p>									
1	<p>Set this bit to write the data stored in the FWBn registers to the location specified by the contents of the FMA register.</p> <p>When read, a 1 indicates that the previous buffered Flash memory write access is not complete.</p>									

For information on programming time, see "Flash Memory" on page 2122.

Register 8: Flash Write Buffer Valid (FWBVAL), offset 0x030

This register provides a bitwise status of which **FWBn** registers have been written by the processor since the last write of the Flash memory write buffer. The entries with a 1 are written on the next write of the Flash memory write buffer. This register is cleared after the write operation by hardware. A protection violation on the write operation also clears this status.

Software can program the same 32 words to various Flash memory locations by setting the FWB[n] bits after they are cleared by the write operation. The next write operation then uses the same data as the previous one. In addition, if a **FWBn** register change should not be written to Flash memory, software can clear the corresponding FWB[n] bit to preserve the existing data when the next write operation occurs.

Flash Write Buffer Valid (FWBVAL)

Base 0x400F.D000

Offset 0x030

Bit/Field	Name	Type	Reset	Description
31:0	FWB[n]	RW	0x0	Flash Memory Write Buffer
				Value Description
				0 The corresponding FWBn register has no new data to be written.
				1 The corresponding FWBn register has been updated since the last buffer write operation and is ready to be written to Flash memory.

Bit 0 corresponds to **FWB0**, offset 0x100, and bit 31 corresponds to **FWB31**, offset 0x13C.

Register 9: Flash Program/Erase Key (FLPEKEY), offset 0x03C

This register provides a mechanism for protection from inadvertent writes to flash by supplying a 16-bit key . If the KEY value in the **BOOTCFG** register is 0, then this value is used as the 16-bit key in place of 0xA442 in the **FMC/FMC2** registers for committed flash writes.

This can be used for cases where a new image is downloaded and the first word of the new image has the 16-bit key value to be used for that product. This 16-bit key is used to allow the write to **FMC** or **FMC2** to take place.

Flash Program/Erase Key (FLPEKEY)

Base 0x400F.D000
Offset 0x03C
Type RO, reset 0x0000.FFFF

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	PEKEY	RO	0xFFFF	Key Value When a value other than all 1s or all 0s, this 16-bit value is used as the "match" for the upper 16-bits of the register FMC and FMC2 keys.

Register 10: Flash Write Buffer n (FWBn), offset 0x100 - 0x17C

These 32 registers hold the contents of the data to be written into the Flash memory on a buffered Flash memory write operation. The offset selects one of the 32-bit registers. Only **FWBn** registers that have been updated since the preceding buffered Flash memory write operation are written into the Flash memory, so it is not necessary to write the entire bank of registers in order to write 1 or 2 words. The **FWBn** registers are written into the Flash memory with the **FWB0** register corresponding to the address contained in **FMA**. **FWB1** is written to the address **FMA+0x4** etc. Note that only data bits that are 0 result in the Flash memory being modified. A data bit that is 1 leaves the content of the Flash memory bit at its previous value.

8.5 EEPROM Register Descriptions (EEPROM Offset)

This section lists and describes the EEPROM registers, in numerical order by address offset. Registers in this section are relative to the EEPROM base address of 0x400A.F000.

Note that the EEPROM module clock must be enabled before the registers can be programmed (see page 416). There must be a delay of 3 system clocks after the EEPROM module clock is enabled before any EEPROM module registers are accessed. In addition, after enabling or resetting the EEPROM module, software must wait until the WORKING bit in the **EEDONE** register is clear before accessing any EEPROM registers.

Register 17: EEPROM Size Information (EESIZE), offset 0x000

The **EESIZE** register indicates the number of 16-word blocks and 32-bit words in the EEPROM.

EEPROM Size Information (EESIZE)

Base 0x400A.F000
Offset 0x000
Type RO, reset 0x0060.0600

Bit/Field	Name	Type	Reset	Description
31:27	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
26:16	BLKCNT	RO	0x60	Number of 16-Word Blocks This value encoded in this field describes the number of 16-word blocks in the EEPROM.
15:0	WORDCNT	RO	0x600	Number of 32-Bit Words This value encoded in this field describes the number of 32-bit words in the EEPROM.

Register 18: EEPROM Current Block (EEBLOCK), offset 0x004

The **EEBLOCK** register is used to select the EEPROM block for subsequent reads, writes, and protection control. The value is a page offset into the EEPROM, such that the first block is 0, then second block is 1, etc. Each block contains 16 words. Attempts to set an invalid block causes the **BLOCK** field to be configured to 0. To verify that the intended block is being accessed, software can read the **BLOCK** field after it has been written. An invalid block can be either a non-existent block or a block that has been hidden using the **EEHIDE** register. Note that block 0 cannot be hidden.

EEPROM Current Block (EEBLOCK)

Base 0x400A.F000

Offset 0x004

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	BLOCK	RW	0x0000	<p>Current Block</p> <p>This field specifies the block in the EEPROM that is selected for subsequent accesses. Once this field is configured, the read-write registers operate against the specified block, using the EEOFFSET register to select the word within the block. Additionally, the protection and unlock registers are used for the selected block. The maximum value that can be written into this register is determined by the block count, as indicated by the EESIZE register. Attempts to write this field larger than the maximum number of blocks or to a locked block causes this field to be configured to 0.</p>

Register 19: EEPROM Current Offset (EEOFFSET), offset 0x008

The **EEOFFSET** register is used to select the EEPROM word to read or write within the block selected by the **EEBLOCK** register. The value is a word offset into the block. Because accesses to the **EERDWRINC** register change the offset, software can read the contents of this register to determine the current offset.

EEPROM Current Offset (EEOFFSET)

Base 0x400A.F000
Offset 0x008
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	OFFSET	RW	0x0	<p>Current Address Offset</p> <p>This value is the current address specified as an offset into the block selected by the EEBLOCK register. Once configured, the read-write registers, EERDRWR and EERDWRINC, operate against that address. The offset is automatically incremented by the EERDWRINC register, with wrap around within the block, which means the offset is incremented from 15 back to 0.</p>

Register 20: EEPROM Read-Write (EERDWR), offset 0x010

The **EERDWR** register is used to read or write the EEPROM word at the address pointed to by the **EEBLOCK** and **EEOFFSET** registers. If the protection or access rules do not permit access, the operation is handled as follows: if reading is not allowed, the value 0xFFFF.FFFF is returned in all cases; if writing is not allowed, the **EEDONE** register is configured to indicate an error.

Note: A read of the **EERDWR** register during the EEPROM initialization sequence is only valid when the WORKING bit is 0 in **EEDONE** register:

EEPROM Read-Write (EERDWR)

Base 0x400A.F000
Offset 0x010
Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:0	VALUE	RW	-	EEPROM Read or Write Data On a read, this field contains the value at the word pointed to by EEOFFSET . On a write, this field contains the data to be stored at the word pointed to by EEOFFSET . For writes, configuring this field starts the write process. If protection and access rules do not permit reads, all 1s are returned. If protection and access rules do not permit writes, the write fails and the EEDONE register indicates failure.

Register 21: EEPROM Read-Write with Increment (EERDWRINC), offset 0x014

The **EERDWRINC** register is used to read or write the EEPROM word at the address pointed to by the **EEBLOCK** and **EEOFFSET** registers, and then increment the **OFFSET** field in the **EEOFFSET** register. If the protection or access rules do not permit access, the operation is handled as follows: if reading is not allowed, the value 0xFFFF.FFFF is returned in all cases; if writing is not allowed, the **EEDONE** register is configured to indicate an error. In any case, the **OFFSET** field is incremented. If the last value is reached, **OFFSET** wraps around to 0 and points to the first word.

Note: A read of the **EERDWRINC** register during the EEPROM initialization sequence is only valid when the **WORKING** bit is 0 in **EEDONE** register:

EEPROM Read-Write with Increment (EERDWRINC)

Base 0x400A.F000

Offset 0x014

Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:0	VALUE	RW	-	<p>EEPROM Read or Write Data with Increment</p> <p>On a read, this field contains the value at the word pointed to by EEOFFSET. On a write, this field contains the data to be stored at the word pointed to by EEOFFSET. For writes, configuring this field starts the write process. If protection and access rules do not permit reads, all 1s are returned. If protection and access rules do not permit writes, the write fails and the EEDONE register indicates failure.</p> <p>Regardless of error, the OFFSET field in the EEOFFSET register is incremented by 1, and the value wraps around if the last word is reached.</p>

Register 22: EEPROM Done Status (EEDONE), offset 0x018

The **EEDONE** register indicates completion status of a write to the following registers:

- **EERDWR** or **EERDWRINC** register (for writes to the EEPROM memory)
- **EEPROT** register (for setting read and protection of the current block)
- **EEPASSn** registers (for configuring a password for a block)
- **EEDBGME** register (for mass erase of an EEPROM block)

This register can indicate if the write ended in an error or not. The **EEDONE** register can be used in conjunction with the **EEINT** register to be indicate completion. The register can be **EEDONE** polled or read after an **EEINT** register interrupt fires. If any of the bit values in the **EEDONE** register are 1 after completion, then an error has occurred for that register write. If all of the bits are clear then the writes completed with success.

Note: Reads of the following registers during the EEPROM initialization sequence are only valid when the **WORKING** bit is 0 in **EEDONE** register:

- **EERDWR** or **EERDWRINC**
- **EEPROT**
- **EEPASSn**

1	The EEPROM is performing the requested operation.									

Register 23: EEPROM Support Control and Status (EESUPP), offset 0x01C

The **EESUPP** register indicates if internal operations are required because an internal copy buffer must be erased or a programming failure has occurred and the operation must be completed. These conditions are explained below as well as in more detail in the section called “Error During Programming” on page 648.

- If either PRETRY or ERETRY is set indicating that an operation must be completed, setting the START bit causes the operation to be performed again
- The PRETRY and ERETRY bits are cleared automatically after the failed operation has been successfully completed.

These bits are not changed by reset, so any condition that occurred before a reset is still indicated after a reset.

EEPROM Support Control and Status (EESUPP)

Base 0x400A.F000

Offset 0x01C

Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	PRETRY	RO	-	Programming Must Be Retried
		Value	Description	
		0	Programming has not failed.	
		1	Programming from a copy in either direction failed to complete.	
2	ERETRY	RO	-	Erase Must Be Retried
		Value	Description	
		0	Erasing has not failed.	
		1	Erasing failed to complete. If the failed erase is due to the erase of a main buffer, the copy is performed after the erase completes successfully.	
1:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 24: EEPROM Unlock (EEUNLOCK), offset 0x020

The **EEUNLOCK** register can be used to unlock the whole EEPROM or a single block using a password. Unlocking is only required if a password is registered using the **EPPASSn** registers for the block that is selected by the **EEBLOCK** register. If block 0 has a password, it locks the remaining blocks from any type of access, but uses its own protection mechanism, for example readable, but not writable when locked. In addition, if block 0 has a password, it must be unlocked before unlocking any other block.

The **EEUNLOCK** register is written between 1 and 3 times to form the 32-bit, 64-bit, or 96-bit password registered using the **EPPASSn** registers. The value used to configure the **EPPASS0** register must always be written last. For example, for a 96-bit password, the value used to configure the **EPPASS2** register must be written first followed by the **EPPASS1** and **EPPASS0** register values. The block or the whole EEPROM can be re-locked by writing 0xFFFF.FFFF to this register.

In the event that an invalid value is written to this register, the block remains locked. The state of the EEPROM lock can be determined by reading back the **EEUNLOCK** register. If a multi-word password is set and the number of words written is incorrect, writing 0xFFFF.FFFF to this register reverts the EEPROM lock to the locked state, and the proper unlock sequence can be retried.

Note that the internal logic is balanced to prevent any electrical or time-based attack being used to find the correct password or its length.

Note: A read of the **EEUNLOCK** register during the EEPROM initialization sequence is only valid when the **WORKING** bit is 0 in **EEDONE** register:

EEPROM Unlock (EEUNLOCK)

Base 0x400A.F000

Offset 0x020

Type RW, reset -

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	UNLOCK	RW	-	EEPROM Unlock
------	--------	----	---	---------------

Value Description

0	The EEPROM is locked.
---	-----------------------

1	The EEPROM is unlocked.
---	-------------------------

The EEPROM is locked if the block referenced by the **EEBLOCK** register has a password registered, or if the master block (block 0) has a password. Unlocking is performed by writing the password to this register. The block or the EEPROM stays unlocked until it is locked again or until the next reset. It can be locked again by writing 0xFFFF.FFFF to this register.

Register 25: EEPROM Protection (EEPROT), offset 0x030

The **EEPROT** register is used to set or read the protection for the current block, as selected by the **EBLOCK** register. Protection and access control is used to determine when a block's contents can be read or written.

Note: A read of the **EEPROT** register during the EEPROM initialization sequence is only valid when the WORKING bit is 0 in **EEDONE** register:

EEPROM Protection (EEPROT)

Base 0x400A.F000
Offset 0x030
Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:4 reserved RO 0x0000.0000 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

3 ACC RW 0 Access Control

Value Description

0 Both user and supervisor code may access this block of the EEPROM.

1 Only supervisor code may access this block of the EEPROM. μ DMA and Debug are also prevented from accessing the EEPROM.

If this bit is set for block 0, then the whole EEPROM may only be accessed by supervisor code.

Bit/Field	Name	Type	Reset	Description
2:0	PROT	RW	0x0	Protection Control The Protection bits control what context is needed for reading and writing the block selected by the EEBLOCK register, or if block 0 is selected, all blocks. The following values are allowed:
Value Description				
0x0 This setting is the default. Without password: the block is not protected and is readable and writable at any time. With password: the block is readable, but only writable when unlocked.				
0x1 With password: the block is readable or writable only when unlocked. This value has no meaning when there is no password.				
0x2 Without password: the block is readable, not writable. With password: the block is readable only when unlocked, but is not writable under any conditions.				
0x3 Reserved				

Register 26: EEPROM Password (EEPASS0), offset 0x034**Register 27: EEPROM Password (EEPASS1), offset 0x038****Register 28: EEPROM Password (EEPASS2), offset 0x03C**

The **EEPASSn** registers are used to configure a password for a block. A password may only be set once and cannot be changed. The password may be 32-bits, 64-bits, or 96-bits. Each word of the password can be any 32-bit value other than 0xFFFF.FFFF (all 1s). To set a password, the **EEPASS0** register is written to with a value other than 0xFFFF.FFFF. When the write completes, as indicated in the **EEDONE** register, the application may choose to write to the **EEPASS1** register with a value other than 0xFFFF.FFFF. When that write completes, the application may choose to write to the **EEPASS2** register with a value other than 0xFFFF.FFFF to create a 96-bit password. The registers do not have to be written consecutively, and the **EEPASS1** and **EEPASS2** registers may be written at a later date. Based on whether 1, 2, or all 3 registers have been written, the unlock code also requires the same number of words to unlock.

Note: Once the password is written, the block is not actually locked until either a reset occurs or 0xFFFF.FFFF is written to **EEUNLOCK**.

Note: A read of the **EEPASSn** register during the EEPROM initialization sequence is only valid when the **WORKING** bit is 0 in **EEDONE** register:

EEPROM Password (EEPASSn)

Reset	-	RW														

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	PASS	RW	-	Password
------	------	----	---	----------

This register reads as 0x1 if a password is registered for this block and 0x0 if no password is registered. A write to this register if it reads as 0x0 sets the password. If an attempt is made to write to this register when it reads as 0x1, the write is ignored and the **NOPERM** bit in the **EEDONE** register is set.

Register 29: EEPROM Interrupt (EEINT), offset 0x040

The **EEINT** register is used to control whether an interrupt should be generated when a write to EEPROM completes as indicated by the **EEDONE** register value changing from 0x1 to any other value. If the **INT** bit in this register is set, the **ERIS** bit in the **Flash Controller Raw Interrupt Status (FCRIS)** register is set whenever the **EEDONE** register value changes from 0x1 as the Flash memory and the EEPROM share an interrupt vector.

0	INT	RW	0	Interrupt Enable
		Value	Description	
		0	No interrupt is generated.	
		1	An interrupt is generated when the EEDONE register transitions from 1 to 0 or an error occurs. The EEDONE register provides status after a write to an offset location as well as a write to the password and protection bits.	

Register 30: EEPROM Block Hide 0 (EEHIDE0), offset 0x050

The **EEHIDE0** register is used to hide one or more blocks other than EEPROM block 0. Bits 1 through 31 of this register correspond to EEPROM blocks 1 through 31. Once hidden, the block is not accessible until the next reset. This model allows initialization code to have access to data which is not visible to the rest of the application. This register also provides for additional security in that there is no password to search for in the code or data.

EEPROM Block Hide 0 (EEHIDE0)

Base 0x400A.F000

Offset 0x050

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	Hn	RW	0x0000.0000	<p>Value Description</p> <p>0 The corresponding block is not hidden.</p> <p>1 The block number that corresponds to the bit number is hidden. A hidden block cannot be accessed, and the OFFSET value in the EEBLOCK register cannot be set to that block number. If an attempt is made to configure the OFFSET field to a hidden block, the EEBLOCK register is cleared.</p> <p>Any attempt to clear a bit in this register that is set is ignored.</p>
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 31: EEPROM Block Hide 1 (EEHIDE1), offset 0x054**Register 32: EEPROM Block Hide 2 (EEHIDE2), offset 0x058**

The **EEHIDE** register is used to hide one or more blocks. Bits 0 through 31 of the EEHIDE1 register correspond to EEPROM blocks 32 through 63. Bits 0 through 31 of the EEHIDE2 register correspond to EEPROM blocks 64 through 95. Once hidden, the block is not accessible until the next reset. This model allows initialization code to have access to data which is not visible to the rest of the application. This register also provides for additional security in that there is no password to search for in the code or data.

EEPROM Block Hide n (EEHIDEn)

Base 0x400A.F000

Offset 0x054

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	Hn	RW	0x0000.0000	Hide Block

Value Description

0 The corresponding block is not hidden.

1 The block number that corresponds to the bit number is hidden. A hidden block cannot be accessed, and the **OFFSET** value in the **EEBLOCK** register cannot be set to that block number. If an attempt is made to configure the **OFFSET** field to a hidden block, the **EEBLOCK** register is cleared.

Any attempt to clear a bit in this register that is set is ignored.

Register 33: EEPROM Debug Mass Erase (EEDBGME), offset 0x080

The **EEDBGME** register is used to mass erase the EEPROM block back to its default state from the factory. This register is intended to be used only for debug and test purposes, not in production environments. The erase takes place in such a way as to be secure. It first erases all data and then erases the protection mechanism. This register can only be written from supervisor mode by the core, and can also be written by the Tiva™ C Series debug controller when enabled. A key is used to avoid accidental use of this mechanism. Note that if a power down takes place while erasing, the mechanism should be used again to complete the operation. Powering off prematurely does not expose secured data.

To start a mass erase, the whole register must be written as 0xE37B.0001. The register reads back as 0x1 until the erase is fully completed at which time it reads as 0x0. The **EEDONE** register is set to 0x1 when the erase is started and changes to 0x0 or an error when the mass erase is complete.

EEPROM Debug Mass Erase (EEDBGME)

Base 0x400A.F000

15:0	SIZE	RO	0x1FF	EEPROM Size Indicates the size of the on-chip EEPROM. Any values not shown are reserved. Value Description 0x0000 64 bytes of EEPROM 0x0001 128 bytes of EEPROM 0x0003 256 bytes of EEPROM 0x0007 512 bytes of EEPROM 0x000F 1 KB of EEPROM 0x001F 2 KB of EEPROM 0x003F 3 KB of EEPROM 0x007F 4 KB of EEPROM 0x00FF 5 KB of EEPROM 0x01FF 6 KB of EEPROM

8.6 Memory Register Descriptions (System Control Offset)

The remainder of this section lists and describes the registers that reside in the System Control address space, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

Register 35: Reset Vector Pointer (RVP), offset 0x0D4

The **Reset Vector Pointer (RVP)** register contains the address of the reset vector of the software module that is to be executed after boot loader execution. The **RVP** register is initialized by a power-on reset.

Reset Vector Pointer (RVP)

Base 0x400F.E000
Offset 0x0D4
Type RO, reset 0x0101.FFF0

Bit/Field	Name	Type	Reset	Description
31:0	RV	RO	0x0101.FFF0	Reset Vector Pointer Address

Register 36: Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x200

Register 37: Flash Memory Protection Read Enable 1 (FMPRE1), offset 0x204

Register 38: Flash Memory Protection Read Enable 2 (FMPRE2), offset 0x208

Register 39: Flash Memory Protection Read Enable 3 (FMPRE3), offset 0x20C

Register 40: Flash Memory Protection Read Enable 4 (FMPRE4), offset 0x210

Register 41: Flash Memory Protection Read Enable 5 (FMPRE5), offset 0x214

Register 42: Flash Memory Protection Read Enable 6 (FMPRE6), offset 0x218

Register 43: Flash Memory Protection Read Enable 7 (FMPRE7), offset 0x21C

Note: The **FMPRE0** register is aliased for backwards compatibility.

Note: Offset is relative to System Control base address of 0x400F.E000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). Note that for protecting sectors, eight bits need to be cleared to create a 16-KB read-protected sector.

This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is RW0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter.

Each **FMPREn** register controls a 64K block. For additional information, see "Protected Flash Memory Registers" on page 639.

- **FMPRE0:** 0 to 64 KB
- **FMPRE1:** 65 to 128 KB
- **FMPRE2:** 129 to 192 KB
- **FMPRE3:** 193 to 256 KB
- **FMPRE4:** 257 to 320 KB
- **FMPRE5:** 321 to 384 KB
- **FMPRE6:** 385 to 448 KB
- **FMPRE7:** 449 to 512 KB

Flash Memory Protection Read Enable n (FMPREn)

Base 0x400F.E000
 Offset 0x200
 Type RW, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	RW	0xFFFF.FFFF	<p>Flash Read Enable</p> <p>Each bit configures a 2-KB flash block to be read only. Note that for read-protection of sectors, eight bits need to be cleared to create a 16-KB read-protected sector.</p> <p>The policies may be combined as shown in the table "Flash Protection Policy Combinations".</p>

Register 44: Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x400

Register 45: Flash Memory Protection Program Enable 1 (FMPPE1), offset 0x404

Register 46: Flash Memory Protection Program Enable 2 (FMPPE2), offset 0x408

Register 47: Flash Memory Protection Program Enable 3 (FMPPE3), offset 0x40C

Register 48: Flash Memory Protection Program Enable 4 (FMPPE4), offset 0x410

Register 49: Flash Memory Protection Program Enable 5 (FMPPE5), offset 0x414

Register 50: Flash Memory Protection Program Enable 6 (FMPPE6), offset 0x418

Register 51: Flash Memory Protection Program Enable 7 (FMPPE7), offset 0x41C

Note: The **FMPPE0** register is aliased for backwards compatibility.

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the read-only protection bits). Since the memory is two-way interleaved and each bank individually is an 8-KB sector, read-only protection must occur across a block size of 16-KB. No smaller block size is supported. Note that the **Flash Memory Protection Read (FMPREn)** registers do allow read-protection of a block as small as 2 KB, unlike the **FMPPEn** registers.

Thus, in order to execute-only protect a 16-KB block, a user must program the entire eight bits of the byte to the same value. For example, to protect the first 16-KB block, bits [7:0] of the **FMPPE0** register need to be cleared to all 0s.

This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. This register is RW0; the user can only change the protection byte from all 1s to all 0s (and may NOT change from all 0 to all 1). The changes are not permanent until the register is committed (saved), at which point the byte change is permanent. If a byte is changed from all 1s to all 0s and not committed, it may be restored by executing a power-on reset sequence. The reset value shown only applies to power-on reset; any other type of reset does not affect this register. Once committed, the only way to restore the factory default value of this register is to perform the "Recover Locked Device" sequence detailed in the JTAG chapter. For additional information, see "Protected Flash Memory Registers" on page 639.

Each **FMPPEn** register controls a 64K block. For additional information, see "Protected Flash Memory Registers" on page 639.

- **FMPPE0:** 0 to 64 KB
- **FMPPE1:** 65 to 128 KB
- **FMPPE2:** 129 to 192 KB
- **FMPPE3:** 193 to 256 KB

- **FMPPE4:** 257 to 320 KB
- **FMPPE5:** 321 to 384 KB
- **FMPPE6:** 385 to 448 KB
- **FMPPE7:** 449 to 512 KB

Flash Memory Protection Program Enable n (FMPPEn)

Base 0x400F.E000

Offset 0x400

Type RW, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	PROG_ENABLE	RW	0xFFFF.FFFF	Flash Programming Enable Every eighth bit programs an 16-KB flash sector to be execute only. The policies may be combined as shown in Table 8-2 on page 640.

Register 52: Boot Configuration (BOOTCFG), offset 0x1D0

Note: Offset is relative to System Control base address of 0x400F.E000.

Note: The **Boot Configuration (BOOTCFG)** register requires a POR before the committed changes take effect.

This register is not written directly, but instead uses the **FMD** register as explained in “Non-Volatile Register Programming-- Flash Memory Resident Registers” on page 643. When this register is committed, the new value cannot be read back until after the power cycle. This register provides configuration of a GPIO pin to enable the ROM Boot Loader as well as a write-once mechanism to disable external debugger access to the device. At reset, the user has the opportunity to direct the core to execute the ROM Boot Loader or the application in Flash memory by using any GPIO signal from Ports A through H as configured by the bits in this register. At reset, the following sequence is performed:

1. The **BOOTCFG** register is read. If the **EN** bit is clear, the ROM Boot Loader is executed.
2. In the ROM Boot Loader, the status of the specified GPIO pin is compared with the specified polarity. If the status matches the specified polarity, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
3. If the **EN** bit is set or the status doesn't match the specified polarity, the data at address 0x0000.0004 is read, and if the data at this address is 0xFFFF.FFFF, the ROM is mapped to address 0x0000.0000 and execution continues out of the ROM Boot Loader.
4. If there is data at address 0x0000.0004 that is not 0xFFFF.FFFF, the stack pointer (**SP**) is loaded from Flash memory at address 0x0000.0000 and the program counter (**PC**) is loaded from address 0x0000.0004. The user application begins executing.

The **DBG0** bit is cleared by the factory and the **DBG1** bit is set, which enables external debuggers. Clearing the **DBG1** bit disables any external debugger access to the device, starting with the next power-up cycle of the device. The **NW** bit indicates that bits in the register can be changed from 1 to 0.

By committing the register values using the **COMT** bit in the **FMC** register, the register contents become non-volatile and are therefore retained following power cycling. Prior to being committed, bits can only be changed from 1 to 0. The reset value shown only applies to power-on reset when the register is not yet committed; any other type of reset does not affect this register. Once committed, the register retains its value through power-on reset. Once committed, the only way to restore the factory default value of this register is to perform the sequence detailed in “Recovering a “Locked” Microcontroller” on page 223.

9 Micro Direct Memory Access (μDMA)

The TM4C129XKCZAD microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA (μDMA). The μDMA controller provides a way to offload data transfer tasks from the Cortex™-M4F processor, allowing for more efficient use of the processor and the available bus bandwidth. The μDMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The μDMA controller provides the following features:

- ARM® PrimeCell® 32-channel configurable μDMA controller
- Support for memory-to-memory, memory-to-peripheral, and peripheral-to-memory in multiple transfer modes
 - Basic for simple transfer scenarios
 - Ping-pong for continuous data flow
 - Scatter-gather for a programmable list of up to 256 arbitrary transfers initiated from a single request
- Highly flexible and configurable channel operation
 - Independently configured and operated channels
 - Dedicated channels for supported on-chip modules
 - Flexible channel assignments
 - One channel each for receive and transmit path for bidirectional modules
 - Dedicated channel for software-initiated transfers
 - Per-channel configurable priority scheme
 - Optional software-initiated requests for any channel
- Two levels of priority
- Design optimizations for improved bus access performance between μDMA controller and the processor core
 - μDMA controller access is subordinate to core access
 - RAM striping
 - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Transfer size is programmable in binary steps from 1 to 1024
- Source and destination address increment size of byte, half-word, word, or no increment

- Maskable peripheral requests
- Interrupt on transfer completion, with a separate interrupt per channel

9.1 Block Diagram

Figure 9-1. μ DMA Block Diagram

9.2 Functional Description

The μ DMA controller is a flexible and highly configurable DMA controller designed to work efficiently with the microcontroller's Cortex-M4F processor core. It supports multiple data sizes and address increment schemes, multiple levels of priority among DMA channels, and several transfer modes to allow for sophisticated programmed data transfers. The μ DMA controller's usage of the bus is always subordinate to the processor core, so it never holds up a bus transaction by the processor. Because the μ DMA controller is only using otherwise-idle bus cycles, the data transfer bandwidth it provides is essentially free, with no impact on the rest of the system. The bus architecture has been optimized to greatly enhance the ability of the processor core and the μ DMA controller to efficiently share the on-chip bus, thus improving performance. The optimizations include RAM striping and peripheral bus segmentation, which in many cases allow both the processor core and the μ DMA controller to access the bus and perform simultaneous data transfers.

Each peripheral function that is supported has a dedicated channel on the μ DMA controller that can be configured independently. The μ DMA controller implements a unique configuration method using channel control structures that are maintained in system memory by the processor. While simple transfer modes are supported, it is also possible to build up sophisticated "task" lists in memory that allow the μ DMA controller to perform arbitrary-sized transfers to and from arbitrary locations as part of a single transfer request. The μ DMA controller also supports the use of ping-pong buffering to accommodate constant streaming of data to or from a peripheral.

Each channel also has a configurable arbitration size. The arbitration size is the number of items that are transferred in a burst before the μ DMA controller re-arbitrates for channel priority. Using

the arbitration size, it is possible to control exactly how many items are transferred to or from a peripheral each time it makes a µDMA service request.

9.2.1 Channel Assignments

Each DMA channel has up to nine possible assignments which are selected using the **DMA Channel Map Select n (DMACHMAPn)** registers with 4-bit assignment fields for each µDMA channel.

Table 9-1 on page 707 shows the µDMA channel mapping. The Enc. column shows the encoding for the respective **DMACHMAPn** bit field. Encodings 0x9-0xF are reserved. To support legacy software which uses the **DMA Channel Assignment (DMACHASGN)** register, Enc. 0 is equivalent to a **DMACHASGN** bit being clear, and Enc. 1 is equivalent to a **DMACHASGN** bit being set. If the **DMACHASGN** register is read, bit fields return 0 if the corresponding **DMACHMAPn** register field value are equal to 0, otherwise they return 1 if the corresponding **DMACHMAPn** register field values are not equal to 0. The Type indication in the table indicates if a particular peripheral uses a single request (S), burst request (B) or either (SB).

Note: Channels or encodings marked as reserved cannot be used for µDMA transfers. Channels designated in the table as only "Software" are dedicated software channels. When only one software request is required in an application, dedicated software channels can be used. If multiple software requests in code are required, then peripheral channel software requests should be used for proper µDMA completion acknowledgement.

Table 9-1. µDMA Channel Assignments

9.2.2 Priority

The μ DMA controller assigns priority to each channel based on the channel number and the priority level bit for the channel. Channel number 0 has the highest priority and as the channel number increases, the priority of a channel decreases. Each channel has a priority level bit to provide two

levels of priority: default priority and high priority. If the priority level bit is set, then that channel has higher priority than all other channels at default priority. If multiple channels are set for high priority, then the channel number is used to determine relative priority among all the high priority channels.

The priority bit for a channel can be set using the **DMA Channel Priority Set (DMAPRIOSET)** register and cleared with the **DMA Channel Priority Clear (DMAPRIOCLR)** register.

Note: If one peripheral is mapped to two different channels, then the application should either use the default mapping for that peripheral or change the default mapping to another source. For example, if UART1 channels 8 and 9 are enabled for use, then even if channels 22 and 23 are disabled, they must be mapped to software or another peripheral (if available).

9.2.3 Arbitration Size

When a μDMA channel requests a transfer, the μDMA controller arbitrates among all the channels making a request and services the μDMA channel with the highest priority. Once a transfer begins, it continues for a selectable number of transfers before rearbitrating among the requesting channels again. The arbitration size can be configured for each channel, ranging from 1 to 1024 item transfers. After the μDMA controller transfers the number of items specified by the arbitration size, it then checks among all the channels making a request and services the channel with the highest priority.

If a lower priority μDMA channel uses a large arbitration size, the latency for higher priority channels is increased because the μDMA controller completes the lower priority burst before checking for higher priority requests. Therefore, lower priority channels should not use a large arbitration size for best response on high priority channels.

The arbitration size can also be thought of as a burst size. It is the maximum number of items that are transferred at any one time in a burst. Here, the term arbitration refers to determination of μDMA channel priority, not arbitration for the bus. When the μDMA controller arbitrates for the bus, the processor always takes priority. Furthermore, the μDMA controller is held off whenever the processor must perform a bus transaction on the same bus, even in the middle of a burst transfer.

9.2.4 Request Types

The μDMA controller responds to two types of requests from a peripheral: single or burst. Each peripheral may support either or both types of requests. A single request means that the peripheral is ready to transfer one item, while a burst request means that the peripheral is ready to transfer multiple items.

The μDMA controller responds differently depending on whether the peripheral is making a single request or a burst request. If both are asserted, and the μDMA channel has been set up for a burst transfer, then the burst request takes precedence. See Table 9-2 on page 709, which shows how each peripheral supports the two request types.

Table 9-2. Request Type Support

Peripheral	Event that generates Single Request	Event that generates Burst Request
ADC	FIFO not empty	FIFO half full
EPI WFIFO	None	WFIFO Level (configurable)
EPI NBRFIFO	None	NBRFIFO Level (configurable)
General-Purpose Timer	None	Trigger event
GPIO	None	Trigger event
I ² C TX	TX Buffer Not Full	TX FIFO Level (configurable)
I ² C RX	RX Buffer Not Empty	RX FIFO Level (configurable)

Table 9-2. Request Type Support (continued)

Peripheral	Event that generates Single Request	Event that generates Burst Request
SSI TX	TX FIFO Not Full	TX FIFO Level (fixed at 4)
SSI RX	RX FIFO Not Empty	RX FIFO Level (fixed at 4)
UART TX	TX FIFO Not Full	TX FIFO Level (configurable)
UART RX	RX FIFO Not Empty	RX FIFO Level (configurable)
SHA/MD5	None	Context In DMA request (SHA/MD5 0 Cin) Context Out DMA request (SHA/MD5 0 Cout) Data In DMA request (SHA/MD5 0 Din)
AES	None	Context In DMA request (AES0 Cin) Context Out DMA request (AES0 Cout) Data In DMA request (AES0 Din) Data Out DMA request (AES0 Dout)
DES	None	Context In DMA request (DES0 Cin) Data In DMA request (DES0 Din) Data Out DMA request (DES0 Dout)

9.2.4.1 Single Request

When a single request is detected, and not a burst request, the μ DMA controller transfers one item and then stops to wait for another request.

9.2.4.2 Burst Request

When a burst request is detected, the μ DMA controller transfers the number of items that is the lesser of the arbitration size or the number of items remaining in the transfer. Therefore, the arbitration size should be the same as the number of data items that the peripheral can accommodate when making a burst request. For example, the UART generates a burst request based on the FIFO trigger level. In this case, the arbitration size should be set to the amount of data that the FIFO can transfer when the trigger level is reached. A burst transfer runs to completion once it is started, and cannot be interrupted, even by a higher priority channel. Burst transfers complete in a shorter time than the same number of non-burst transfers.

It may be desirable to use only burst transfers and not allow single transfers. For example, perhaps the nature of the data is such that it only makes sense when transferred together as a single unit rather than one piece at a time. The single request can be disabled by using the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register. By setting the bit for a channel in this register, the μ DMA controller only responds to burst requests for that channel.

9.2.5 Channel Configuration

The μ DMA controller uses an area of system memory to store a set of channel control structures in a table. The control table may have one or two entries for each μ DMA channel. Each entry in the table structure contains source and destination pointers, transfer size, and transfer mode. The control table can be located anywhere in system memory, but it must be contiguous and aligned on a 1024-byte boundary.

Table 9-3 on page 711 shows the layout in memory of the channel control table. Each channel may have one or two control structures in the control table: a primary control structure and an optional alternate control structure. The table is organized so that all of the primary entries are in the first half of the table, and all the alternate structures are in the second half of the table. The primary entry is used for simple transfer modes where transfers can be reconfigured and restarted after each

transfer is complete. In this case, the alternate control structures are not used and therefore only the first half of the table must be allocated in memory; the second half of the control table is not necessary, and that memory can be used for something else. If a more complex transfer mode is used such as ping-pong or scatter-gather, then the alternate control structure is also used and memory space should be allocated for the entire table.

Any unused memory in the control table may be used by the application. This includes the control structures for any channels that are unused by the application as well as the unused control word for each channel.

Table 9-3. Control Structure Memory Map

Offset	Channel
0x0	0, Primary
0x10	1, Primary
...	...
0x1F0	31, Primary
0x200	0, Alternate
0x210	1, Alternate
...	...
0x3F0	31, Alternate

Table 9-4 shows an individual control structure entry in the control table. Each entry is aligned on a 16-byte boundary. The entry contains four long words: the source end pointer, the destination end pointer, the control word, and an unused entry. The end pointers point to the ending address of the transfer and are inclusive. If the source or destination is non-incrementing (as for a peripheral register), then the pointer should point to the transfer address.

Table 9-4. Channel Control Structure

Offset	Description
0x000	Source End Pointer
0x004	Destination End Pointer
0x008	Control Word
0x00C	Unused

The control word contains the following fields:

- Source and destination data sizes
- Source and destination address increment size
- Number of transfers before bus arbitration
- Total number of items to transfer
- Useburst flag
- Transfer mode

The control word and each field are described in detail in “μDMA Channel Control Structure” on page 729. The μDMA controller updates the transfer size and transfer mode fields as the transfer is performed. At the end of a transfer, the transfer size indicates 0, and the transfer

mode indicates "stopped." Because the control word is modified by the μ DMA controller, it must be reconfigured before each new transfer. The source and destination end pointers are not modified, so they can be left unchanged if the source or destination addresses remain the same.

Prior to starting a transfer, a μ DMA channel must be enabled by setting the appropriate bit in the **DMA Channel Enable Set (DMAENASET)** register. A channel can be disabled by setting the channel bit in the **DMA Channel Enable Clear (DMAENACLR)** register. At the end of a complete μ DMA transfer, the controller automatically disables the channel.

9.2.6 Transfer Modes

The μ DMA controller supports several transfer modes. Two of the modes support simple one-time transfers. Several complex modes support a continuous flow of data.

9.2.6.1 Stop Mode

While Stop is not actually a transfer mode, it is a valid value for the mode field of the control word. When the mode field has this value, the μ DMA controller does not perform any transfers and disables the channel if it is enabled. At the end of a transfer, the μ DMA controller updates the control word to set the mode to Stop.

9.2.6.2 Basic Mode

In Basic mode, the μ DMA controller performs transfers as long as there are more items to transfer, and a transfer request is present. This mode is used with peripherals that assert a μ DMA request signal whenever the peripheral is ready for a data transfer. Basic mode should not be used in any situation where the request is momentary even though the entire transfer should be completed. For example, a software-initiated transfer creates a momentary request, and in Basic mode, only the number of transfers specified by the ARBSIZE field in the **DMA Channel Control Word (DMACHCTL)** register is transferred on a software request, even if there is more data to transfer.

When all of the items have been transferred using Basic mode, the μ DMA controller sets the mode for that channel to Stop.

BASIC mode can be programmed to ignore when XFERSIZE reaches 0x000 and continue copying on request until the channel is stopped manually. If the NXTUSEBURST bit in the **uDMA Channel Control Word (DMACHCTL)** register is set while in BASIC mode and the XFERSIZE reaches 0x000 and is not written back, transfers continue until the request is deasserted by the peripheral.

9.2.6.3 Auto Mode

Auto mode is similar to Basic mode, except that once a transfer request is received, the transfer runs to completion, even if the μ DMA request is removed. This mode is suitable for software-triggered transfers. Generally, Auto mode is not used with a peripheral.

When all the items have been transferred using Auto mode, the μ DMA controller sets the mode for that channel to Stop.

9.2.6.4 Ping-Pong

Ping-Pong mode is used to support a continuous data flow to or from a peripheral. To use Ping-Pong mode, both the primary and alternate data structures must be implemented. Both structures are set up by the processor for data transfer between memory and a peripheral. The transfer is started using the primary control structure. When the transfer using the primary control structure is complete, the μ DMA controller reads the alternate control structure for that channel to continue the transfer. Each time this happens, an interrupt is generated, and the processor can reload the control structure for the just-completed transfer. Data flow can continue indefinitely this way, using the primary and

alternate control structures to switch back and forth between buffers as the data flows to or from the peripheral.

Refer to Figure 9-2 on page 713 for an example showing operation in Ping-Pong mode.

Figure 9-2. Example of Ping-Pong µDMA Transaction

9.2.6.5 Memory Scatter-Gather

Memory Scatter-Gather mode is a complex mode used when data must be transferred to or from varied locations in memory instead of a set of contiguous locations in a memory buffer. For example, a gather μ DMA operation could be used to selectively read the payload of several stored packets of a communication protocol and store them together in sequence in a memory buffer.

In Memory Scatter-Gather mode, the primary control structure is used to program the alternate control structure from a table in memory. The table is set up by the processor software and contains a list of control structures, each containing the source and destination end pointers, and the control word for a specific transfer. The mode of each control word must be set to Scatter-Gather mode. Each entry in the table is copied in turn to the alternate structure where it is then executed. The μ DMA controller alternates between using the primary control structure to copy the next transfer instruction from the list and then executing the new transfer instruction. The end of the list is marked by programming the control word for the last entry to use Auto transfer mode. Once the last transfer is performed using Auto mode, the μ DMA controller stops. A completion interrupt is generated only after the last transfer. It is possible to loop the list by having the last entry copy the primary control structure to point back to the beginning of the list (or to a new list). It is also possible to trigger a set of other channels to perform a transfer, either directly, by programming a write to the software trigger for another channel, or indirectly, by causing a peripheral action that results in a μ DMA request.

By programming the μ DMA controller using this method, a set of up to 256 arbitrary transfers can be performed based on a single μ DMA request.

Refer to Figure 9-3 on page 715 and Figure 9-4 on page 716, which show an example of operation in Memory Scatter-Gather mode. This example shows a *gather* operation, where data in three separate buffers in memory is copied together into one buffer. Figure 9-3 on page 715 shows how the application sets up a μ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 9-4 on page 716 shows the sequence as the μ DMA controller performs the three sets of copy operations. First, using the primary control structure, the μ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the destination buffer. Next, the μ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

Figure 9-3. Memory Scatter-Gather, Setup and Configuration**NOTES:**

1. Application has a need to copy data items from three separate locations in memory into one combined buffer.
2. Application sets up μ DMA “task list” in memory, which contains the pointers and control configuration for three μ DMA copy “tasks.”
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the μ DMA controller.
4. The SRC and DST pointers in the task list must point to the last location in the corresponding buffer.

Figure 9-4. Memory Scatter-Gather, μ DMA Copy Sequence

Using the channel's primary control structure, the μ DMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer A to the destination buffer.

Using the channel's primary control structure, the μ DMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer B to the destination buffer.

Using the channel's primary control structure, the μ DMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer C to the destination buffer.

9.2.6.6 Peripheral Scatter-Gather

Peripheral Scatter-Gather mode is very similar to Memory Scatter-Gather, except that the transfers are controlled by a peripheral making a μDMA request. Upon detecting a request from the peripheral, the μDMA controller uses the primary control structure to copy one entry from the list to the alternate control structure and then performs the transfer. At the end of this transfer, the primary control structure will copy the next task to the alternate control structure . If the next task is a memory-to-memory transfer, execution will start immediately and run to completion; if the next task is a peripheral-type transfer, the μDMA will wait for a peripheral request to begin.

By using this method, the μDMA controller can transfer data to or from a peripheral from a set of arbitrary locations whenever the peripheral is ready to transfer data.

Refer to Figure 9-5 on page 718 and Figure 9-6 on page 719, which show an example of operation in Peripheral Scatter-Gather mode. This example shows a gather operation, where data from three separate buffers in memory is copied to a single peripheral data register. Figure 9-5 on page 718 shows how the application sets up a μDMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that is used for the operation is configured to copy from the task list to the alternate control structure.

Figure 9-6 on page 719 shows the sequence as the μDMA controller performs the three sets of copy operations. First, using the primary control structure, the μDMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the peripheral data register. Next, the μDMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

Figure 9-5. Peripheral Scatter-Gather, Setup and Configuration**NOTES:**

1. Application has a need to copy data items from three separate locations in memory into a peripheral data register.
2. Application sets up μ DMA “task list” in memory, which contains the pointers and control configuration for three μ DMA copy “tasks.”
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it is executed by the μ DMA controller.

Figure 9-6. Peripheral Scatter-Gather, μDMA Copy Sequence

Using the channel's primary control structure, the μDMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μDMA controller copies data from the source buffer A to the peripheral data register.

Using the channel's primary control structure, the μDMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μDMA controller copies data from the source buffer B to the peripheral data register.

Using the channel's primary control structure, the μDMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μDMA controller copies data from the source buffer C to the peripheral data register.

9.2.7 Transfer Size and Increment

The μ DMA controller supports transfer data sizes of 8, 16, or 32 bits. The source and destination data size must be the same for any given transfer. The source and destination address can be auto-incremented by bytes, half-words, or words, or can be set to no increment. The source and destination address increment values can be set independently, and it is not necessary for the address increment to match the data size as long as the increment is the same or larger than the data size. For example, it is possible to perform a transfer using 8-bit data size, but using an address increment of full words (4 bytes). The data to be transferred must be aligned in memory according to the data size (8, 16, or 32 bits).

Table 9-5 shows the configuration to read from a peripheral that supplies 8-bit data.

Table 9-5. μ DMA Read Example: 8-Bit Peripheral

Field	Configuration
Source data size	8 bits
Destination data size	8 bits
Source address increment	No increment
Destination address increment	Byte
Source end pointer	Peripheral read FIFO register
Destination end pointer	End of the data buffer in memory

9.2.8 Peripheral Interface

There are three main classes of uDMA-connected peripherals:

- Peripherals with FIFOs serviced by the uDMA to transmit or receive data.
- Peripherals that provide trigger inputs to the uDMA

9.2.8.1 FIFO Peripherals

FIFO peripherals contain a FIFO of data to be sent and a FIFO of data that has been received. The uDMA controller is used to transfer data between these FIFOs and system memory. For example, when a UART FIFO contains one or more entries, a single transfer request is sent to the uDMA for processing. If this request has not been processed and the UART FIFO reaches the interrupt FIFO level set in the **UART Interrupt FIFO Level Select (UARTIFLS)** register, another interrupt is sent to the uDMA which is higher priority than the single-transfer request. In this instance, an ARBSIZ transfer is performed as configured in the **DMACHCTL** register. After the transfer is complete, the DMA sends a receive or transmit complete interrupt to the **UART Raw Interrupt Status (UARTRIS)** register.

If the FIFO peripheral's SETn bit is set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register, then the uDMA will only perform transfers defined by the ARBSIZ bit field in the **DMACHCTL** register for better bus utilization. For peripherals that tend to transmit and receive in bursts, such as the UART, we recommend against the use of this configuration since it could cause the tail end of transmissions to stick in the FIFO.

9.2.8.2 Trigger Peripherals

Certain peripherals, such as the general purpose timer, trigger an interrupt to the uDMA controller when a programmed event occurs. When a trigger event occurs, the uDMA executes a transfer defined by the ARBSIZ bit field in the **DMACHCTL** register. If only a single transfer is needed for a uDMA trigger, then the ARBSIZ field is set to 0x1.

If the trigger peripheral generates another uDMA request while the prior one is being serviced and that particular channel is the highest priority asserted channel, the second request will be processed as soon as the handling of the first is complete. If two additional trigger peripheral uDMA requests are generated prior to the completion of the first, the third request is lost.

9.2.9 Software Request

A transfer is initiated by software by first configuring and enabling the transfer, and then issuing a software request using the **DMA Channel Software Request (DMASWREQ)** register. For software-based transfers, the Auto transfer mode should be used.

It is possible to initiate a transfer on any available software channel using the **DMASWREQ** register. If a request is initiated by software using a peripheral μDMA channel, then the completion interrupt occurs on the interrupt vector for the peripheral instead of the software interrupt vector. Any peripheral channel may be used for software requests as long as the corresponding peripheral is not using μDMA for data transfer.

Note: Channels designated in the table as only "Software" are dedicated software channels. When only one software request is required in an application, dedicated software channels can be used. If multiple software requests in code are required, then peripheral channel software requests should be used for proper μDMA completion acknowledgement.

9.2.10 Interrupts and Errors

Depending on the peripheral, the μDMA can indicate transfer completion at the end of an entire transfer or when a FIFO or buffer reaches a certain level (see Table 9-2 on page 709 and the individual peripheral chapters). When a μDMA transfer is complete, a `dma_done` signal is sent to the peripheral that initiated the μDMA event. Interrupts can be enabled within the peripheral to trigger on μDMA transfer completion. Please refer to the individual peripheral chapters for more information on peripheral μDMA interrupts. If the transfer uses the software μDMA channel, then the completion interrupt occurs on the dedicated software μDMA interrupt vector (see Table 9-6 on page 721).

If the μDMA controller encounters a bus or memory protection error as it attempts to perform a data transfer, it disables the μDMA channel that caused the error and generates an interrupt on the μDMA error interrupt vector. The processor can read the **DMA Bus Error Clear (DMAERRCLR)** register to determine if an error is pending. The `ERRCLR` bit is set if an error occurred. The error can be cleared by writing a 1 to the `ERRCLR` bit.

Table 9-6 shows the dedicated interrupt assignments for the μDMA controller.

Table 9-6. μDMA Interrupt Assignments

Interrupt	Assignment
44	μDMA Software Channel Transfer
45	μDMA Error

9.3 Initialization and Configuration

9.3.1 Module Initialization

Before the μDMA controller can be used, it must be enabled in the System Control block and in the peripheral. The location of the channel control structure must also be programmed.

The following steps should be performed one time during system initialization:

1. Enable the μDMA clock using the **RCGCDMA** register (see page 401).

2. Enable the μ DMA controller by setting the MASTEREN bit of the **DMA Configuration (DMACFG)** register.
3. Program the location of the channel control table by writing the base address of the table to the **DMA Channel Control Base Pointer (DMACTLBASE)** register. The base address must be aligned on a 1024-byte boundary.

9.3.2 Configuring a Memory-to-Memory Transfer

μ DMA channel 30 is dedicated for software-initiated transfers. However, any channel can be used for software-initiated, memory-to-memory transfer if the associated peripheral is not being used.

9.3.2.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Program bit 30 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 30 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 30 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μ DMA controller to respond to single and burst requests.
4. Set bit 30 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μ DMA controller to recognize requests for this channel.

9.3.2.2 Configure the Channel Control Structure

Now the channel control structure must be configured.

This example transfers 256 words from one memory buffer to another. Channel 30 is used for a software transfer, and the control structure for channel 30 is at offset 0x1E0 of the channel control table. The channel control structure for channel 30 is located at the offsets shown in Table 9-7.

Table 9-7. Channel Control Structure Offsets for Channel 30

Offset	Description
Control Table Base + 0x1E0	Channel 30 Source End Pointer
Control Table Base + 0x1E4	Channel 30 Destination End Pointer
Control Table Base + 0x1E8	Channel 30 Control Word

Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive).

1. Program the source end pointer at offset 0x1E0 to the address of the source buffer + 0x3FC.
2. Program the destination end pointer at offset 0x1E4 to the address of the destination buffer + 0x3FC.

The control word at offset 0x1E8 must be programmed according to Table 9-8.

Table 9-8. Channel Control Word Configuration for Memory Transfer Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	2	32-bit destination address increment
DSTSIZE	29:28	2	32-bit destination data size
SRCINC	27:26	2	32-bit source address increment
SRCSIZE	25:24	2	32-bit source data size
reserved	23:22	0	Reserved
DSTPROT0 ^a	21	0	Privileged access protection for destination data writes
reserved	20:19	0	Reserved
SRCPROT0 ^a	18	0	Privileged access protection for source data reads
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	255	Transfer 256 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	2	Use Auto-request transfer mode

a. The value of this bit must be 1 (privileged) for AES, DES, or SHA accesses.

Configure Peripheral Interrupts

For memory-to-memory transfers, the peripheral involved must be configured to generate an interrupt when the µDMA has completed its transfer. Upon completion, the µDMA will send a `dma_done` signal to the peripheral.

9.3.2.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 30 of the **DMA Channel Enable Set (DMAENASET)** register.
2. Issue a transfer request by setting bit 30 of the **DMA Channel Software Request (DMASWREQ)** register.

The µDMA transfer begins. If the interrupt is enabled, then the processor is notified by interrupt when the transfer is complete. If needed, the status can be checked by reading bit 30 of the **DMAENASET** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the `XFERMODE` field of the channel control word at offset 0x1E8. This field is automatically cleared at the end of the transfer.

9.3.3 Configuring a Peripheral for Simple Transmit

This example configures the µDMA controller to transmit a buffer of data to a peripheral. The peripheral has a transmit FIFO with a trigger level of 4. The example peripheral uses µDMA channel 7.

9.3.3.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 7 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.

2. Set bit 7 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 7 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μ DMA controller to respond to single and burst requests.
4. Set bit 7 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μ DMA controller to recognize requests for this channel.

9.3.3.2 Configure the Channel Control Structure

This example transfers 64 bytes from a memory buffer to the peripheral's transmit FIFO register using μ DMA channel 7. The control structure for channel 7 is at offset 0x070 of the channel control table. The channel control structure for channel 7 is located at the offsets shown in Table 9-9.

Table 9-9. Channel Control Structure Offsets for Channel 7

Offset	Description
Control Table Base + 0x070	Channel 7 Source End Pointer
Control Table Base + 0x074	Channel 7 Destination End Pointer
Control Table Base + 0x078	Channel 7 Control Word

Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register.

1. Program the source end pointer at offset 0x070 to the address of the source buffer + 0x3F.
2. Program the destination end pointer at offset 0x074 to the address of the peripheral's transmit FIFO register.

The control word at offset 0x078 must be programmed according to Table 9-10.

Table 9-10. Channel Control Word Configuration for Peripheral Transmit Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	3	Destination address does not increment
DSTSIZE	29:28	0	8-bit destination data size
SRCINC	27:26	0	8-bit source address increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:22	0	Reserved
DSTPROT0 ^a	21	0	Privileged access protection for destination data writes
reserved	20:19	0	Reserved
SRCPROT0 ^a	18	0	Privileged access protection for source data reads
ARBSIZE	17:14	2	Arbitrates after 4 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	1	Use Basic transfer mode

a. The value of this bit must be 1 (privileged) for AES, DES, or SHA accesses.

Note: In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 4, the arbitration size is set to 4. If the peripheral does make a burst request, then 4 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any space in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst SET[7] bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

9.3.3.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 7 of the **DMA Channel Enable Set (DMAENASET)** register.

The μDMA controller is now configured for transfer on channel 7. The controller makes transfers to the peripheral whenever the peripheral asserts a μDMA request. The transfers continue until the entire buffer of 64 bytes has been transferred. When that happens, the μDMA controller disables the channel and sets the **XFERMODE** field of the channel control word to 0 (Stopped). The status of the transfer can be checked by reading bit 7 of the **DMA Channel Enable Set (DMAENASET)** register. This bit is automatically cleared when the transfer is complete. The status can also be checked by reading the **XFERMODE** field of the channel control word at offset 0x078. This field is automatically cleared at the end of the transfer.

If peripheral interrupts are enabled, then the peripheral generates an interrupt when the entire transfer is complete.

9.3.4 Configuring a Peripheral for Ping-Pong Receive

This example configures the μDMA controller to continuously receive 8-bit data from a peripheral into a pair of 64-byte buffers. The peripheral has a receive FIFO with a trigger level of 8. The example peripheral uses μDMA channel 8.

9.3.4.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Configure bit 8 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 8 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 8 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μDMA controller to respond to single and burst requests.
4. Set bit 8 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μDMA controller to recognize requests for this channel.

9.3.4.2 Configure the Channel Control Structure

This example transfers bytes from the peripheral's receive FIFO register into two memory buffers of 64 bytes each. As data is received, when one buffer is full, the μDMA controller switches to use the other.

To use Ping-Pong buffering, both primary and alternate channel control structures must be used. The primary control structure for channel 8 is at offset 0x080 of the channel control table, and the

alternate channel control structure is at offset 0x280. The channel control structures for channel 8 are located at the offsets shown in Table 9-11.

Table 9-11. Primary and Alternate Channel Control Structure Offsets for Channel 8

Offset	Description
Control Table Base + 0x080	Channel 8 Primary Source End Pointer
Control Table Base + 0x084	Channel 8 Primary Destination End Pointer
Control Table Base + 0x088	Channel 8 Primary Control Word
Control Table Base + 0x280	Channel 8 Alternate Source End Pointer
Control Table Base + 0x284	Channel 8 Alternate Destination End Pointer
Control Table Base + 0x288	Channel 8 Alternate Control Word

Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Because the peripheral pointer does not change, it simply points to the peripheral's data register. Both the primary and alternate sets of pointers must be configured.

1. Program the primary source end pointer at offset 0x080 to the address of the peripheral's receive buffer.
2. Program the primary destination end pointer at offset 0x084 to the address of ping-pong buffer A + 0x3F.
3. Program the alternate source end pointer at offset 0x280 to the address of the peripheral's receive buffer.
4. Program the alternate destination end pointer at offset 0x284 to the address of ping-pong buffer B + 0x3F.

The primary control word at offset 0x088 and the alternate control word at offset 0x288 are initially programmed the same way.

1. Program the primary channel control word at offset 0x088 according to Table 9-12.
2. Program the alternate channel control word at offset 0x288 according to Table 9-12.

Table 9-12. Channel Control Word Configuration for Peripheral Ping-Pong Receive Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	0	8-bit destination address increment
DSTSIZEx	29:28	0	8-bit destination data size
SRCINC	27:26	3	Source address does not increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:22	0	Reserved
DSTPROT0	21	0	Privileged access protection for destination data writes
reserved	20:19	0	Reserved
SRCPROT0	18	0	Privileged access protection for source data reads
ARBSIZE	17:14	3	Arbitrates after 8 transfers

**Table 9-12. Channel Control Word Configuration for Peripheral Ping-Pong Receive Example
(continued)**

Field in DMACHCTL	Bits	Value	Description
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	3	Use Ping-Pong transfer mode

Note: In this example, it is not important if the peripheral makes a single request or a burst request. Because the peripheral has a FIFO that triggers at a level of 8, the arbitration size is set to 8. If the peripheral does make a burst request, then 8 bytes are transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any data in the FIFO), then one byte is transferred at a time. If it is important to the application that transfers only be made in bursts, then the Channel Useburst SET[8] bit should be set in the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

9.3.4.3 Configure the Peripheral Interrupt

An interrupt handler should be configured when using µDMA Ping-Pong mode, it is best to use an interrupt handler. However, the Ping-Pong mode can be configured without interrupts by polling. The interrupt handler is triggered after each buffer is complete.

1. Configure and enable an interrupt handler for the peripheral.

9.3.4.4 Enable the µDMA Channel

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 8 of the **DMA Channel Enable Set (DMAENASET)** register.

9.3.4.5 Process Interrupts

The µDMA controller is now configured and enabled for transfer on channel 8. When the peripheral asserts the µDMA request signal, the µDMA controller makes transfers into buffer A using the primary channel control structure. When the primary transfer to buffer A is complete, it switches to the alternate channel control structure and makes transfers into buffer B. At the same time, the primary channel control word mode field is configured to indicate Stopped, and an interrupt is generated in the peripheral's raw interrupt status register.

When an interrupt is triggered, the interrupt handler must determine which buffer is complete and process the data or set a flag that the data must be processed by non-interrupt buffer processing code. Then the next buffer transfer must be set up.

In the interrupt handler:

1. Read the primary channel control word at offset 0x088 and check the XFERMODE field. If the field is 0, this means buffer A is complete. If buffer A is complete, then:
 - a. Process the newly received data in buffer A or signal the buffer processing code that buffer A has data available.
 - b. Reprogram the primary channel control word at offset 0x88 according to Table 9-12 on page 726.
2. Read the alternate channel control word at offset 0x288 and check the XFERMODE field. If the field is 0, this means buffer B is complete. If buffer B is complete, then:

- a. Process the newly received data in buffer B or signal the buffer processing code that buffer B has data available.
- b. Reprogram the alternate channel control word at offset 0x288 according to Table 9-12 on page 726.

9.3.5 Configuring Channel Assignments

Channel assignments for each μ DMA channel can be changed using the **DMACHMAPn** registers. Each 4-bit field represents a μ DMA channel.

Refer to Table 9-1 on page 707 for channel assignments.

For example, to use UART1 RX on channel 8, configure the CH8SEL bit in the **DMACHMAP1** register to be 0x1. If a peripheral is enabled on two different channels, the μ DMA channel that has the highest priority for that peripheral takes precedence. Thus, if UART 1 RX is enabled on both channel 8 and channel 22, the UART1 RX channel 22 priority needs to be lowered before channel 8 UART1 RX can be accessed by the μ DMA.

9.4 Register Map

Table 9-13 on page 728 lists the μ DMA channel control structures and registers. The channel control structure shows the layout of one entry in the channel control table. The channel control table is located in system memory, and the location is determined by the application, thus the base address is n/a (not applicable) and noted as such above the register descriptions. In the table below, the offset for the channel control structures is the offset from the entry in the channel control table. See “Channel Configuration” on page 710 and Table 9-3 on page 711 for a description of how the entries in the channel control table are located in memory. The μ DMA register addresses are given as a hexadecimal increment, relative to the μ DMA base address of 0x400F.F000. Note that the μ DMA module clock must be enabled before the registers can be programmed (see page 401). There must be a delay of 3 system clocks after the μ DMA module clock is enabled before any μ DMA module registers are accessed.

Table 9-13. μ DMA Register Map

Offset	Name	Type	Reset	Description	See page
μDMA Channel Control Structure (Offset from Channel Control Table Base)					
0x000	DMASRCENDP	RW	-	DMA Channel Source Address End Pointer	730

9.5 µDMA Channel Control Structure

The µDMA Channel Control Structure holds the transfer settings for a µDMA channel. Each channel has two control structures, which are located in a table in system memory. Refer to “Channel Configuration” on page 710 for an explanation of the Channel Control Table and the Channel Control Structure.

The channel control structure is one entry in the channel control table. Each channel has a primary and alternate structure. The primary control structures are located at offsets 0x0, 0x10, 0x20 and so on. The alternate control structures are located at offsets 0x200, 0x210, 0x220, and so on.

Register 1: DMA Channel Source Address End Pointer (DMASRCENDP), offset 0x000

DMA Channel Source Address End Pointer (DMASRCENDP) is part of the Channel Control Structure and is used to specify the source address for a μ DMA transfer.

Note: The offset specified is from the base address of the control structure in system memory, not the μ DMA module base address.

DMA Channel Source Address End Pointer (DMASRCENDP)

Base n/a
Offset 0x000
Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	RW	-	<p>Source Address End Pointer</p> <p>This field points to the last address of the μDMA transfer source (inclusive). If the source address is not incrementing (the SRCINC field in the DMACHCTL register is 0x3), then this field points at the source location itself (such as a peripheral data register).</p>

Register 2: DMA Channel Destination Address End Pointer (DMADSTENDP), offset 0x004

DMA Channel Destination Address End Pointer (DMADSTENDP) is part of the Channel Control Structure and is used to specify the destination address for a µDMA transfer.

Note: The offset specified is from the base address of the control structure in system memory, not the µDMA module base address.

DMA Channel Destination Address End Pointer (DMADSTENDP)

Base n/a
Offset 0x004
Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	RW	-	<p>Destination Address End Pointer</p> <p>This field points to the last address of the µDMA transfer destination (inclusive). If the destination address is not incrementing (the DSTINC field in the DMACHCTL register is 0x3), then this field points at the destination location itself (such as a peripheral data register).</p>

Register 3: DMA Channel Control Word (DMACHCTL), offset 0x008

DMA Channel Control Word (DMACHCTL) is part of the Channel Control Structure and is used to specify parameters of a μ DMA transfer.

Note: The offset specified is from the base address of the control structure in system memory, not the μ DMA module base address.

DMA Channel Control Word (DMACHCTL)

Base n/a
Offset 0x008
Type RW, reset -

0x4	16 Transfers																											
0x5	32 Transfers																											
0x6	64 Transfers																											
0x7	128 Transfers																											
0x8	256 Transfers																											
0x9	512 Transfers																											
0xA-0xF	1024 Transfers In this configuration, no arbitration occurs during the μ DMA transfer because the maximum transfer size is 1024.																											

Bit/Field	Name	Type	Reset	Description																		
13:4	XFERSIZE	RW	-	<p>Transfer Size (minus 1)</p> <p>This field configures the total number of items to transfer. The value of this field is 1 less than the number to transfer (value 0 means transfer 1 item). The maximum value for this 10-bit field is 1023 which represents a transfer size of 1024 items.</p> <p>The transfer size is the number of items, not the number of bytes. If the data size is 32 bits, then this value is the number of 32-bit words to transfer.</p> <p>The µDMA controller updates this field immediately prior to entering the arbitration process, so it contains the number of outstanding items that is necessary to complete the µDMA cycle.</p>																		
3	NXTUSEBURST	RW	-	<p>Next Useburst</p> <p>This field controls whether the Useburst SET[n] bit is automatically set for the last transfer of a peripheral scatter-gather operation. Normally, for the last transfer, if the number of remaining items to transfer is less than the arbitration size, the µDMA controller uses single transfers to complete the transaction. If this bit is set, then the controller uses a burst transfer to complete the last transfer.</p>																		
2:0	XFERMODE	RW	-	<p>µDMA Transfer Mode</p> <p>This field configures the operating mode of the µDMA cycle. Refer to "Transfer Modes" on page 712 for a detailed explanation of transfer modes.</p> <p>Because this register is in system RAM, it has no reset value. Therefore, this field should be initialized to 0 before the channel is enabled.</p> <table> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Stop</td> </tr> <tr> <td>0x1</td> <td>Basic</td> </tr> <tr> <td>0x2</td> <td>Auto-Request</td> </tr> <tr> <td>0x3</td> <td>Ping-Pong</td> </tr> <tr> <td>0x4</td> <td>Memory Scatter-Gather</td> </tr> <tr> <td>0x5</td> <td>Alternate Memory Scatter-Gather</td> </tr> <tr> <td>0x6</td> <td>Peripheral Scatter-Gather</td> </tr> <tr> <td>0x7</td> <td>Alternate Peripheral Scatter-Gather</td> </tr> </tbody> </table>	Value	Description	0x0	Stop	0x1	Basic	0x2	Auto-Request	0x3	Ping-Pong	0x4	Memory Scatter-Gather	0x5	Alternate Memory Scatter-Gather	0x6	Peripheral Scatter-Gather	0x7	Alternate Peripheral Scatter-Gather

0x4	Memory Scatter-Gather																					
0x5	Alternate Memory Scatter-Gather																					
0x6	Peripheral Scatter-Gather																					
0x7	Alternate Peripheral Scatter-Gather																					

XFERMODE Bit Field Values.

Stop

Channel is stopped or configuration data is invalid. No more transfers can occur.

Basic

For each trigger (whether from a peripheral or a software request), the µDMA controller performs the number of transfers specified by the ARBSIZE field.

Auto-Request

The initial request (software- or peripheral-initiated) is sufficient to complete the entire transfer of XFERSIZE items without any further requests.

Ping-Pong

This mode uses both the primary and alternate control structures for this channel. When the number of transfers specified by the XFERSIZE field have completed for the current control structure (primary or alternate), the μ DMA controller switches to the other one. These switches continue until one of the control structures is not set to ping-pong mode. At that point, the μ DMA controller stops. An interrupt is generated on completion of the transfers configured by each control structure. See “Ping-Pong” on page 712.

Memory Scatter-Gather

When using this mode, the primary control structure for the channel is configured to allow a list of operations (tasks) to be performed. The source address pointer specifies the start of a table of tasks to be copied to the alternate control structure for this channel. The XFERMODE field for the alternate control structure should be configured to 0x5 (Alternate memory scatter-gather) to perform the task. When the task completes, the μ DMA switches back to the primary channel control structure, which then copies the next task to the alternate control structure. This process continues until the table of tasks is empty. The last task must have an XFERMODE value other than 0x5. Note that for continuous operation, the last task can update the primary channel control structure back to the start of the list or to another list. See “Memory Scatter-Gather” on page 714.

Alternate Memory Scatter-Gather

This value must be used in the alternate channel control data structure when the μ DMA controller operates in Memory Scatter-Gather mode.

Peripheral Scatter-Gather

This value must be used in the primary channel control data structure when the μ DMA controller operates in Peripheral Scatter-Gather mode. In this mode, the μ DMA controller operates exactly the same as in Memory Scatter-Gather mode, except that instead of performing the number of transfers specified by the XFERSIZE field in the alternate control structure at one time, the μ DMA controller only performs the number of transfers specified by the ARBSIZE field per trigger; see Basic mode for details. See “Peripheral Scatter-Gather” on page 717.

Alternate Peripheral Scatter-Gather

This value must be used in the alternate channel control data structure when the μ DMA controller operates in Peripheral Scatter-Gather mode.

9.6 μ DMA Register Descriptions

The register addresses given are relative to the μ DMA base address of 0x400F.F000.

Register 4: DMA Status (DMASTAT), offset 0x000

The **DMA Status (DMASTAT)** register returns the status of the µDMA controller. You cannot read this register when the µDMA controller is in the reset state.

DMA Status (DMASTAT)

Base 0x400F.F000
Offset 0x000
Type RO, reset 0x001F.0000

Bit/Field	Name	Type	Reset	Description
31:21	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20:16	DMACHANS	RO	0x1F	Available µDMA Channels Minus 1 This field contains a value equal to the number of µDMA channels the µDMA controller is configured to use, minus one. The value of 0x1F corresponds to 32 µDMA channels.
15:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:4	STATE	RO	0x0	Control State Machine Status This field shows the current status of the control state machine. Status can be one of the following.
		Value	Description	
		0x0	Idle	
		0x1	Reading channel controller data.	
		0x2	Reading source end pointer.	
		0x3	Reading destination end pointer.	
		0x4	Reading source data.	
		0x5	Writing destination data.	
		0x6	Waiting for µDMA request to clear.	
		0x7	Writing channel controller data.	
		0x8	Stalled	
		0x9	Done	
		0xA-0xF	Undefined	
3:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
0	MASTEN	RO	0	Master Enable Status
				Value Description
			0	The μ DMA controller is disabled.
			1	The μ DMA controller is enabled.

Register 5: DMA Configuration (DMACFG), offset 0x004

The **DMACFG** register controls the configuration of the µDMA controller.

DMA Configuration (DMACFG)

Base 0x400F.F000

Offset 0x004

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:1	reserved	WO	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	MASTEN	WO	-	Controller Master Enable
		Value	Description	
		0	Disables the µDMA controller.	
		1	Enables µDMA controller.	

Register 6: DMA Channel Control Base Pointer (DMACTLBASE), offset 0x008

The **DMACTLBASE** register must be configured so that the base pointer points to a location in system memory.

The amount of system memory that must be assigned to the μ DMA controller depends on the number of μ DMA channels used and whether the alternate channel control data structure is used. See “Channel Configuration” on page 710 for details about the Channel Control Table. The base address must be aligned on a 1024-byte boundary. This register cannot be read when the μ DMA controller is in the reset state.

DMA Channel Control Base Pointer (DMACTLBASE)

Base 0x400F.F000
Offset 0x008
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:10	ADDR	RW	0x0000.00	Channel Control Base Address This field contains the pointer to the base address of the channel control table. The base address must be 1024-byte aligned.
9:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 7: DMA Alternate Channel Control Base Pointer (DMAALTBASE), offset 0x00C

The **DMAALTBASE** register returns the base address of the alternate channel control data. This register removes the necessity for application software to calculate the base address of the alternate channel control structures. This register cannot be read when the µDMA controller is in the reset state.

DMA Alternate Channel Control Base Pointer (DMAALTBASE)

Base 0x400F.F000
Offset 0x00C
Type RO, reset 0x0000.0200

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	RO	0x0000.0200	Alternate Channel Address Pointer This field provides the base address of the alternate channel control structures.

Register 8: DMA Channel Wait-on-Request Status (DMAWAITSTAT), offset 0x010

This read-only register indicates that the μ DMA channel is waiting on a request. A peripheral can hold off the μ DMA from performing a single request until the peripheral is ready for a burst request to enhance the μ DMA performance. The use of this feature is dependent on the design of the peripheral and is not controllable by software in any way. This register cannot be read when the μ DMA controller is in the reset state.

DMA Channel Wait-on-Request Status (DMAWAITSTAT)

Base 0x400F.F000
Offset 0x010
Type RO, reset 0x03C3.CF00

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WAITREQ[n]															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	1	1	1	1	0	0	0	0	0	1	1
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WAITREQ[n]															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	1	1	0	0	1	1	1	1	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	WAITREQ[n]	RO	0x03C3.CF00	Channel [n] Wait Status
These bits provide the channel wait-on-request status. Bit 0 corresponds to channel 0.				
				Value Description
				0 The corresponding channel is not waiting on a request.
				1 The corresponding channel is waiting on a request.

Register 9: DMA Channel Software Request (DMASWREQ), offset 0x014

Each bit of the **DMASWREQ** register represents the corresponding µDMA channel. Setting a bit generates a request for the specified µDMA channel.

DMA Channel Software Request (DMASWREQ)

Base 0x400F.F000

Offset 0x014

Type WO, reset -

Bit/Field Name Type Reset Description

31:0	SWREQ[n]	WO	-	Channel [n] Software Request These bits generate software requests. Bit 0 corresponds to channel 0.
------	-----------------	----	---	--

Value Description

0 No request generated.

1 Generate a software request for the corresponding channel.

These bits are automatically cleared when the software request has been completed.

Register 10: DMA Channel Useburst Set (DMAUSEBURSTSET), offset 0x018

Each bit of the **DMAUSEBURSTSET** register represents the corresponding μ DMA channel. Setting a bit disables the channel's single request input from generating requests, configuring the channel to only accept burst requests. Reading the register returns the status of USEBURST.

If the amount of data to transfer is a multiple of the arbitration (burst) size, the corresponding SET[n] bit is cleared after completing the final transfer. If there are fewer items remaining to transfer than the arbitration (burst) size, the μ DMA controller automatically clears the corresponding SET[n] bit, allowing the remaining items to transfer using single requests. In order to resume transfers using burst requests, the corresponding bit must be set again. A bit should not be set if the corresponding peripheral does not support the burst request model.

Refer to “Request Types” on page 709 for more details about request types.

DMA Channel Useburst Set (DMAUSEBURSTSET)

Base 0x400F.F000
Offset 0x018
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	RW	0x0000.0000	Channel [n] Useburst Set
Value Description				
0 μ DMA channel [n] responds to single or burst requests.				
1 μ DMA channel [n] responds only to burst requests.				
Bit 0 corresponds to channel 0. This bit is automatically cleared as described above. A bit can also be manually cleared by setting the corresponding CLR[n] bit in the DMAUSEBURSTCLR register.				

Register 11: DMA Channel Useburst Clear (DMAUSEBURSTCLR), offset 0x01C

Each bit of the **DMAUSEBURSTCLR** register represents the corresponding µDMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAUSEBURSTSET** register.

DMA Channel Useburst Clear (DMAUSEBURSTCLR)

Base 0x400F.F000

Offset 0x01C

Type WO, reset -

Bit/Field Name Type Reset Description

31:0 CLR[n] WO - Channel [n] Useburst Clear

Value Description

0 No effect.

1 Setting a bit clears the corresponding **SET[n]** bit in the **DMAUSEBURSTSET** register meaning that µDMA channel [n] responds to single and burst requests.

Register 12: DMA Channel Request Mask Set (DMAREQMASKSET), offset 0x020

Each bit of the **DMAREQMASKSET** register represents the corresponding μ DMA channel. Setting a bit disables μ DMA requests for the channel. Reading the register returns the request mask status. When a μ DMA channel's request is masked, that means the peripheral can no longer request μ DMA transfers. The channel can then be used for software-initiated transfers.

DMA Channel Request Mask Set (DMAREQMASKSET)

Base 0x400F.F000
Offset 0x020
Type RW, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Type	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	SET[n]	RW	0x0000.0000	Channel [n] Request Mask Set
------	--------	----	-------------	------------------------------

Value	Description
-------	-------------

- | | |
|---|--|
| 0 | The peripheral associated with channel [n] is enabled to request μ DMA transfers. |
| 1 | The peripheral associated with channel [n] is not able to request μ DMA transfers. Channel [n] may be used for software-initiated transfers. |

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding CLR[n] bit in the **DMAREQMASKCLR** register.

Register 13: DMA Channel Request Mask Clear (DMAREQMASKCLR), offset 0x024

Each bit of the **DMAREQMASKCLR** register represents the corresponding µDMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAREQMASKSET** register.

DMA Channel Request Mask Clear (DMAREQMASKCLR)

Base 0x400F.F000

Offset 0x024

Type WO, reset -

31:0	CLR[n]	WO	-	Channel [n] Request Mask Clear
Value Description				
0 No effect.				Setting a bit clears the corresponding SET[n] bit in the DMAREQMASKSET register meaning that the peripheral associated with channel [n] is enabled to request µDMA transfers.
1				

Register 14: DMA Channel Enable Set (DMAENASET), offset 0x028

Each bit of the **DMAENASET** register represents the corresponding μ DMA channel. Setting a bit enables the corresponding μ DMA channel. Reading the register returns the enable status of the channels. If a channel is enabled but the request mask is set (**DMAREQMASKSET**), then the channel can be used for software-initiated transfers.

DMA Channel Enable Set (DMAENASET)

Base 0x400F.F000
Offset 0x028
Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0 SET[n] RW 0x0000.0000 Channel [n] Enable Set

Value Description

- 0 μ DMA Channel [n] is disabled.
- 1 μ DMA Channel [n] is enabled.

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding CLR[n] bit in the **DMAENACLR** register or when the end of a μ DMA transfer occurs.

Register 15: DMA Channel Enable Clear (DMAENACLR), offset 0x02C

Each bit of the **DMAENACLR** register represents the corresponding µDMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAENASET** register.

DMA Channel Enable Clear (DMAENACLR)

Base 0x400F.F000

Offset 0x02C

Type WO, reset -

------	--------	----	---	--------------------------------

Value	Description
-------	-------------

0	No effect.
---	------------

1	Setting a bit clears the corresponding SET[n] bit in the DMAENASET register meaning that channel [n] is disabled for µDMA transfers.
---	--

Note: The controller disables a channel when it completes the µDMA cycle.

Register 16: DMA Channel Primary Alternate Set (DMAALTSET), offset 0x030

Each bit of the **DMAALTSET** register represents the corresponding μ DMA channel. Setting a bit configures the μ DMA channel to use the alternate control data structure. Reading the register returns the status of which control data structure is in use for the corresponding μ DMA channel.

DMA Channel Primary Alternate Set (DMAALTSET)

Base 0x400F.F000
Offset 0x030
Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0 SET[n] RW 0x0000.0000 Channel [n] Alternate Set

Value Description

- 0 μ DMA channel [n] is using the primary control structure.
- 1 μ DMA channel [n] is using the alternate control structure.

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding CLR[n] bit in the **DMAALTCLR** register.

Note: For Ping-Pong and Scatter-Gather cycle types, the μ DMA controller automatically sets these bits to select the alternate channel control data structure.

Register 17: DMA Channel Primary Alternate Clear (DMAALTCLR), offset 0x034

Each bit of the **DMAALTCLR** register represents the corresponding µDMA channel. Setting a bit clears the corresponding `SET[n]` bit in the **DMAALTSET** register.

DMA Channel Primary Alternate Clear (DMAALTCLR)

Base 0x400F.F000

Offset 0x034

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	CLR[n]	WO	-	Channel [n] Alternate Clear
Value Description				
0 No effect.				
1 Setting a bit clears the corresponding <code>SET[n]</code> bit in the DMAALTSET register meaning that channel [n] is using the primary control structure.				

Note: For Ping-Pong and Scatter-Gather cycle types, the µDMA controller automatically sets these bits to select the alternate channel control data structure.

Register 18: DMA Channel Priority Set (DMAPRIOSET), offset 0x038

Each bit of the **DMAPRIOSET** register represents the corresponding μ DMA channel. Setting a bit configures the μ DMA channel to have a high priority level. Reading the register returns the status of the channel priority mask.

DMA Channel Priority Set (DMAPRIOSET)

Base 0x400F.F000
Offset 0x038
Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0 SET[n] RW 0x0000.0000 Channel [n] Priority Set

Value Description

0 μ DMA channel [n] is using the default priority level.

1 μ DMA channel [n] is using a high priority level.

Bit 0 corresponds to channel 0. A bit can only be cleared by setting the corresponding CLR[n] bit in the **DMAPRIOCLR** register.

Register 19: DMA Channel Priority Clear (DMAPRIOCLR), offset 0x03C

Each bit of the **DMAPRIOCLR** register represents the corresponding µDMA channel. Setting a bit clears the corresponding **SET[n]** bit in the **DMAPRIOSET** register.

DMA Channel Priority Clear (DMAPRIOCLR)

Base 0x400F.F000

Offset 0x03C

Type WO, reset -

Bit/Field Name Type Reset Description

31:0 CLR[n] WO - Channel [n] Priority Clear

Value Description

0 No effect.

1 Setting a bit clears the corresponding **SET[n]** bit in the **DMAPRIOSET** register meaning that channel [n] is using the default priority level.

Register 20: DMA Bus Error Clear (DMAERRCLR), offset 0x04C

The **DMAERRCLR** register is used to read and clear the μ DMA bus error status. The error status is set if the μ DMA controller encountered a bus error while performing a transfer. If a bus error occurs on a channel, that channel is automatically disabled by the μ DMA controller. The other channels are unaffected.

DMA Bus Error Clear (DMAERRCLR)

Base 0x400F.F000
Offset 0x04C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	ERRCLR	RW1C	0	μ DMA Bus Error Status

Value	Description
0	No bus error is pending.
1	A bus error is pending.

This bit is cleared by writing a 1 to it.

Register 21: DMA Channel Assignment (DMACHASGN), offset 0x500

Each bit of the **DMACHASGN** register represents the corresponding µDMA channel. Setting a bit selects the secondary channel assignment as specified in Table 9-1 on page 707.

Note: This register is provided to support legacy software. New software should use the **DMACHMAPn** registers. If a bit is clear in this register, the corresponding field in the **DMACHMAPn** registers is configured to 0x0. If a bit is set in this register, the corresponding field is configured to 0x1. If this register is read, a bit reads as 0 if the corresponding **DMACHMAPn** register field value is equal to 0, otherwise it reads as 1 if the corresponding **DMACHMAPn** register field value is not equal to 0.

DMA Channel Assignment (DMACHASGN)

Base 0x400F.F000
Offset 0x500
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	CHASGN[n]	RW	-	Channel [n] Assignment Select
				Value Description
				0 Use the primary channel assignment.
				1 Use the secondary channel assignment.

Register 22: DMA Channel Map Select 0 (DMACHMAP0), offset 0x510

Each 4-bit field of the **DMACHMAP0** register configures the μ DMA channel assignment as specified in Table 9-1 on page 707.

Note: To support legacy software which uses the **DMA Channel Assignment (DMACHASGN)** register, a value of 0x0 is equivalent to a **DMACHASGN** bit being clear, and a value of 0x1 is equivalent to a **DMACHASGN** bit being set.

DMA Channel Map Select 0 (DMACHMAP0)

Base 0x400F.F000

Register 23: DMA Channel Map Select 1 (DMACHMAP1), offset 0x514

Each 4-bit field of the **DMACHMAP1** register configures the µDMA channel assignment as specified in Table 9-1 on page 707.

Note: To support legacy software which uses the **DMA Channel Assignment (DMACHASGN)** register, a value of 0x0 is equivalent to a **DMACHASGN** bit being clear, and a value of 0x1 is equivalent to a **DMACHASGN** bit being set.

Register 29: DMA Peripheral Identification 3 (DMAPeriphID3), offset 0xFEC

The **DMAPeriphIDn** registers are hard-coded and the fields within the registers determine the reset values.

DMA Peripheral Identification 3 (DMAPeriphID3)

Base 0x400F.F000
Offset 0xFEC
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID3	RO	0x00	μDMA Peripheral ID Register [31:24] Can be used by software to identify the presence of this peripheral.

Register 30: DMA Peripheral Identification 4 (DMAPeriphID4), offset 0xFD0

The **DMAPeriphIDn** registers are hard-coded, and the fields within the registers determine the reset values.

DMA Peripheral Identification 4 (DMAPeriphID4)

Base 0x400F.F000
Offset 0xFD0
Type RO, reset 0x0000.0004

Register 31: DMA PrimeCell Identification 0 (DMACellID0), offset 0xFF0

The **DMACellIDn** registers are hard-coded, and the fields within the registers determine the reset values.

DMA PrimeCell Identification 0 (DMACellID0)

Base 0x400F.F000
Offset 0xFF0
Type RO, reset 0x0000.000D

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CID0	RO	0x0D	μDMA PrimeCell ID Register [7:0] Provides software a standard cross-peripheral identification system.

Register 32: DMA PrimeCell Identification 1 (DMAPCellID1), offset 0xFF4

The **DMAPCellIDn** registers are hard-coded, and the fields within the registers determine the reset values.

DMA PrimeCell Identification 1 (DMAPCellID1)

Base 0x400F.F000
Offset 0xFF4
Type RO, reset 0x0000.00F0

Register 33: DMA PrimeCell Identification 2 (DMAPCellID2), offset 0xFF8

The **DMAPCellIDn** registers are hard-coded, and the fields within the registers determine the reset values.

DMA PrimeCell Identification 2 (DMAPCellID2)

Base 0x400F.F000
Offset 0xFF8
Type RO, reset 0x0000.0005

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CID2	RO	0x05	μDMA PrimeCell ID Register [23:16] Provides software a standard cross-peripheral identification system.

Register 34: DMA PrimeCell Identification 3 (DMA_PCellID3), offset 0xFFC

The **DMAPCellIDn** registers are hard-coded, and the fields within the registers determine the reset values.

DMA PrimeCell Identification 3 (DMA_{PC}ID3)

Base 0x400F.F000
Offset 0xFFC
Type RO, reset 0x0000.00B1

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CID3	RO	0xB1	μDMA PrimeCell ID Register [31:24] Provides software a standard cross-peripheral identification system.

10 General-Purpose Input/Outputs (GPIOs)

The GPIO module is composed of physical GPIO blocks, each corresponding to an individual GPIO port (Port A, Port B, Port C, Port D, Port E, Port F, Port G, Port H, Port J, Port K, Port L, Port M, Port N, Port P, Port Q, Port R, Port S, Port T). The GPIO module supports up to 140 programmable input/output pins, depending on the peripherals being used.

The GPIO module has the following features:

- Up to 140 GPIOs, depending on configuration
- Highly flexible pin muxing allows use as GPIO or one of several peripheral functions
- 3.3-V-tolerant in input configuration
- Advanced High Performance Bus accesses all ports:
 - Ports A-H and J; Ports K-N and P-T
- Fast toggle capable of a change every clock cycle for ports on AHB
- Programmable control for GPIO interrupts
 - Interrupt generation masking
 - Edge-triggered on rising, falling, or both
 - Level-sensitive on High or Low values
 - Per-pin interrupts available on Port P and Port Q
- Bit masking in both read and write operations through address lines
- Can be used to initiate an ADC sample sequence or a µDMA transfer
- Pin state can be retained during Hibernation mode; pins on port P can be programmed to wake on level in Hibernation mode
- Pins configured as digital inputs are Schmitt-triggered
- Programmable control for GPIO pad configuration
 - Weak pull-up or pull-down resistors
 - 2-mA, 4-mA, 6-mA, 8-mA, 10-mA and 12-mA pad drive for digital communication; up to four pads can sink 18-mA for high-current applications
 - Slew rate control for 8-mA, 10-mA and 12-mA pad drive
 - Open drain enables
 - Digital input enables

10.1 Signal Description

GPIO signals have alternate hardware functions. The following table lists the GPIO pins and their analog and digital alternate functions. All GPIO signals are 5-V tolerant when configured as inputs except for PB0 and PB1, which are limited to 3.6 V. The digital alternate hardware functions are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the PMC_x bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Analog signals in the table below are also 3.3-V tolerant and are configured by clearing the DEN bit in the **GPIO Digital Enable (GPIODEN)** register. The AIN_x analog signals have internal circuitry to protect them from voltages over V_{DD} (up to the maximum specified in Table 32-1 on page 2099), but analog performance specifications are only guaranteed if the input signal swing at the I/O pad is kept inside the range 0 V < V_{IN} < V_{DD}. Note that each pin must be programmed individually; no type of grouping is implied by the columns in the table. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, **GPIOPUR=0**, and **GPIOPCTL=0**), with the exception of the pins shown in the table below. A Power-On-Reset (**POR**) puts the pins back to their default state.

Table 10-1. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 781.

Note: If the device fails initialization during reset, the hardware toggles the TDO output as an indication of failure. Thus, during board layout, designers should not designate the TDO pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

a. The TMPRn signals are digital signals enabled and configured by the Hibernation module. All other signals listed in this column are analog signals.

b. The digital signals that are shaded gray are the power-on default values for the corresponding GPIO pin. Encodings 9, 10, and 12 are not used on this device.

10.2 Pad Capabilities

There are two main types of pads provided on the device:

- Fast GPIO pads: These pads provide variable, programmable drive strength and optimized voltage output levels.
- Slow GPIO pads: These pads provide 2-mA drive strength and are designed to be sensitive to voltage inputs. The following GPIOs port pins are designed with Slow GPIO Pads:
 - PJ1

Please refer to “Recommended GPIO Operating Characteristics” on page 2101 for details on the GPIO operating conditions for these two different pad types.

Note: Port pins PL6 and PL7 operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**.

Note: Port pins PM[7:4] operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins.

10.3 Functional Description

Each GPIO port is a separate hardware instantiation of the same physical block (see Figure 10-1 on page 776 and Figure 10-2 on page 777). The TM4C129XKCZAD microcontroller contains 18 ports and thus of these physical GPIO blocks. Note that not all pins are implemented on every block. Some GPIO pins can function as I/O signals for the on-chip peripheral modules. For information on which GPIO pins are used for alternate hardware functions, refer to Table 31-5 on page 2085.

Figure 10-1. Digital I/O Pads

Figure 10-2. Analog/Digital I/O Pads

10.3.1 Data Control

The data control registers allow software to configure the operational modes of the GPIOs. The data direction register configures the GPIO as an input or an output while the data register either captures incoming data or drives it out to the pads.

Caution – It is possible to create a software sequence that prevents the debugger from connecting to the TM4C129XKCZAD microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger. In the case that the software routine is not implemented and the device is locked out of the part, this issue can be solved by using the TM4C129XKCZAD Flash Programmer "Unlock" feature. Please refer to [LMFLASHPROGRAMMER](#) on the TI web for more information.

10.3.1.1 Data Direction Operation

The **GPIO Direction (GPIODIR)** register (see page 789) is used to configure each individual pin as an input or output. When the data direction bit is cleared, the GPIO is configured as an input, and the corresponding data register bit captures and stores the value on the GPIO port. When the data direction bit is set, the GPIO is configured as an output, and the corresponding data register bit is driven out on the GPIO port.

10.3.1.2 Data Register Operation

To aid in the efficiency of software, the GPIO ports allow for the modification of individual bits in the **GPIO Data (GPIODATA)** register (see page 788) by using bits [9:2] of the address bus as a mask. In this manner, software drivers can modify individual GPIO pins in a single instruction without affecting the state of the other pins. This method is more efficient than the conventional method of performing a read-modify-write operation to set or clear an individual GPIO pin. To implement this feature, the **GPIODATA** register covers 256 locations in the memory map.

During a write, if the address bit associated with that data bit is set, the value of the **GPIODATA** register is altered. If the address bit is cleared, the data bit is left unchanged.

For example, writing a value of 0xEB to the address GPIODATA + 0x098 has the results shown in Figure 10-3, where *u* indicates that data is unchanged by the write. This example demonstrates how **GPIODATA** bits 5, 2, and 1 are written.

Figure 10-3. GPIODATA Write Example

During a read, if the address bit associated with the data bit is set, the value is read. If the address bit associated with the data bit is cleared, the data bit is read as a zero, regardless of its actual value. For example, reading address GPIODATA + 0x0C4 yields as shown in Figure 10-4. This example shows how to read **GPIODATA** bits 5, 4, and 0.

Figure 10-4. GPIODATA Read Example

10.3.2 Interrupt Control

The interrupt capabilities of each GPIO port are controlled by a set of seven registers. These registers are used to select the source of the interrupt, its polarity, and the edge properties. When one or more GPIO inputs cause an interrupt, a single interrupt output is sent to the interrupt controller for the entire GPIO port. For edge-triggered interrupts, software must clear the interrupt to enable any further interrupts. For a level-sensitive interrupt, the external source must hold the level constant for the interrupt to be recognized by the controller.

Three registers define the edge or sense that causes interrupts:

- **GPIO Interrupt Sense (GPIOIS)** register (see page 790)
- **GPIO Interrupt Both Edges (GPIOIBE)** register (see page 791)
- **GPIO Interrupt Event (GPIOIEV)** register (see page 792)

Interrupts are enabled/disabled via the **GPIO Interrupt Mask (GPIOIM)** register (see page 793).

When an interrupt condition occurs, the state of the interrupt signal can be viewed in two locations: the **GPIO Raw Interrupt Status (GPIORIS)** and **GPIO Masked Interrupt Status (GPIOIMIS)** registers (see page 794 and page 796). As the name implies, the **GPIOIMIS** register only shows interrupt conditions that are allowed to be passed to the interrupt controller. The **GPIORIS** register indicates that a GPIO pin meets the conditions for an interrupt, but has not necessarily been sent to the interrupt controller.

For a GPIO level-detect interrupt, the interrupt signal generating the interrupt must be held until serviced. Once the input signal deasserts from the interrupt generating logical sense, the corresponding **RIS** bit in the **GPIORIS** register clears. For a GPIO edge-detect interrupt, the **RIS** bit in the **GPIORIS** register is cleared by writing a ‘1’ to the corresponding bit in the **GPIO Interrupt Clear (GPIOICR)** register (see page 798). The corresponding **GPIOIMIS** bit reflects the masked value of the **RIS** bit.

When programming the interrupt control registers (**GPIOIS**, **GPIOIBE**, or **GPIOIEV**), the interrupts should be masked (**GPIOIM** cleared). Writing any value to an interrupt control register can generate a spurious interrupt if the corresponding bits are enabled.

10.3.2.1 Interrupts Per Pin

Each pin of GPIO Port P and Port Q can trigger an interrupt. Each pin has a dedicated interrupt vector and can be handled by a separate interrupt handler. The **P_P0** and **P_Q0** interrupts serve as a master interrupt and provide a legacy aggregated interrupt version. For interrupt assignments, see Table 2-9 on page 125.

Note: The OR'ed summary interrupt occurs on bit 0 of the **GPIORIS** register. For summary interrupt mode, software should set the **GPIOIM** register to 0xFF and mask the port pin interrupts 1 through 7 in the **Interrupt Clear Enable (DISn)** register (see “NVIC Register Descriptions” on page 163). When servicing this interrupt, write a 1 to the corresponding bit in the **UNPENDn** register to clear the pending interrupt in the NVIC and clear the **GPIORIS** register pin interrupt bits by setting the **IC** field of the **GPIOICR** register to 0xFF.

10.3.2.2 ADC Trigger Source

Any GPIO pin can be configured to be an external trigger for the ADC using the **GPIO ADC Control (GPIOADCCTL)** register. If any GPIO is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set), and an interrupt for that port is generated, a trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger,

an ADC conversion is initiated. See page 1237. Note that whether the GPIO is configured to trigger on edge events or level events, a single-clock ADC trigger pulse is created in either event. Thus, when a level event is selected, the ADC sample sequence will run only one time and multiple sample sequences will not be executed if the level remains the same. It is recommended that edge events be used as ADC trigger source.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous devices to operate on this microcontroller.

10.3.2.3 μDMA Trigger Source

Any GPIO pin can be configured to be an external trigger for the μDMA using the **GPIO DMA Control (GPIODMACTL)** register. If any GPIO is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set), a `dma_req` signal is sent to the μDMA. If the μDMA is configured to start a transfer based on the GPIO signal, a transfer is initiated. When transfer is complete, the `dma_done` signal is sent from the μDMA to the GPIO and is reported as a DMA (done) interrupt in the **GPIOISR** register.

10.3.2.4 HIB Wake Source

GPIO pins K[7:4] on Port K can be configured as an external wake source for the hibernation (HIB) module. The pins can be configured in the following way:

1. Write 0x0000.0040 to the **HIBCTL** register at offset 0x010 to enable 32.768-kHz Hibernation oscillator.
2. Write any data to be retained during power cut to the **HIBDATA** register at offsets 0x030-0x06F.
3. Configure the **GPIOWAKEPEN** and **GPIOWAKELVL** registers at offsets 0x540 and 0x544 in the GPIO module. Enable the I/O wake pad configuration by writing 0x0000.0001 to the **HIBIO** register at offset 0x010.
4. When the `IOWRC` bit in the **HIBIO** register is read as 1, write 0x0000.0000 to the **HIBO** register to lock the current pad configuration so that any other writes to the **GPIOWAKEPEN** and **GPIOWAKELVL** register will be ignored.
5. The hibernation sequence may be initiated by writing 0x0000.0052 to the **HIBCTL** register.

The **GPIOWAKESTAT** register at offset 0x548 can be read to determine which port caused a wake pin assertion.

10.3.3 Mode Control

The GPIO pins can be controlled by either software or hardware. Software control is the default for most signals and corresponds to the GPIO mode, where the **GPIODATA** register is used to read or write the corresponding pins. When hardware control is enabled via the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 799), the pin state is controlled by its alternate function (that is, the peripheral).

Further pin muxing options are provided through the **GPIO Port Control (GPIOPCTL)** register which selects one of several peripheral functions for each GPIO. For information on the configuration options, refer to Table 31-5 on page 2085.

Note: If any pin is to be used as an ADC input, the appropriate bit in the **GPIOAMSEL** register must be set to disable the analog isolation circuit.

10.3.4 Commit Control

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the `NMI` pin (see “Signal Tables” on page 2032 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 799), **GPIO Pull Up Select (GPIOPUR)** register (see page 805), **GPIO Pull-Down Select (GPIOPDR)** register (see page 807), and **GPIO Digital Enable (GPIODEN)** register (see page 810) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 812) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 813) have been set.

10.3.5 Pad Control

The pad control registers allow software to configure the GPIO pads based on the application requirements. The pad control registers include the **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOODR**, **GPIOPUR**, **GPIOPDR**, **GPIOSLR**, and **GPIODEN** registers. These registers control drive strength, open-drain configuration, pull-up and pull-down resistors, slew-rate control and digital input enable for each GPIO. If 3.3V is applied to a GPIO configured as an open-drain output, the output voltage will depend on the strength of your pull-up resistor. The GPIO pad is not electrically configured to output 3.3 V.

Note: Port pins `PL6` and `PL7` operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**.

Note: Port pins `PM[7:4]` operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins.

10.3.5.1 Extended Drive Enable

The **GPIO Peripheral Configuration (GPIOPC)** register controls the extended drive modes of the GPIO. When the `EDE` bit in **GPIO Peripheral Properties (GPIOPP)** register is set and the `EDMn` bit field for a GPIO pin is non-zero in the **GPIOPC** register, the **GPIODRnR** registers do not drive their default value, but instead output an incremental drive strength, which has an additive effect. This allows for more drive strength possibilities. When the `EDE` bit is set and the `EDMn` bit field is non-zero, the 2 mA driver is always enabled. Any bits enabled in the **GPIODR4R** register for a pin with a non-zero `EDMn` value, add an additional 2 mA. Any bits set in the **GPIODR8R** add an extra 4 mA of drive. The **GPIODR12R** register is only valid when the `EDMn` value is 0x3. For this encoding, setting a bit in the **GPIODR12R** register adds 4 mA of drive to the already existing 8 mA, for a 12 mA drive strength. To attain a 10-mA drive strength, the pin's **GPIODR12R** and **GPIODR8R** register should be enabled; this would result in the addition of two, 4-mA current drivers to the already enabled 2-mA driver. The table below shows the drive capability options. If `EDMn` is 0x00, then the **GPIODR2R**, **GPIODR4R**, and **GPIODR8R** function as stated in their default register description.

Note: A **GPIOPC** register write must precede the configuration of the **GPIODRnR** registers in order for extended drive mode to take effect.

Table 10-3. GPIO Drive Strength Options

EDE (GPIOPP)	EDMn (GPIOPC)	GPIODR12R (+4mA)	GPIODR8R (+4mA)	GPIODR4R (+2mA)	GPIODR2R (2mA)	Drive (mA)
X	0x0	N/A	0	0	1	2
			0	1	0	4
			1	0	0	8
1	0x1	N/A	0	0	N/A	2
			0	1	N/A	4
			1	0	N/A	6
			1	1	N/A	8
1	0x3	0	0	0	N/A	2
		0	0	1	N/A	4
		0	1	0	N/A	6
		0	1	1	N/A	8
		1	1	0	N/A	10
		1	1	1	N/A	12
		1	0	N/A	N/A	N/A
1	0x2	N/A	N/A	N/A	N/A	N/A

10.3.6 Identification

The identification registers configured at reset allow software to detect and identify the module as a GPIO block. The identification registers include the **GPIOPeriphID0-GPIOPeriphID7** registers as well as the **GPIOCellIID0-GPIOCellIID3** registers.

10.4 Initialization and Configuration

To configure the GPIO pins of a particular port, follow these steps:

1. Enable the clock to the port by setting the appropriate bits in the **RCGCGPIO** register (see page 398). In addition, the **SCGCGPIO** and **DCGCGPIO** registers can be programmed in the same manner to enable clocking in Sleep and Deep-Sleep modes.
2. Set the direction of the GPIO port pins by programming the **GPIODIR** register. A write of a 1 indicates output and a write of a 0 indicates input.
3. Configure the **GPIOAFSEL** register to program each bit as a GPIO or alternate pin. If an alternate pin is chosen for a bit, then the **PMCx** field must be programmed in the **GPIOPCTL** register for the specific peripheral required. There are also two registers, **GPIOADCCTL** and **GPIODMACTL**, which can be used to program a GPIO pin as a ADC or µDMA trigger, respectively.
4. Set the **EDMn** field in the **GPIOPC** register as shown in Table 10-3 on page 782.
5. Set or clear the **GPIODR4R** register bits as shown in Table 10-3 on page 782.
6. Set or clear the **GPIODR8R** register bits as shown in Table 10-3 on page 782.
7. Set or clear the **GPIODR12R** register bits as shown in Table 10-3 on page 782.

8. Program each pad in the port to have either pull-up, pull-down, or open drain functionality through the **GPIOPUR**, **GPIOPDR**, **GPIOODR** register. Slew rate may also be programmed, if needed, through the **GPIOOSLR** register.
9. To enable GPIO pins as digital I/Os, set the appropriate **DEN** bit in the **GPIODEN** register. To enable GPIO pins to their analog function (if available), set the **GPIOAMSEL** bit in the **GPIOAMSEL** register.
10. Program the **GPIOIS**, **GPIOIBE**, **GPIOBE**, **GPIOEV**, and **GPIOIM** registers to configure the type, event, and mask of the interrupts for each port.
11. Optionally, software can lock the configurations of the NMI and JTAG/SWD pins on the GPIO port pins, by setting the **LOCK** bits in the **GPIOLOCK** register.

When the internal POR signal is asserted and until otherwise configured, all GPIO pins are configured to be undriven (tristate): **GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, and **GPIOPUR**=0Table 10-4 on page 783 shows all possible configurations of the GPIO pads and the control register settings required to achieve them. Table 10-5 on page 784 shows how a rising edge interrupt is configured for pin 2 of a GPIO port.

Table 10-4. GPIO Pad Configuration Examples

Configuration	GPIO Register Bit Value ^a										
	AFSEL	DIR	ODR	DEN	PUR	PDR	DR2R	DR4R	DR8R	DR12R	SLR

GPIOIM	0=masked 1=not masked	0	0	0	0	0	1	0	0	

a. X=Ignored (don't care bit)

10.5 Register Map

Table 10-7 on page 785 lists the GPIO registers.

Important: The GPIO registers in this chapter are duplicated in each GPIO block; however, depending on the block, all eight bits may not be connected to a GPIO pad. In those cases, writing to unconnected bits has no effect, and reading unconnected bits returns no meaningful data. See “Signal Description” on page 770 for the GPIOs included on this device.

The offset listed is a hexadecimal increment to the register's address, relative to that GPIO port's base address:

- GPIO Port A (AHB): 0x4005.8000
- GPIO Port B (AHB): 0x4005.9000
- GPIO Port C (AHB): 0x4005.A000
- GPIO Port D (AHB): 0x4005.B000
- GPIO Port E (AHB): 0x4005.C000
- GPIO Port F (AHB): 0x4005.D000
- GPIO Port G (AHB): 0x4005.E000
- GPIO Port H (AHB): 0x4005.F000
- GPIO Port J (AHB): 0x4006.0000
- GPIO Port K (AHB): 0x4006.1000
- GPIO Port L (AHB): 0x4006.2000
- GPIO Port M (AHB): 0x4006.3000
- GPIO Port N (AHB): 0x4006.4000
- GPIO Port P (AHB): 0x4006.5000
- GPIO Port Q (AHB): 0x4006.6000
- GPIO Port R (AHB): 0x4006.7000
- GPIO Port S (AHB): 0x4006.8000
- GPIO Port T (AHB): 0x4006.9000

Note that each GPIO module clock must be enabled before the registers can be programmed (see page 398). There must be a delay of 3 system clocks after the GPIO module clock is enabled before any GPIO module registers are accessed.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, **GPIOPUR=0**, and **GPIOPCTL=0**), with the exception of the pins shown in the table below. A Power-On-Reset ($\overline{\text{POR}}$) puts the pins back to their default state.

Table 10-6. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 781.

Note: If the device fails initialization during reset, the hardware toggles the **TDO** output as an indication of failure. Thus, during board layout, designers should not designate the **TDO** pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

The default register type for the **GPIOCR** register is RO for all GPIO pins with the exception of the **NMI** pin and the four JTAG/SWD pins (see “Signal Tables” on page 2032 for pin numbers). These six pins are the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for the corresponding GPIO Ports is RW.

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the **NMI** pin and the four JTAG/SWD pins (see “Signal Tables” on page 2032 for pin numbers). To ensure that the JTAG and **NMI** pins are not accidentally programmed as GPIO pins, these pins default to non-committable. Because of this, the default reset value of **GPIOCR** changes for the corresponding ports.

10.6 Register Descriptions

The remainder of this section lists and describes the GPIO registers, in numerical order by address offset.

Register 1: GPIO Data (GPIO DATA), offset 0x000

The **GPIO DATA** register is the data register. In software control mode, values written in the **GPIO DATA** register are transferred onto the GPIO port pins if the respective pins have been configured as outputs through the **GPIO Direction (GPIO DIR)** register (see page 789).

In order to write to **GPIO DATA**, the corresponding bits in the mask, resulting from the address bus bits [9:2], must be set. Otherwise, the bit values remain unchanged by the write.

Similarly, the values read from this register are determined for each bit by the mask bit derived from the address used to access the data register, bits [9:2]. Bits that are set in the address mask cause the corresponding bits in **GPIO DATA** to be read, and bits that are clear in the address mask cause the corresponding bits in **GPIO DATA** to be read as 0, regardless of their value.

A read from **GPIO DATA** returns the last bit value written if the respective pins are configured as outputs, or it returns the value on the corresponding input pin when these are configured as inputs. All bits are cleared by a reset.

GPIO Data (GPIO DATA)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (AHB) base: 0x4005.F000

GPIO Port J (AHB) base: 0x4006.0000

GPIO Port K (AHB) base: 0x4006.1000

GPIO Port L (AHB) base: 0x4006.2000

GPIO Port M (AHB) base: 0x4006.3000

GPIO Port N (AHB) base: 0x4006.4000

GPIO Port P (AHB) base: 0x4006.5000

GPIO Port Q (AHB) base: 0x4006.6000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x000

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	RW	0x00	<p>GPIO Data</p> <p>This register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and written to the registers are masked by the eight address lines [9:2]. Reads from this register return its current state. Writes to this register only affect bits that are not masked by ADDR[9:2] and are configured as outputs. See “Data Register Operation” on page 778 for examples of reads and writes.</p>

Register 2: GPIO Direction (GPIODIR), offset 0x400

The **GPIODIR** register is the data direction register. Setting a bit in the **GPIODIR** register configures the corresponding pin to be an output, while clearing a bit configures the corresponding pin to be an input. All bits are cleared by a reset, meaning all GPIO pins are inputs by default.

GPIO Direction (GPIODIR)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (AHB) base: 0x4005.F000

GPIO Port J (AHB) base: 0x4006.0000

GPIO Port K (AHB) base: 0x4006.1000

GPIO Port L (AHB) base: 0x4006.2000

GPIO Port M (AHB) base: 0x4006.3000

GPIO Port N (AHB) base: 0x4006.4000

GPIO Port P (AHB) base: 0x4006.5000

GPIO Port Q (AHB) base: 0x4006.6000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x400

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DIR	RW	0x00	GPIO Data Direction
				Value Description
			0	Corresponding pin is an input.
			1	Corresponding pins is an output.

Register 3: GPIO Interrupt Sense (GPIOIS), offset 0x404

The **GPIOIS** register is the interrupt sense register. Setting a bit in the **GPIOIS** register configures the corresponding pin to detect levels, while clearing a bit configures the corresponding pin to detect edges. All bits are cleared by a reset.

GPIO Interrupt Sense (GPIOIS)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (AHB) base: 0x4005.F000

GPIO Port J (AHB) base: 0x4006.0000

GPIO Port K (AHB) base: 0x4006.1000

GPIO Port L (AHB) base: 0x4006.2000

GPIO Port M (AHB) base: 0x4006.3000

GPIO Port N (AHB) base: 0x4006.4000

GPIO Port P (AHB) base: 0x4006.5000

GPIO Port Q (AHB) base: 0x4006.6000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x404

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IS	RW	0x00	GPIO Interrupt Sense
		Value	Description	
		0	The edge on the corresponding pin is detected (edge-sensitive).	
		1	The level on the corresponding pin is detected (level-sensitive).	

Register 4: GPIO Interrupt Both Edges (GPIOIBE), offset 0x408

The **GPIOIBE** register allows both edges to cause interrupts. When the corresponding bit in the **GPIO Interrupt Sense (GPIOIS)** register (see page 790) is set to detect edges, setting a bit in the **GPIOIBE** register configures the corresponding pin to detect both rising and falling edges, regardless of the corresponding bit in the **GPIO Interrupt Event (GPIOIEV)** register (see page 792). Clearing a bit configures the pin to be controlled by the **GPIOIEV** register. All bits are cleared by a reset.

GPIO Interrupt Both Edges (GPIOIBE)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (AHB) base: 0x4005.F000

GPIO Port J (AHB) base: 0x4006.0000

GPIO Port K (AHB) base: 0x4006.1000

GPIO Port L (AHB) base: 0x4006.2000

GPIO Port M (AHB) base: 0x4006.3000

GPIO Port N (AHB) base: 0x4006.4000

GPIO Port P (AHB) base: 0x4006.5000

GPIO Port Q (AHB) base: 0x4006.6000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x408

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
------	----------	----	-----------	---

7:0	IBE	RW	0x00	GPIO Interrupt Both Edges
-----	-----	----	------	---------------------------

Value	Description
0	Interrupt generation is controlled by the GPIO Interrupt Event (GPIOIEV) register (see page 792).
1	Both edges on the corresponding pin trigger an interrupt.

Register 5: GPIO Interrupt Event (GPIOIEV), offset 0x40C

The **GPIOIEV** register is the interrupt event register. Setting a bit in the **GPIOIEV** register configures the corresponding pin to detect rising edges or high levels, depending on the corresponding bit value in the **GPIO Interrupt Sense (GPIOIS)** register (see page 790). Clearing a bit configures the pin to detect falling edges or low levels, depending on the corresponding bit value in the **GPIOIS** register. All bits are cleared by a reset.

GPIO Interrupt Event (GPIOIEV)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (AHB) base: 0x4005.F000

GPIO Port J (AHB) base: 0x4006.0000

GPIO Port K (AHB) base: 0x4006.1000

GPIO Port L (AHB) base: 0x4006.2000

GPIO Port M (AHB) base: 0x4006.3000

GPIO Port N (AHB) base: 0x4006.4000

GPIO Port P (AHB) base: 0x4006.5000

GPIO Port Q (AHB) base: 0x4006.6000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x40C

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IEV	RW	0x00	GPIO Interrupt Event
		Value	Description	
		0	A falling edge or a Low level on the corresponding pin triggers an interrupt.	
		1	A rising edge or a High level on the corresponding pin triggers an interrupt.	

Register 6: GPIO Interrupt Mask (GPIOIM), offset 0x410

The **GPIOIM** register is the interrupt mask register. Setting a bit in the **GPIOIM** register allows interrupts that are generated by the corresponding pin to be sent to the interrupt controller on the combined interrupt signal. Clearing a bit prevents an interrupt on the corresponding pin from being sent to the interrupt controller. All bits are cleared by a reset.

GPIO Interrupt Mask (GPIOIM)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (AHB) base: 0x4005.F000

GPIO Port J (AHB) base: 0x4006.0000

GPIO Port K (AHB) base: 0x4006.1000

GPIO Port L (AHB) base: 0x4006.2000

GPIO Port M (AHB) base: 0x4006.3000

GPIO Port N (AHB) base: 0x4006.4000

GPIO Port P (AHB) base: 0x4006.5000

GPIO Port Q (AHB) base: 0x4006.6000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x410

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	DMAIME	RW	0	GPIO uDMA Done Interrupt Mask Enable
		Value	Description	
	0	The μDMA done interrupt is masked and does not cause an interrupt.		
	1	The μDMA done interrupt is not masked and can generate an interrupt to the interrupt controller.		
7:0	IME	RW	0x00	GPIO Interrupt Mask Enable
		Value	Description	
	0	The interrupt from the corresponding pin is masked.		
	1	The interrupt from the corresponding pin is sent to the interrupt controller.		

Register 7: GPIO Raw Interrupt Status (GPIORIS), offset 0x414

The **GPIORIS** register is the raw interrupt status register. A bit in this register is set when an interrupt condition occurs on the corresponding GPIO pin or if a µDMA done interrupt occurs. If the corresponding bit in the **GPIO Interrupt Mask (GPIOIM)** register (see page 793) is set, the interrupt is sent to the interrupt controller. Bits read as zero indicate that corresponding input pins have not initiated an interrupt. For a GPIO level-detect interrupt, the interrupt signal generating the interrupt must be held until serviced. Once the input signal deasserts from the interrupt generating logical sense, the corresponding **RIS** bit in the **GPIORIS** register clears. For a GPIO edge-detect interrupt, the **RIS** bit in the **GPIORIS** register is cleared by writing a ‘1’ to the corresponding bit in the **GPIO Interrupt Clear (GPIOICR)** register. The corresponding **GPIOIM** bit reflects the masked value of the **RIS** bit.

GPIO Raw Interrupt Status (GPIORIS)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	DMARIS	RO	0	GPIO µDMA Done Interrupt Raw Status
	Value	Description		
	0	A µDMA done interrupt has not occurred.		
	1	A µDMA done interrupt has occurred and an interrupt has been triggered and is pending.		

This bit is cleared by writing a 1 to the **DMAIC** bit in the **GPIOICR** register.

Bit/Field	Name	Type	Reset	Description
7:0	RIS	RO	0x00	GPIO Interrupt Raw Status
				Value Description
			0	An interrupt condition has not occurred on the corresponding pin.
			1	An interrupt condition has occurred on the corresponding pin.
				For edge-detect interrupts, this bit is cleared by writing a 1 to the corresponding bit in the GPIOICR register.
				For a GPIO level-detect interrupt, the bit is cleared when the level is deasserted.

Register 8: GPIO Masked Interrupt Status (GPIO MIS), offset 0x418

The **GPIO MIS** register is the masked interrupt status register. If a bit is set in this register, the corresponding interrupt has triggered an interrupt to the interrupt controller. If a bit is clear, either no interrupt has been generated, or the interrupt is masked.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous devices to operate on this microcontroller.

GPIO MIS is the state of the interrupt after masking.

GPIO Masked Interrupt Status (GPIO MIS)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (AHB) base: 0x4005.F000

GPIO Port J (AHB) base: 0x4006.0000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x418

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	DMAMIS	RO	0	GPIO μDMA Done Masked Interrupt Status
	Value	Description		
	0	The μDMA done interrupt is masked or has not occurred.		
	1	An unmasked μDMA done interrupt has occurred.		

This bit is cleared by writing a 1 to the DMAIC bit in the **GPIOICR** register.

Bit/Field	Name	Type	Reset	Description
7:0	MIS	RO	0x00	GPIO Masked Interrupt Status
Value Description				
		0		An interrupt condition on the corresponding pin is masked or has not occurred.
		1		An interrupt condition on the corresponding pin has triggered an interrupt to the interrupt controller.
For edge-detect interrupts, this bit is cleared by writing a 1 to the corresponding bit in the GPIOICR register.				
For a GPIO level-detect interrupt, the bit is cleared when the level is deasserted.				

Register 9: GPIO Interrupt Clear (GPIOICR), offset 0x41C

The **GPIOICR** register is the interrupt clear register. Writing a 1 to the **DMAIC** bit in this register clears the corresponding interrupt bit in the **GPIORIS** and **GPIOVIS** registers. For edge-detect interrupts, writing a 1 to the **IC** bit in the **GPIOICR** register clears the corresponding bit in the **GPIORIS** and **GPIOVIS** registers. If the interrupt is a level-detect, the **IC** bit in this register has no effect. In addition, writing a 0 to any of the bits in the **GPIOICR** register has no effect.

GPIO Interrupt Clear (GPIOICR)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

Offset 0x41C

Type W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	DMAIC	W1C	0	GPIO μDMA Interrupt Clear
		Value	Description	
		0	The μDMA done interrupt is unaffected.	
		1	The μDMA done interrupt is cleared.	
7:0	IC	W1C	0x00	GPIO Interrupt Clear
		Value	Description	
		0	The corresponding interrupt is unaffected.	
		1	The corresponding interrupt is cleared.	

Register 10: GPIO Alternate Function Select (GPIOAFSEL), offset 0x420

Note: Tamper pins enabled in the **Hibernate Tamper IO Control and Status (HIBTPIO)** register override the AFSEL configuration.

The **GPIOAFSEL** register is the mode control select register. If a bit is clear, the pin is used as a GPIO and is controlled by the GPIO registers. Setting a bit in this register configures the corresponding GPIO line to be controlled by an associated peripheral. Several possible peripheral functions are multiplexed on each GPIO. The **GPIO Port Control (GPIOPCTL)** register is used to select one of the possible functions. Table 31-5 on page 2085 details which functions are muxed on each GPIO pin. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in the table below.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0), with the exception of the pins shown in the table below. A Power-On-Reset (**POR**) puts the pins back to their default state.

Table 10-8. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 781.

Note: If the device fails initialization during reset, the hardware toggles the TDO output as an indication of failure. Thus, during board layout, designers should not designate the TDO pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

Caution – It is possible to create a software sequence that prevents the debugger from connecting to the TM4C129XKCZAD microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. As a result, the debugger may be locked out of the part. This issue can be avoided with a software routine that restores JTAG functionality based on an external or software trigger. In the case that the software routine is not implemented and the device is locked out of the part, this issue can be solved by using the TM4C129XKCZAD Flash Programmer “Unlock” feature. Please refer to [LMFLASHPROGRAMMER](#) on the TI web for more information.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the NMI pin (see “Signal Tables” on page 2032 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 799), **GPIO Pull Up Select (GPIOPUR)** register (see page 805), **GPIO Pull-Down Select (GPIOPDR)** register (see page 807), and **GPIO Digital Enable (GPIODEN)** register (see page 810) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 812) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 813) have been set.

When using the I²C module, in addition to setting the **GPIOAFSEL** register bits for the I²C clock and data pins, the data pins should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register (see examples in “Initialization and Configuration” on page 782).

GPIO Alternate Function Select (GPIOAFSEL)

Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	AFSEL	RW	-	GPIO Alternate Function Select
		Value	Description	
		0	The associated pin functions as a GPIO and is controlled by the GPIO registers.	
		1	The associated pin functions as a peripheral signal and is controlled by the alternate hardware function.	
				The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 770.

Register 11: GPIO 2-mA Drive Select (GPIODR2R), offset 0x500

The **GPIODR2R** register is the 2-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV2** bit for a GPIO signal, the corresponding **DRV4** bit in the **GPIODR4R** register and **DRV8** bit in the **GPIODR8R** register are automatically cleared by hardware. By default, all GPIO pins have 2-mA drive.

Note: This register has no effect on port pins PL6 and PL7.

GPIO 2-mA Drive Select (GPIODR2R)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x500

Type RW, reset 0x0000.00FF

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV2	RW	0xFF	Output Pad 2-mA Drive Enable
		Value	Description	
		0	The drive for the corresponding GPIO pin is controlled by the GPIODR4R or GPIODR8R register.	
		1	The corresponding GPIO pin has 2-mA drive.	
		Setting a bit in either the GPIODR4 register or the GPIODR8 register clears the corresponding 2-mA enable bit. The change is effective on the next clock cycle.		

Register 12: GPIO 4-mA Drive Select (GPIODR4R), offset 0x504

The **GPIODR4R** register is the 4-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the **DRV4** bit for a GPIO signal, the corresponding **DRV2** bit in the **GPIODR2R** register and **DRV8** bit in the **GPIODR8R** register are automatically cleared by hardware.

Note: This register has no effect on port pins **PL6** and **PL7**.

GPIO 4-mA Drive Select (GPIODR4R)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port D (AHB) base: 0x4005.B000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (AHB) base: 0x4005.F000

GPIO Port J (AHB) base: 0x4006.0000

GPIO Port K (AHB) base: 0x4006.1000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x504

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV4	RW	0x00	Output Pad 4-mA Drive Enable
				Value Description
			0	The drive for the corresponding GPIO pin is controlled by the GPIODR2R or GPIODR8R register.
			1	The corresponding GPIO pin has 4-mA drive.
				Setting a bit in either the GPIODR2R or the GPIODR8R register clears the corresponding 4-mA enable bit. The change is effective on the next clock cycle.

Register 13: GPIO 8-mA Drive Select (GPIODR8R), offset 0x508

The **GPIODR8R** register is the 8-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads. When setting the `DRV8` bit for a GPIO signal, the corresponding `DRV2` bit in the **GPIODR2R** register and `DRV4` bit in the **GPIODR4R** register are automatically cleared by hardware. The 8-mA setting is also used for high-current operation.

Note: There is no configuration difference between 8-mA and high-current operation. The additional current capacity results from a shift in the V_{OH}/V_{OL} levels. See “Recommended Operating Conditions” on page 2101 for further information.

Note: This register has no effect on port pins PL6 and PL7.

1	The corresponding GPIO pin has 8-mA drive.									

Register 14: GPIO Open Drain Select (GPIOODR), offset 0x50C

The **GPIOODR** register is the open drain control register. Setting a bit in this register enables the open-drain configuration of the corresponding GPIO pad. When open-drain mode is enabled, the corresponding bit should also be set in the **GPIO Digital Enable (GPIODEN)** register (see page 810). Corresponding bits in the drive strength and slew rate control registers (**GPIODR2R**, **GPIODR4R**, **GPIODR8R**, and **GPIOSLR**) can be set to achieve the desired fall times. The GPIO acts as an input if the corresponding bit in the **GPIODIR** register is cleared. If open drain is selected while the GPIO is configured as an input, the GPIO will remain an input and the open-drain selection has no effect until the GPIO is changed to an output.

When using the I²C module, in addition to configuring the data pin to open drain, the **GPIO Alternate Function Select (GPIOAFSEL)** register bits for the I²C clock and data pins should be set (see examples in “Initialization and Configuration” on page 782).

Note: This register has no effect on port pins PL6 and PL7.

GPIO Open Drain Select (GPIOODR)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

		Value	Description	
		0	The corresponding pin is not configured as open drain.	
		1	The corresponding pin is configured as open drain.	

Register 15: GPIO Pull-Up Select (GPIOPUR), offset 0x510

The **GPIOPUR** register is the pull-up control register. When a bit is set, a weak pull-up resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPUR** automatically clears the corresponding bit in the **GPIO Pull-Down Select (GPIOPDR)** register (see page 807). Write access to this register is protected with the **GPIOCR** register. Bits in **GPIOCR** that are cleared prevent writes to the equivalent bit in this register.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0), with the exception of the pins shown in the table below. A Power-On-Reset ($\overline{\text{POR}}$) puts the pins back to their default state.

Table 10-9. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 781.

Note: If the device fails initialization during reset, the hardware toggles the **TDO** output as an indication of failure. Thus, during board layout, designers should not designate the **TDO** pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

Note: The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 2032 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 799), **GPIO Pull Up Select (GPIOPUR)** register (see page 805), **GPIO Pull-Down Select (GPIOPDR)** register (see page 807), and **GPIO Digital Enable (GPIODEN)** register (see page 810) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 812) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 813) have been set.

7:0 PDE RW 0x00 Pad Weak Pull-Down Enable

Value Description

0 The corresponding pin's weak pull-down resistor is disabled.

1 The corresponding pin's weak pull-down resistor is enabled.

Setting a bit in the **GPIOPUR** register clears the corresponding bit in the **GPIOPDR** register. The change is effective on the next clock cycle.

Register 17: GPIO Slew Rate Control Select (GPIOSLR), offset 0x518

The **GPIOSLR** register is the slew rate control register. Slew rate control is only available when using the 8-mA, 10-mA or 12-mA drive strength option. The selection of drive strength is done through the **GPIO Drive Select (GPIODRnR** registers and the **GPIO Peripheral Configuration (GPIOPC)** register.

Note: This register has no effect on port pins PL6 and PL7.

7:0	SRL	RW	0x00	Slew Rate Limit Enable (8-mA, 10-mA and 12-mA drive only)
		Value	Description	
		0	Slew rate control is disabled for the corresponding pin.	
		1	Slew rate control is enabled for the corresponding pin.	

Register 18: GPIO Digital Enable (GPIODEN), offset 0x51C

Note: Pins configured as digital inputs are Schmitt-triggered.

The **GPIODEN** register is the digital enable register. By default, all GPIO signals except those listed below are configured out of reset to be undriven (tristate). Their digital function is disabled; they do not drive a logic value on the pin and they do not allow the pin voltage into the GPIO receiver. To use the pin as a digital input or output (either GPIO or alternate function), the corresponding GPIODEN bit must be set.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0), with the exception of the pins shown in the table below. A Power-On-Reset (**POR**) puts the pins back to their default state.

Table 10-11. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 781.

Note: If the device fails initialization during reset, the hardware toggles the **TDO** output as an indication of failure. Thus, during board layout, designers should not designate the **TDO** pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

Note: The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 2032 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 799), **GPIO Pull Up Select (GPIOPUR)** register (see page 805), **GPIO Pull-Down Select (GPIOPDR)** register (see page 807), and **GPIO Digital Enable (GPIODEN)** register (see page 810) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 812) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 813) have been set.

Offset 0x51C

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Value Description

- 0 The digital functions for the corresponding pin are disabled.

- 1 The digital functions for the corresponding pin are enabled.

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 770.

Register 19: GPIO Lock (GPIOLOCK), offset 0x520

The **GPIOLOCK** register enables write access to the **GPIOCR** register (see page 813). Writing 0x4C4F.434B to the **GPIOLOCK** register unlocks the **GPIOCR** register. Writing any other value to the **GPIOLOCK** register re-enables the locked state. Reading the **GPIOLOCK** register returns the lock status rather than the 32-bit value that was previously written. Therefore, when write accesses are disabled, or locked, reading the **GPIOLOCK** register returns 0x0000.0001. When write accesses are enabled, or unlocked, reading the **GPIOLOCK** register returns 0x0000.0000.

Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0 LOCK RW 0x0000.0001 GPIO Lock

A write of the value 0x4C4F.434B unlocks the **GPIOCR** register for write access. A write of any other value or a write to the **GPIOCR** register reapplies the lock, preventing any register updates.

A read of this register returns the following values:

Value Description

0x1 The **GPIOCR** register is locked and may not be modified.

0x0 The **GPIOCR** register is unlocked and may be modified.

Register 20: GPIO Commit (GPIOCR), offset 0x524

The **GPIOCR** register is the commit register. The value of the **GPIOCR** register determines which bits of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, and **GPIODEN** registers are committed when a write to these registers is performed. If a bit in the **GPIOCR** register is cleared, the data being written to the corresponding bit in the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** registers cannot be committed and retains its previous value. If a bit in the **GPIOCR** register is set, the data being written to the corresponding bit of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** registers is committed to the register and reflects the new value.

The contents of the **GPIOCR** register can only be modified if the status in the **GPIOLOCK** register is unlocked. Writes to the **GPIOCR** register are ignored if the status in the **GPIOLOCK** register is locked.

Important: This register is designed to prevent accidental programming of the registers that control connectivity to the NMI and JTAG/SWD debug hardware. By initializing the bits of the **GPIOCR** register to 0 for the NMI and JTAG/SWD pins (see “Signal Tables” on page 2032 for pin numbers), the NMI and JTAG/SWD debug port can only be converted to GPIOs through a deliberate set of writes to the **GPIOLOCK**, **GPIOCR**, and the corresponding registers.

Because this protection is currently only implemented on the NMI and JTAG/SWD pins (see “Signal Tables” on page 2032 for pin numbers), all of the other bits in the **GPIOCR** registers cannot be written with 0x0. These bits are hardwired to 0x1, ensuring that it is always possible to commit new values to the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** register bits of these other pins.

7:0	CR	-	-	GPIO Commit
				Value Description
			0	The corresponding GPIOAFSEL , GPIOPUR , GPIOPDR , or GPIODEN bits cannot be written.
			1	The corresponding GPIOAFSEL , GPIOPUR , GPIOPDR , or GPIODEN bits can be written.
Note: The default register type for the GPIOCR register is RO for all GPIO pins with the exception of the NMI pin and the four JTAG/SWD pins (see “Signal Tables” on page 2032 for pin numbers). These six pins are the only GPIOs that are protected by the GPIOCR register. Because of this, the register type for the corresponding GPIO Ports is RW.				
The default reset value for the GPIOCR register is 0x0000.00FF for all GPIO pins, with the exception of the NMI pin and the four JTAG/SWD pins (see “Signal Tables” on page 2032 for pin numbers). To ensure that the JTAG and NMI pins are not accidentally programmed as GPIO pins, these pins default to non-committable. Because of this, the default reset value of GPIOCR changes for the corresponding ports.				

Register 21: GPIO Analog Mode Select (GPIOAMSEL), offset 0x528

Important: This register is only valid for ports and pins that can be used as ADC AIN_x inputs.

If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be set to disable the analog isolation circuit.

The **GPIOAMSEL** register controls isolation circuits to the analog side of a unified I/O pad. Because the GPIOs may be driven by a 3.3-V source and affect analog operation, analog circuitry requires isolation from the pins when they are not used in their analog function.

Each bit of this register controls the isolation circuitry for the corresponding GPIO signal. For information on which GPIO pins can be used for ADC functions, refer to Table 31-5 on page 2085.

GPIO Analog Mode Select (GPIOAMSEL)

GPIO Port A (AHB) base: 0x4005.8000

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	GPIOAMSEL	RW	0x00	GPIO Analog Mode Select
	Value	Description		
	0	The analog function of the pin is disabled, the isolation is enabled, and the pin is capable of digital functions as specified by the other GPIO configuration registers.		
	1	The analog function of the pin is enabled, the isolation is disabled, and the pin is capable of analog functions.		

Note: This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad.

The reset state of this register is 0 for all signals.

Register 22: GPIO Port Control (GPIOPCTL), offset 0x52C

The **GPIOPCTL** register is used in conjunction with the **GPIOAFSEL** register and selects the specific peripheral signal for each GPIO pin when using the alternate function mode. Most bits in the **GPIOAFSEL** register are cleared on reset, therefore most GPIO pins are configured as GPIOs by default. When a bit is set in the **GPIOAFSEL** register, the corresponding GPIO signal is controlled by an associated peripheral. The **GPIOPCTL** register selects one out of a set of peripheral functions for each GPIO, providing additional flexibility in signal definition. For information on the defined encodings for the bit fields in this register, refer to Table 31-5 on page 2085. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in the table below.

Note: If a particular input signal to a peripheral is assigned to two different GPIO port pins, the signal is assigned to the port with the lowest letter and the assignment to the higher letter port is ignored. If a particular output signal from a peripheral is assigned to two different GPIO port pins, the signal will output to both pins. Assigning an output signal from a peripheral to two different GPIO pins is not recommended.

Important: All GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0), with the exception of the pins shown in the table below. A Power-On-Reset (**POR**) puts the pins back to their default state.

Table 10-12. GPIO Pins With Non-Zero Reset Values

GPIO Pins	Default State	GPIOAFSEL	GPIODEN	GPIOPDR	GPIOPUR	GPIOPCTL
PC[3:0]	JTAG/SWD	1	1	0	1	0x1

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the NMI signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 781.

Note: If the device fails initialization during reset, the hardware toggles the TDO output as an indication of failure. Thus, during board layout, designers should not designate the TDO pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

GPIO Port Control (GPIOPCTL)

GPIO Port A (AHB) base: 0x4005.8000
 GPIO Port B (AHB) base: 0x4005.9000
 GPIO Port C (AHB) base: 0x4005.A000

Register 23: GPIO ADC Control (GPIOADCCTL), offset 0x530

This register is used to configure a GPIO pin as a source for the ADC trigger.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous devices to operate on this microcontroller.

GPIO ADC Control (GPIOADCCTL)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port Q (AHB) base: 0x4006.6000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x538

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	SUM	RW	0	Summary Interrupt
	Value	Description		
	0	All port pin interrupts are OR'ed together to produce a summary interrupt.		
	1	Each pin has its own interrupt vector.		
Note: The OR'ed summary interrupt occurs on bit 0 of the GPIORIS register. For summary interrupt mode, software should set the GPIOIM register to 0xFF and mask the port pin interrupts 1 through 7 in the Interrupt Clear Enable (DISn) register (see “NVIC Register Descriptions” on page 163). When servicing this interrupt, write a 1 to the corresponding bit in the UNPENDn register to clear the pending interrupt in the NVIC and clear the GPIORIS register pin interrupt bits by setting the IC field of the GPIOICR register to 0xFF.				

Register 26: GPIO 12-mA Drive Select (GPIODR12R), offset 0x53C

The **GPIODR12R** register is the 12-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads.

Note: This register has no effect on port pins PL6 and PL7 or PM[7 : 4].

GPIO 12-mA Drive Select (GPIODR12R)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port B (AHB) base: 0x4005.9000

GPIO Port C (AHB) base: 0x4005.A000

GPIO Port E (AHB) base: 0x4005.C000

GPIO Port F (AHB) base: 0x4005.D000

GPIO Port G (AHB) base: 0x4005.E000

GPIO Port H (AHB) base: 0x4005.F000

GPIO Port J (AHB) base: 0x4006.0000

GPIO Port K (AHB) base: 0x4006.1000

GPIO Port L (AHB) base: 0x4006.2000

GPIO Port M (AHB) base: 0x4006.3000

GPIO Port N (AHB) base: 0x4006.4000

GPIO Port P (AHB) base: 0x4006.5000

GPIO Port Q (AHB) base: 0x4006.6000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0x53C

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV12	RW	0x00	Output Pad 12-mA Drive Enable
	Value	Description		
0	The drive for the corresponding GPIO pin is controlled by the GPIODR2R , GPIODR4R , and/or the GPIODR8R register.			
1	The corresponding GPIO pin has 12-mA drive. This encoding is only valid if the GPIOPP EDE bit is set and the appropriate GPIOPC EDM bit field is programmed to 0x3.			

Note: Please refer to Table 10-3 on page 782 for information on how to configure the drive strength.

Changes in the **GPIODR2R**, the **GPIODR4R** register and/or the **GPIODR8R** registers to configure 12 mA are effective on the next clock cycle.

Register 27: GPIO Wake Pin Enable (GPIOWAKEPEN), offset 0x540

This register is used to configure K[7:4] as a wake enable source for the hibernation module. The wake level must be programmed in the **GPIOWAKELVL** register at offset 0x544. In order for this register configuration to become implemented, the WUUNLK bit needs to be set in the **HIBIO** register at offset 0x02C in the hibernation module.

Note: This register is only available on Port K.

GPIO Wake Pin Enable (GPIOWAKEPEN)

GPIO Port A (AHB) base: 0x4005.8000

GPIO Port P (AHB) base: 0x4006.5000

GPIO Port Q (AHB) base: 0x4006.6000

GPIO Port R (AHB) base: 0x4006.7000

GPIO Port S (AHB) base: 0x4006.8000

GPIO Port T (AHB) base: 0x4006.9000

Offset 0xFC0

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	EDE	RO	0x1	Extended Drive Enable This bit specifies whether the extended drive capabilities are provided. Extended drive is configured by the EDM bits in the GPIOPC register.
Value Description				
0 No Extended Drive Capability provided.				
1 Extended Drive Capability provided.				

Register 31: GPIO Peripheral Configuration (GPIOPC), offset 0xFC4

This **GPIOPC** register controls the extended drive modes of the GPIO and must be configured before the **GPIODRnR** registers in order for extended drive mode to take effect. When the **EDE** bit in **GPIOPP** register is set and the **EDMn** bit field is non-zero, the **GPIODRnR** registers do not drive their default value, but instead output an incremental drive strength, which has an additive effect. This allows for more drive strength possibilities. When the **EDE** bit is set and the **EDMn** bit field is non-zero, the 2 mA driver is always enabled. Any bits enabled in the **GPIODR4R** register will add an additional 2 mA; any bits set in the **GPIODR8R** add an extra 4 mA of drive. The **GPIODR12R** register is only valid when the **EDMn** value is 0x3. For this encoding, setting a bit in the **GPIODR12R** register adds 4 mA of drive to the already existing 8 mA, for a 12 mA drive strength. Table 10-3 on page 782 shows the drive capability options. If **EDMn** is 0x00, then the **GPIODR2R**, **GPIODR4R**, and **GPIODR8R** function as stated in their default register description.

Table 10-13. GPIO Drive Strength Options

EDE (GPIOPP)	EDMn (GPIOPC)	GPIODR12R (+4mA)	GPIODR8R (+4mA)	GPIODR4R (+2mA)	GPIODR2R (2mA)	Drive (mA)
X	0x0	N/A	0	0	1	2

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:14	EDM7	RW	0	Extended Drive Mode Bit 7 Same encoding as EDM0, but applies to bit 7 of GPIO port.
13:12	EDM6	RW	0	Extended Drive Mode Bit 6 Same encoding as EDM0, but applies to bit 6 of GPIO port.
11:10	EDM5	RW	0	Extended Drive Mode Bit 5 Same encoding as EDM0, but applies to bit 5 of GPIO port.
9:8	EDM4	RW	0	Extended Drive Mode Bit 4 Same encoding as EDM0, but applies to bit 4 of GPIO port.
7:6	EDM3	RW	0	Extended Drive Mode Bit 3 Same encoding as EDM0, but applies to bit 3 of GPIO port.
5:4	EDM2	RW	0	Extended Drive Mode Bit 2 Same encoding as EDM0, but applies to bit 2 of GPIO port.
3:2	EDM1	RW	0	Extended Drive Mode Bit 1 Same encoding as EDM0, but applies to bit 1 of GPIO port.

Bit/Field	Name	Type	Reset	Description
1:0	EDM0	RW	0	<p>Extended Drive Mode Bit 0</p> <p>This field controls extended drive modes of bit 0 of the GPIO port.</p> <p>Note that depending on the encoding used the GPIO drive strength control registers may change their decoding. Moreover, the write one, clear other register behavior may be disabled.</p>
Value Description				
0x0 Drive values of 2, 4 and 8 mA are maintained. GPIO n Drive Select (GPIODRnR) registers function as normal.				
0x1 An additional 6 mA option is provided. Write one, clear other behavior of GPIODDRnR registers is disabled. A 2 mA driver is always enabled; setting the corresponding GPIODR4R register bit adds 2 mA and setting the corresponding GPIODR8R register bit adds an additional 4 mA.				
0x2 reserved				
0x3 Additional drive strength options of 6, 10, and 12 mA are provided. The write one, clear other behavior of GPIODDRnR registers is disabled. A 2 mA driver is always enabled; setting the corresponding GPIODR4R register bit adds 2 mA and setting the corresponding GPIODR8R of GPIODR12R register bit adds an additional 4 mA.				

Register 32: GPIO Peripheral Identification 4 (GPIOPeriphID4), offset 0xFD0

The **GPIOPeriphID4**, **GPIOPeriphID5**, **GPIOPeriphID6**, and **GPIOPeriphID7** registers can conceptually be treated as one 32-bit register; each register contains eight bits of the 32-bit register, used by software to identify the peripheral.

11 External Peripheral Interface (EPI)

The External Peripheral Interface is a high-speed parallel bus for external peripherals or memory. It has several modes of operation to interface gluelessly to many types of external devices. The External Peripheral Interface is similar to a standard microprocessor address/data bus, except that it must typically be connected to just one type of external device. Enhanced capabilities include μ DMA support, clocking control and support for external FIFO buffers.

The EPI has the following features:

- 8/16/32-bit dedicated parallel bus for external peripherals and memory
- Memory interface supports contiguous memory access independent of data bus width, thus enabling code execution directly from SDRAM, SRAM and Flash memory
- Blocking and non-blocking reads
- Separates processor from timing details through use of an internal write FIFO
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for read and write
 - Read channel request asserted by programmable levels on the internal Non-Blocking Read FIFO (NBRFIFO)
 - Write channel request asserted by empty on the internal Write FIFO (WFIFO)

The EPI supports three primary functional modes: Synchronous Dynamic Random Access Memory (SDRAM) mode, Traditional Host-Bus mode, and General-Purpose mode. The EPI module also provides custom GPIOs; however, unlike regular GPIOs, the EPI module uses a FIFO in the same way as a communication mechanism and is speed-controlled using clocking.

- Synchronous Dynamic Random Access Memory (SDRAM) mode
 - Supports x16 (single data rate) SDRAM at up to 60 MHz
 - Supports low-cost SDRAMs up to 64 MB (512 megabits)
 - Includes automatic refresh and access to all banks/rows
 - Includes a Sleep/Standy mode to keep contents active with minimal power draw
 - Multiplexed address/data interface for reduced pin count
- Host-Bus mode
 - Traditional x8 and x16 MCU bus interface capabilities
 - Similar device compatibility options as PIC, ATmega, 8051, and others
 - Access to SRAM, NOR Flash memory, and other devices, with up to 1 MB of addressing in non-multiplexed mode and 256 MB in multiplexed mode (512 MB in Host-Bus 16 mode with no byte selects)

- Support for up to 512 Mb PSRAM in quad chip select mode, with dedicated configuration register read and write enable.
- Support of both muxed and de-muxed address and data
- Access to a range of devices supporting the non-address FIFO x8 and x16 interface variant, with support for external FIFO (XFIFO) EMPTY and FULL signals
- Speed controlled, with read and write data wait-state counters
- Support for read/write burst mode to Host Bus
- Multiple chip select modes including single, dual, and quad chip selects, with and without ALE
- External iRDY signal provided for stall capability of reads and writes
 - Manual chip-enable (or use extra address pins)
- General-Purpose mode
 - Wide parallel interfaces for fast communications with CPLDs and FPGAs
 - Data widths up to 32 bits
 - Data rates up to 150 MB/second
 - Optional "address" sizes from 4 bits to 20 bits
 - Optional clock output, read/write strobes, framing (with counter-based size), and clock-enable input
- General parallel GPIO
 - 1 to 32 bits, FIFOed with speed control
 - Useful for custom peripherals or for digital data acquisition and actuator controls

11.1 EPI Block Diagram

Figure 11-1 on page 846 provides a block diagram of a TM4C129XKCZAD EPI module.

Figure 11-1. EPI Block Diagram

11.2 Signal Description

The following table lists the external signals of the EPI controller and describes the function of each. The EPI controller signals are alternate functions for GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the EPI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the EPI controller function. The number in parentheses is the encoding that must be programmed into the PMCn field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the EPI signals to the specified GPIO port pins. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769.

Table 11-1. External Peripheral Interface Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
EPI0S0	P4 J1	PH0 (15) PK0 (15)	I/O	TTL	EPI module 0 signal 0.
EPI0S1	R2 J2	PH1 (15) PK1 (15)	I/O	TTL	EPI module 0 signal 1.

EPI0S23	M4	PQ3 (15)	I/O	TTL	EPI module 0 signal 23.
EPI0S24	W16	PK7 (15)	I/O	TTL	EPI module 0 signal 24.
EPI0S25	V16	PK6 (15)	I/O	TTL	EPI module 0 signal 25.
EPI0S26	H18	PL4 (15)	I/O	TTL	EPI module 0 signal 26.
EPI0S27	A17	PB2 (15)	I/O	TTL	EPI module 0 signal 27.
EPI0S28	B17	PB3 (15)	I/O	TTL	EPI module 0 signal 28.
EPI0S29	A11 B13	PN2 (15) PP2 (15)	I/O	TTL	EPI module 0 signal 29.
EPI0S30	B10 C12	PN3 (15) PP3 (15)	I/O	TTL	EPI module 0 signal 30.
EPI0S31	V17	PK5 (15)	I/O	TTL	EPI module 0 signal 31.
EPI0S32	U19	PK4 (15)	I/O	TTL	EPI module 0 signal 32.
EPI0S33	G19	PL5 (15)	I/O	TTL	EPI module 0 signal 33.
EPI0S34	A10	PN4 (15)	I/O	TTL	EPI module 0 signal 34.
EPI0S35	B9	PN5 (15)	I/O	TTL	EPI module 0 signal 35.

11.3 Functional Description

The EPI controller provides a glueless, programmable interface to a variety of common external peripherals such as SDRAM x 16, Host Bus x8 and x16 devices, RAM, NOR Flash memory, CPLDs and FPGAs. In addition, the EPI controller provides custom GPIO that can use a FIFO with speed control by using either the internal write FIFO (WFIFO) or the non-blocking read FIFO (NBRFIFO). The WFIFO can hold 4 words of data that are written to the external interface at the rate controlled by the **EPI Main Baud Rate (EPIBAUD)** registers. The NBRFIFO can hold 8 words of data and samples at the rate controlled by the **EPIBAUD** register. The EPI controller provides predictable operation and thus has an advantage over regular GPIO which has more variable timing due to on-chip bus arbitration and delays across bus bridges. Blocking reads stall the CPU until the transaction completes. Non-blocking reads are performed in the background and allow the processor

to continue operation. In addition, write data can also be stored in the WFIFO to allow multiple writes with no stalls.

Note: Both the WTAV bit field in the **EPIWFIFOCNT** register and the WBUSY bit in the **EPISTAT** register must be polled to determine if there is a current write transaction from the WFIFO. If both of these bits are clear, then a new bus access may begin.

Main read and write operations can be performed in subsets of the range 0x6000.0000 to 0xDFFF.FFFF. A read from an address mapped location uses the offset and size to control the address and size of the external operation. When performing a multi-value load, the read is done as a burst (when available) to maximize performance. A write to an address mapped location uses the offset and size to control the address and size of the external operation. When performing a multi-value store, the write is done as a burst (when available) to maximize performance.

11.3.1 Master Access to EPI

The following lists the Bus Masters which have access to the EPI:

- CPU
- μDMA
- LCD

11.3.2 Non-Blocking Reads

The EPI Controller supports a special kind of read called a non-blocking read, also referred to as a posted read. Where a normal read stalls the processor or μDMA until the data is returned, a non-blocking read is performed in the background.

A non-blocking read is configured by writing the start address into a **EPIRADDRn** register, the size per transaction into a **EPIRSIZEn** register, and then the count of operations into a **EIPRPSTDn** register. After each read is completed, the result is written into the NBRFIFO and the **EPIRADDRn** register is incremented by the size (1, 2, or 4). The three most significant bits of **EPIRADDRn** register are only relevant in the Host Bus multi-chip select mode when they are used to enable the different chip selects.

If the NBRFIFO is filled, then the reads pause until space is made available. The NBRFIFO can be configured to interrupt the processor or trigger the μDMA based on fullness using the **EPIFOLVL** register. By using the trigger/interrupt method, the μDMA (or processor) can keep space available in the NBRFIFO and allow the reads to continue unimpeded.

When performing non-blocking reads, the SDRAM controller issues two additional read transactions after the burst request is terminated. The data for these additional transfers is discarded. This situation is transparent to the user other than the additional EPI bus activity and can safely be ignored.

Two non-blocking read register sets are available to allow sequencing and ping-pong use. When one completes, the other then activates. So, for example, if 20 words are to be read from 0x100 and 10 words from 0x200, the **EIPRPSTD0** register can be set up with the read from 0x100 (with a count of 20), and the **EIPRPSTD1** register can be set up with the read from 0x200 (with a count of 10). When **EIPRPSTD0** finishes (count goes to 0), the **EIPRPSTD1** register then starts its operation. The NBRFIFO has then passed 30 values. When used with the μDMA, it may transfer 30 values (simple sequence), or the primary/alternate model may be used to handle the first 20 in one way and the second 10 in another. It is also possible to reload the **EIPRPSTD0** register when it is finished (and the **EIPRPSTD1** register is active); thereby, keeping the interface constantly busy.

To cancel a non-blocking read, the **EPIRPSTDn** register is cleared. Care must be taken, however if the register set was active to drain away any values read into the NBRIFO and ensure that any read in progress is allowed to complete.

To ensure that the cancel is complete, the following algorithm is used (using the **EPIRPSTD0** register for example):

```
EPIRPSTD0 = 0;
while ((EPISTAT & 0x11) == 0x10)
; // we are active and busy
// if here, then other one is active or interface no longer busy
cnt = (EPIRADDR0 – original_address) / EPIRSIZE0; // count of values read
cnt -= values_read_so_far;
// cnt is now number left in FIFO
while (cnt--)
value = EPIREADFIFO; // drain
```

The above algorithm can be optimized in code; however, the important point is to wait for the cancel to complete because the external interface could have been in the process of reading a value when the cancel came in, and it must be allowed to complete.

11.3.3 DMA Operation

The μDMA can be used to achieve maximum transfer rates on the EPI through the NBRIFO and the WFIFO. The μDMA has one channel for write and one for read. For writes, the **EPI DMA Transmit Count (EPIDMATXCNT)** register is programmed with the total number of transfers by the μDMA. An equivalent value is programmed into the **DMA Channel Control Word (DMACHCTL)** register of the uDMA at offset 0x008. A μDMA request is asserted by the EPI WRFIFO when the TXCNT value of the **EPIDMATXCNT** register is greater than zero and the WTAV bit field of the **EPIWFIFOCNT** register is less than the programmed threshold trigger, WRFIFO, of the **EPIFIFOLVL** register. The write channel continues to write data until the TXCNT value in the **EPIDMATXCNT** register is zero.

Note: When the WRFIFO bit in the **EPIFIFOLVL** register is set to 0x4 and the application bursts four words to an empty FIFO, the WRFIFO trigger may or may not deassert depending on if all four words were written to the WRFIFO or if the first word was passed immediately to the function requiring it. Thus, the application may not see the WRRIS bit in the **EPIRIS** register clear on a burst of four words.

The non-blocking read channel copies values from the NBRIFO when the NBRIFO is at the level specified by the **EPIFIFOLVL** register. For non-blocking reads, the start address, the size per transaction, and the count of elements must be programmed in the μDMA. Note that both non-blocking read register sets can be used, and they fill the NBRIFO such that one runs to completion, then the next one starts (they do not interleave). Using the NBRIFO provides the best possible transfer rate.

For blocking reads, the μDMA software channel (or another unused channel) is used for memory-to-memory transfers (or memory to peripheral, where some other peripheral is used). In this situation, the μDMA stalls until the read is complete and is not able to service another channel until the read is done. As a result, the arbitration size should normally be programmed to one access at a time. The μDMA controller can also transfer from and to the NBRIFO and the WFIFO using the μDMA software channel in memory mode, however, the μDMA is stalled once the NBRIFO is

empty or the WFIFO is full. Note that when the μ DMA controller is stalled, the core continues operation. See “Micro Direct Memory Access (μ DMA)” on page 705 for more information on configuring the μ DMA.

The size of the FIFOs must be taken into consideration when configuring the μ DMA to transfer data to and from the EPI. The arbitration size should be 4 or less when writing to EPI address space and 8 or less when reading from EPI address space.

11.4 Initialization and Configuration

To enable and initialize the EPI controller, the following steps are necessary:

1. Enable the EPI module using the **RCGCEPI** register. See page 402.
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register. See page 398. To find out which GPIO port to enable, refer to “Signal Description” on page 846.
3. Set the GPIO AFSEL bits for the appropriate pins. See page 799. To determine which GPIOs to configure, see Table 31-4 on page 2068.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected. See page 801 and page 809.
5. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the EPI signals to the appropriate pins. See page 816 and Table 31-5 on page 2085.
6. Select the mode for the EPI block to SDRAM, HB8, HB16, or general parallel use, using the **MODE** field in the **EPI Configuration (EPICFG)** register. Set the mode-specific details (if needed) using the appropriate mode configuration **EPI Host Bus Configuration (EPIHBNCFGn)** registers for the desired chip-select configuration. Set the **EPI Main Baud Rate (EPIBAUD)** and **EPI Main Baud Rate 2 (EPIBAUD2)** register if the baud rate must be slower than the system clock rate.
7. Configure the address mapping using the **EPI Address Map (EPIADDRMAP)** register. The selected start address and range is dependent on the type of external device and maximum address (as appropriate). For example, for a 512-megabit SDRAM, program the **ERADR** field to 0x1 for address 0x6000.0000 or 0x2 for address 0x8000.0000; and program the **ERSZ** field to 0x3 for 256 MB. If using General-Purpose mode and no address at all, program the **EPADR** field to 0x1 for address 0xA000.0000 or 0x2 for address 0xC000.0000; and program the **EPSZ** field to 0x0 for 256 bytes.
8. To read or write directly, use the mapped address area (configured with the **EPIADDRMAP** register). Up to 4 or 5 writes can be performed at once without blocking. Each read is blocked until the value is retrieved.
9. To perform a non-blocking read, see “Non-Blocking Reads” on page 848.

Note: The application should not attempt to access externally until eight system clock cycles after the EPI has been fully configured.

Note: Once a **MODE** field has been programmed in the **EPICFG** register, the application should reset all configuration registers before re-programming to a new **MODE** value.

The following sub-sections describe the initialization and configuration for each of the modes of operation. Care must be taken to initialize everything properly to ensure correct operation. Control of the GPIO states is also important, as changes may cause the external device to interpret pin

states as actions or commands (see “Register Descriptions” on page 787). Normally, a pull-up or pull-down is needed on the board to at least control the chip-select or chip-enable as the TM4C129XKCZAD GPIOs come out of reset in tri-state.

11.4.1 EPI Interface Options

There are a variety of memories and peripherals that can interface to the EPI module. Table 11-2 on page 851 shows the various configurations with their maximum performance.

Table 11-2. EPI Interface Options

Interface	Maximum Frequency
Single SDRAM	60 MHz
Single SRAM	60 MHz
Single PSRAM without iRDY signal use	55 MHz
Single PSRAM with iRDY signal use	52 MHz
FPGAs, CPLDs, etc using General Purpose Mode	60 MHz
Memory configurations with 2 chip selects	40 MHz
Memory configurations with 4 chip selects	20 MHz

11.4.2 SDRAM Mode

When activating the SDRAM mode, it is important to consider a few points:

1. Generally, it takes over 100 µs from when the mode is activated to when the first operation is allowed. The SDRAM controller begins the SDRAM initialization sequence as soon as the mode is selected and enabled via the **EPICFG** register. It is important that the GPIOs are properly configured before the SDRAM mode is enabled, as the EPI controller is relying on the GPIO block's ability to drive the pins immediately. As part of the initialization sequence, the LOAD MODE REGISTER command is automatically sent to the SDRAM with a value of 0x27, which sets a CAS latency of 2 and a full page burst length.
2. The **INITSEQ** bit in the **EPI Status (EPISTAT)** register can be checked to determine when the initialization sequence is complete.
3. When using a frequency range and/or refresh value other than the default value, it is important to configure the **FREQ** and **RFSH** fields in the **EPI SDRAM Configuration (EPISDRAMCFG)** register shortly after activating the mode. After the 100-µs startup time, the EPI block must be configured properly to keep the SDRAM contents stable.
4. The **SLEEP** bit in the **EPISDRAMCFG** register may be configured to put the SDRAM into a low-power self-refreshing state. It is important to note that the SDRAM mode must not be disabled once enabled, or else the SDRAM is no longer clocked and the contents are lost.
5. Before entering SLEEP mode, make sure all non-blocking reads and normal reads and writes have completed. If the system is running at 30 to 50 MHz, wait 2 EPI clocks after clearing the **SLEEP** bit before executing non-blocking reads, or normal reads and writes. If the system is configured to greater than 50 MHz, wait 5 EPI clocks before read and write transactions. For all other configurations, wait 1 EPI clock.

The **SIZE** field of the **EPISDRAMCFG** register must be configured correctly based on the amount of SDRAM in the system.

The FREQ field must be configured according to the value that represents the range being used. Based on the range selected, the number of external clocks used between certain operations (for example, PRECHARGE or ACTIVATE) is determined. If a higher frequency is given than is used, then the only downside is that the peripheral is slower (uses more cycles for these delays). If a lower frequency is given, incorrect operation occurs.

See “External Peripheral Interface (EPI)” on page 2127 for timing details for the SDRAM mode.

11.4.2.1 External Signal Connections

Table 11-3 on page 852 defines how EPI module signals should be connected to SDRAMs. The table applies when using a x16 SDRAM up to 512 megabits. Note that the EPI signals must use 8-mA drive when interfacing to SDRAM, see page 803. Any unused EPI controller signals can be used as GPIOs or another alternate function.

Table 11-3. EPI SDRAM x16 Signal Connections

EPI Signal	SDRAM Signal ^a	
EPI0S0	A0	D0
EPI0S1	A1	D1
EPI0S2	A2	D2
EPI0S3	A3	D3
EPI0S4	A4	D4
EPI0S5	A5	D5
EPI0S6	A6	D6
EPI0S7	A7	D7
EPI0S8	A8	D8
EPI0S9	A9	D9
EPI0S10	A10	D10
EPI0S11	A11	D11
EPI0S12	A12 ^b	D12
EPI0S13	BA0	D13
EPI0S14	BA1	D14
EPI0S15	D15	
EPI0S16	DQML	
EPI0S17	DQMH	
EPI0S18	CASn	
EPI0S19	RASn	
EPI0S20-EPI0S27	not used	
EPI0S28	WE _n	
EPI0S29	CS _n	
EPI0S30	CKE	
EPI0S31	CLK	

a. If two signals are listed, connect the EPI signal to both pins.

b. Only for 256/512 megabit SDRAMs.

11.4.2.2 Refresh Configuration

The refresh count is based on the external clock speed and the number of rows per bank as well as the refresh period. The RFSH field represents how many external clock cycles remain before an AUTO-REFRESH is required. The normal formula is:

$$\text{RFSH} = (\text{t}_{\text{Refresh_us}} / \text{number_rows}) / \text{ext_clock_period}$$

A refresh period is normally 64 ms, or 64000 µs. The number of rows is normally 4096 or 8192. The ext_clock_period is a value expressed in µsec and is derived by dividing 1000 by the clock speed expressed in MHz. So, 50 MHz is $1000/50=20$ ns, or 0.02 µs. A typical SDRAM is 4096 rows per bank if the system clock is running at 50 MHz with an **EPIBAUD** register value of 0:

$$\text{RFSH} = (64000/4096) / 0.02 = 15.625 \mu\text{s} / 0.02 \mu\text{s} = 781.25$$

The default value in the RFSH field is 750 decimal or 0x2EE to allow for a margin of safety and providing 15 µs per refresh. It is important to note that this number should always be smaller or equal to what is required by the above equation. For example, if running the external clock at 25 MHz (40 ns per clock period), 390 is the highest number that may be used. Note that the external clock may be 25 MHz when the system clock is 25 MHz or when the system clock is 50 MHz and configuring the COUNT0 field in the **EPIBAUD** register to 1 (divide by 2).

If a number larger than allowed is used, the SDRAM is not refreshed often enough, and data is lost.

11.4.2.3 Bus Interface Speed

The EPI Controller SDRAM interface can operate up to 60 MHz. The COUNT0 field in the **EPIBAUD** register configures the speed of the EPI clock. For system clock (SysClk) speeds up to 60 MHz, the COUNT0 field can be 0x0000, and the SDRAM interface can run at the same speed as SysClk. However, if SysClk is running at higher speeds, the bus interface can run only as fast as half speed, and the COUNT0 field must be configured to at least 0x0001.

11.4.2.4 Non-Blocking Read Cycle

Figure 11-2 on page 854 shows a non-blocking read cycle of n halfwords; n can be any number greater than or equal to 1. The cycle begins with the Activate command and the row address on the EPIOS[15:0] signals. With the programmed CAS latency of 2, the Read command with the column address on the EPIOS[15:0] signals follows after 2 clock cycles. Following one more NOP cycle, data is read in on the EPIOS[15:0] signals on every rising clock edge. The Burst Terminate command is issued during the cycle when the next-to-last halfword is read in. The DQMH and DQML signals are deasserted after the last halfword of data is received; the CSn signal deasserts on the following clock cycle, signaling the end of the read cycle. At least one clock period of inactivity separates any two SDRAM cycles.

Figure 11-2. SDRAM Non-Blocking Read Cycle**11.4.2.5 Normal Read Cycle**

Figure 11-3 on page 854 shows a normal read cycle of n halfwords; n can be 1 or 2. The cycle begins with the Activate command and the row address on the EPI0S[15:0] signals. With the programmed CAS latency of 2, the Read command with the column address on the EPI0S[15:0] signals follows after 2 clock cycles. Following one more NOP cycle, data is read in on the EPI0S[15:0] signals on every rising clock edge. The DQMH, DQML, and CSn signals are deasserted after the last halfword of data is received, signaling the end of the cycle. At least one clock period of inactivity separates any two SDRAM cycles.

Figure 11-3. SDRAM Normal Read Cycle

11.4.2.6 Write Cycle

Figure 11-4 on page 855 shows a write cycle of n halfwords; n can be any number greater than or equal to 1. The cycle begins with the Activate command and the row address on the EPIOS[15:0] signals. With the programmed CAS latency of 2, the Write command with the column address on the EPIOS[15:0] signals follows after 2 clock cycles. When writing to SDRAMs, the Write command is presented with the first halfword of data. Because the address lines and the data lines are multiplexed, the column address is modified to be (programmed address -1). During the Write command, the DQMH and DQML signals are high, so no data is written to the SDRAM. On the next clock, the DQMH and DQML signals are asserted, and the data associated with the programmed address is written. The Burst Terminate command occurs during the clock cycle following the write of the last halfword of data. The WEn, DQMH, DQML, and CSn signals are deasserted after the last halfword of data is received, signaling the end of the access. At least one clock period of inactivity separates any two SDRAM cycles.

Figure 11-4. SDRAM Write Cycle

11.4.3 Host Bus Mode

Host Bus supports the traditional 8-bit and 16-bit interfaces popularized by the 8051 devices and SRAM devices, as well as PSRAM and NOR Flash memory. This interface is asynchronous and uses strobe pins to control activity. Addressable memory can be doubled using Host Bus-16 mode as it performs half-word accesses. The EPIOS0 is the LSB of the address and is equivalent to the internal Cortex-M4 A1 address. EPIOS0 should be connected to A0 of 16-bit memories.

11.4.3.1 Control Pins

The main three strobes are Address Latch Enable (ALE), Write (WRn), and Read (RDn, sometimes called OEn). Note that the timings are designed for older logic and so are hold-time versus setup-time specific. The polarity of the read and write strobes can be active High or active Low by clearing or setting the RDHIGH and WRHIGH bits in the **EPI Host-Bus n Configuration (EPIHBNCFGn)** register.

The ALE can be changed to an active-low chip select signal, CSn, through the **EPIHBNCFGn** register. The ALE is best used for Host-Bus muxed mode in which EPI address and data pins are shared. All Host-Bus accesses have an address phase followed by a data phase. The ALE indicates to an external latch to capture the address then hold it until the data phase. The polarity of the ALE

can be active High or Low by clearing or setting the **ALEHIGH** bit in the **EPI Host-Bus n Configuration (EPIHBnCFGn)** register. CSn is best used for Host-Bus unmuxed mode in which EPI address and data pins are separate. The CSn indicates when the address and data phases of a read or write access are occurring. Both the ALE and the CSn modes can be enhanced to access four external devices using settings in the **EPIHBnCFGn** register. PSRAM accesses must use both ALE and CSn . Wait states can be added to the data phase of the access using the WRWS and RDWS bits in the **EPIHBnCFGn** register. Additionally, within these wait state options, the WRWSM and RDWSM bit of the **EPIHBnTIMEn** register can be set to reduce the given wait states by 1 EPI clock cycle for finer granularity.

For FIFO mode, the ALE is not used, and two input holds are optionally supported to gate input and output to what the XFIFO can handle. FIFO mode is only applicable in EPI asynchronous mode.

Host-Bus 8 and Host-Bus 16 modes are very configurable. The user has the ability to connect 1,2, or 4 external devices to the EPI signals, as well as control whether byte select signals are provided in HB16 mode. These capabilities depend on the configuration of the MODE field in the **EPIHBnCFG** register, the CSCFG field and the CSCFGEEXT bit in the **EPIHBnCFGn** register, and the BSEL bit in the **EPIHB16CFG** register. The CSCFGEEXT bit extends the chip select configuration possibilities by providing the most significant bit of the CSCFG field. Refer to Table 11-4 on page 856 for the possible ALE and chip select options that can be programmed by the combination of the CSCFGEEXT and CSCFG bits. Note that CSCFGEEXT is the most significant bit.

Table 11-4. CSCFGEEXT + CSCFG Encodings

Value	Description
0x0	ALE Configuration EPI0S30 is used as an address latch (ALE). The ALE signal is generally used when the address and data are muxed (MODE field in the EPIHB8CFG register is 0x0). The ALE signal is used by an external latch to hold the address through the bus cycle.
0x1	CSn Configuration EPI0S30 is used as a Chip Select (CSn). When using this mode, the address and data are generally not muxed (MODE field in the EPIHB8CFG register is 0x1). However, if address and data muxing is needed, the WR signal (EPI0S29) and the RD signal (EPI0S28) can be used to latch the address when CSn is low.
0x2	Dual CSn Configuration EPI0S30 is used as CS0n and EPI0S27 is used as CS1n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map. This configuration can be used for a RAM bank split between 2 devices as well as when using both an external RAM and an external peripheral.
0x3	ALE with Dual CSn Configuration EPI0S30 is used as address latch (ALE), EPI0S27 is used as CS1n, and EPI0S26 is used as CS0n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map.
0x4	ALE with Single CSn Configuration EPI0S30 is used as address latch (ALE) and EPI0S27 is used as CSn.
0x5	Quad CSn Configuration EPI0S30 is used as CS0n and EPI0S27 is used as CS1n. EPI0S34 is used as CS2n and EPI0S33 is used as CS3n.
0x6	ALE with Quad CSn Configuration EPI0S30 is ALE, EPI0S26 is CS0n and EPI0S27 is used as CS1n. EPI0S34 is used as CS2n and EPI0S33 is used as CS3n.
0x7	Reserved

If one of the Dual-Chip-Select modes is selected (CSCFGEXT is 0x0 and CSCFG is 0x2 or 0x3 in the **EPIHBnCFGn** register), both chip selects can share the peripheral, code, or the memory space, or one chip select can use the peripheral space and the other can use the memory or code space. In the **EPIADDRMAP** register, if the EPADR field is not 0x0, the ECADR field is 0x0, and the ERADR field is 0x0, then the address specified by EPADR is used for both chip selects, with CS0n being asserted when the MSB of the address range is 0 and CS1n being asserted when the MSB of the address range is 1. If the ERADR field is not 0x0, the ECADR field is 0x0, and the EPADR field is 0x0, then the address specified by ERADR is used for both chip selects, with the MSB performing the same delineation. If both the EPADR and the ERADR are not 0x0, and the ECADR field is 0x0 and the EPI is configured for dual-chip selects, then CS0n is asserted for either address range defined by EPADR and CS1n is asserted for either address range defined by ERADR. The two chip selects can also be shared between the code space and memory or peripheral space. If the ECADR field is 0x1, ERADR field is 0x0, and the EPADR field is not 0x0, then CS0n is asserted for the address range defined by ECADR and CS1n is asserted for either address range defined by EPADR. If the ECADR field is 0x1, EPADR field is 0x0, and the ERADR field is not 0x0, then CS0n is asserted for the address range defined by ECADR and CS1n is asserted for either address range defined by ERADR.

In quad chip select mode (CSCFGEXT is 0x1 and CSCFG is 0x1 or 0x2 in the **EPIHBnCFG2** register), both the peripheral and the memory space must be enabled. In the **EPIADDRMAP** register, the EPADR field is 0x3, the ERADR field is 0x3, and the ECADR field is 0x0. With this configuration, CS0n asserts for the address range beginning at 0x6000.0000, CS1n asserts for 0x8000.0000, CS2n for 0xA000.0000, and CS3n for 0xC000.0000. Table 11-5 on page 857 gives a detailed explanation of chip select address range mappings based on combinations of enabled peripheral and memory space.

Note: Only one memory area can be mapped to a single chip select. Enabling multiple memory areas for one chip select may produce unexpected results.

Table 11-5. Dual- and Quad- Chip Select Address Mappings

Chip Select Mode	ERADR	EPADR	ECADR	CS0 ^a	CS1	CS2	CS3
Dual-chip select	0x0	0x1 or 0x2	0x0	EPADR defined address range (0xA000.000 or 0xC000.0000)	EPADR defined address range (0xA000.000 or 0xC000.0000)	N/A	N/A
Dual-chip select	0x1 or 0x2	0x0	0x0	ERADR defined address range (0x6000.000 or 0x8000.000)	ERADR defined address range (0x6000.000 or 0x8000.000)	N/A	N/A
Dual-chip select	0x1 or 0x2	0x1 or 0x2	0x0	EPADR defined address range (0xA000.000 or 0xC000.0000)	ERADR defined address range (0x6000.000 or 0x8000.000)	N/A	N/A
Dual-chip select	0x0	0x1 or 0x2	0x1	ECADR defined address range (0x1000.000)	EPADR defined address range (0xA000.0000 or 0xC000.0000)	N/A	N/A
Dual-chip select	0x1 or 0x2	0x0	0x1	ECADR defined address range (0x1000.000)	ERADR defined address range (0x6000.000 or 0x8000.000)	N/A	N/A
Quad-chip select	0x3	0x3	0x0	0x6000.0000	0x8000.0000	0xA000.0000	0xC000.0000

a. When CS0 & CS1 share address space, CS0 asserts when the MSB of the address is 0 and CS1, when the MSB of the address is '1.'

The MODE field of the **EPIHBnCFGn** registers configure the interface for the chip selects, which support ADMUX or ADNOMUX. See Table 11-6 on page 858 for details on which configuration register controls each chip select. If the CSBAUD bit is clear, all chip selects are configured by the MODE bit field of the **EPIHBnCFG** register.

If the CSBAUD bit in the **EPIHBnCFG2** register is set in Dual-chip select mode, the 2 chip selects can use different clock frequencies, wait states and strobe polarity. If the CSBAUD bit is clear, both chip selects use the clock frequency, wait states, and strobe polarity defined for CS0n. Additionally, if the CSBAUD bit is set, the two chip selects can use different interface modes. If any interface modes are programmed to ADMUX, then dual chip select mode must include the ALE capability. In quad chip select mode, if the CSBAUD bit in the **EPIHBnCFG2** register is set, the 4 chip selects can use different clock frequencies, wait states and strobe polarity. If the CSBAUD bit is clear, all chip selects use the clock frequency, wait states, and strobe polarity defined for CS0n. If the CSBAUD bit is set, the four chip selects can use different interface modes.

Table 11-6. Chip Select Configuration Register Assignment

Configuration Register ^a	Corresponding Chip Select
EPIHBnCFG	CS0n
EPIHBnCFG2	CS1n
EPIHBnCFG3	CS2n
EPIHBnCFG4	CS3n

a. If the CSBAUD bit in the **EPIHBnCFG2** register is clear and multiple chip selects are enabled, then all chip selects are configured by the MODE bit field in the **EPIHBnCFG** register.

Note that multiple chip select modes do not allow the intermixing of Host-Bus 8 and Host-Bus16 modes.

When BSEL=1 in the **EPIHB16CFG** register, byte select signals are provided, so byte-sized data can be read and written at any address, however these signals reduce the available address width by 2 pins. The byte select signals are active Low. BSEL0n corresponds to the LSB of the halfword, and BSEL1n corresponds to the MSB of the halfword.

When BSEL=0, byte reads and writes at odd addresses only act on the even byte, and byte writes at even addresses write invalid values into the odd byte. As a result, accesses should be made as half-words (16-bits) or words (32-bits). In C/C++, programmers should use only short int and long int for accesses. Also, because data accesses in HB16 mode with no byte selects are on 2-byte boundaries, the available address space is doubled. For example, 28 bits of address accesses 512 MB in this mode. Table 11-7 on page 858 shows the capabilities of the HB8 and HB16 modes as well as the available address bits with the possible combinations of these bits.

Although the EPIOS31 signal can be configured for the EPI clock signal in Host-Bus mode, it is not required and should be configured as a GPIO to reduce EMI in the system.

Table 11-7. Capabilities of Host Bus 8 and Host Bus 16 Modes

Host Bus Type	MODE	CSCFGEXT	CSCFG	Max # of External Devices	BSEL	Byte Access	Available Address	Addressable Memory

a. If byte selects are not used, data accesses are on 2-byte boundaries. As a result, the available address space is doubled.

b. Two EPI signals are used for byte selects, reducing the available address space by two bits.

Table 11-8 on page 860 shows how the `EPI[31:0]` signals function while in Host-Bus 8 mode. Notice that the signal configuration changes based on the address/data mode selected by the `MODE` field in the `EPIHB8CFGn` register and on the chip select configuration selected by the `CSCFG` and `CSCFGEXT` field in the `EPIHB8CFG2` register.

Although the `EPIO8S31` signal can be configured for the EPI clock signal in Host-Bus mode, it is not required and should be configured as a GPIO to reduce EMI in the system. Any unused EPI controller signals can be used as GPIOs or another alternate function.

a. "X" indicates the state of this field is a don't care.

b. When an entry straddles several row, the signal configuration is the same for all rows.

c. The clock signal is not required for this mode.

Table 11-9 on page 862 shows how the EPI[31:0] signals function while in Host-Bus 16 mode. Notice that the signal configuration changes based on the address/data mode selected by the MODE field in the **EPIHB16CFGn** register, on the chip select configuration selected by the CSCFG and CSCFGEEXT field in the same register, and on whether byte selects are used as configured by the BSEL bit in the **EPIHB16CFG** register.

Although the EPI0S31 signal can be configured for the EPI clock signal in Host-Bus mode, it is not required and should be configured as a GPIO to reduce EMI in the system. Any unused EPI controller signals can be used as GPIOs or another alternate function.

a. "X" indicates the state of this field is a don't care.

b. In this mode, half-word accesses are used. A0 is the LSB of the address and is equivalent to the internal Cortex-M3 A1 address. This pin should be connected to A0 of 16-bit memories.

c. When an entry straddles several row, the signal configuration is the same for all rows.

d. The clock signal is not required for this mode.

The RDYEN in the **EPIHBnCFG** enables the monitoring of the external iRDY pin to stall accesses. On the rising edge of EPI clock, if iRDY is low, access is stalled. The **IRDYDLY** can program the number of EPI clock cycles in advance to the stall (1,2 or 3) as shown in Figure 11-5 on page 866. This is a conceptual timing diagram of how the iRDY signal works with different **IRDYDLY** configurations. When enabled, the iRDY stalls the EPI's internal states, while **IRDYDLY** controls the delay pipeline when this stall takes affect. The iRDY signal can be connected to multiple devices with a pull up resistor as shown in Figure 11-6 on page 866. Note that when multiple PSRAMs are connected to iRDY, the **EPIHPnCFG** registers must be programmed to the same iRDY signal polarity through the **IRDYINV** bit. When connected to a PSRAM, iRDY is used to control the address to data latency.

Figure 11-5. iRDY Access Stalls, IRDYDLY==01, 10, 11**Figure 11-6. iRDY Signal Connection**

11.4.3.2 PSRAM Support

The EPI Host Bus supports both a synchronous and asynchronous interface to PSRAM memory when configured in 16-bit bus multiplexed mode. The **EPIHPSRAM** register holds the values for the PSRAM's bus configuration registers (CR). The contents of the **EPIHPSRAM** register can be sent to different memories depending on which WRCRE or RDCRE bit is set in the various **EPIHB16CFGn** registers. For example, if the WRCRE bit is enabled in **EPIHB16CFG**, then the CRE signal asserts and the contents are sent to the memory enabled by CS0. Enabling the WRCRE or RDCRE bit in **EPIHB16CFG2** register activates CS1n during a PSRAM configuration register write or read. The WRCRE and RDCRE bit in **EPIHB16CFG3** corresponds to CS2n and **EPIHB16CFG4**, to CS3n. The WRCRE bit clears when the transfer is done. There must not be any system access or non-blocking read activity during the CRE read or write-enable transfer. During a write to the PSRAM's CR, the configuration data is written out on data pins [20:0] of the EPI bus. For a PSRAM configuration read access, the RDCRE bit in the **EPIHB16CFG** register is set to signal that the next access is a read of the PSRAM configuration register (CR). The address for the CR is written to bits CR[19:18] of the **EPIHPSRAM** register. The read data is returned at CR bits [15:0] of the **EPIHPSRAM** register.

Note: ■ CRE read and write operations may only occur in asynchronous mode. During synchronous mode the CRE bit should be disabled. Setting the CRE bit during synchronous PSRAM accesses can lead to unpredictable behavior.

- When the chip select is programmed to access the PSRAM, the MODE bit of the **EPIHBnCFGn** register must be programmed to enable address and data muxed (ADMUX). Page mode accesses are not supported by the EPI.
- BURST is optimized for word-length bursting for SDRAM and PSRAM accesses.

The subsequent list identifies the steps for initializing the PSRAM interface:

1. Follow the EPI initialization steps in “Initialization and Configuration” on page 850.
2. Enable Host Bus 16 Mode by setting the MODE bits in the **EPICFG** register to 0x13. Choose between an integer or formula clock divide for the baud rate by configuring the INTDIV bit in the **EPICFG** register.
3. Configure the **EPIBAUD** register to the desired baud rate.
4. Since the EPI module only supports asynchronous programming of the configuration registers, clock gate the EPI clock by programming both the CLKGATE and CLKGATEI bits in the **EPIHB16CFG** register to 0.
5. Prepare for writing the PSRAM's Bus Configuration Register by setting the ALEHIGH = 1 and MODE=0x0 in the **EPIHB16CFG** register.
6. Program the **EPIHBPSRAM** register to be loaded into the CR register of the PSRAM by configuring bits [21:0].
 - CR[20:19] =0x0, reserved
 - CR[19:18] = 0x2 to enable configuring of the CR register
 - CR[15]= 0x1 to enable asynchronous access
 - CR [14] = 0 if the iRDY signal is used for memory transfers; if the design will not use the iRDY signal CR[14] should be cleared.
 - CR[13:11] must be programmed to have a matching read and write wait state configuration as is programmed in the **EPIHB16CFG** and **EPIHB16TIME** register.
 - CR[10] configures the polarity of the WAIT signal and should match the configuration of the IRDYINV bit in the **EPIHB16CFG** register.
 - CR[8]=0x1 to configure the appropriate wait configuration of the data
 - CR[2:0]=0x7 since the EPI interface in PSRAM mode is a continuous burst access.
7. Set the WRCRE bit in the **EPIHB16CFGn** register to initiate a write from the **EPIHBPSRAM** register to PSRAM's CR register.

Note: If the PSRAM's CR register must be reprogrammed after initialization, the application should allow the previous transfer to complete before beginning configuration to ensure proper PSRAM functionality.

Table 11-10. PSRAM Fixed Latency Wait State Configuration

Latency Counter	Latency in Clocks	RDWS[1:0]/WRWS[1:0]	RWSM/WRWSM
BCR Code 2	3	0x0	0
BCR Code 3	4	0x1	1
BCR Code 4	5	0x1	0
BCR Code 5	6	0x2	1
BCR Code 6	7	0x2	0
BCR Code 8	9	0x3	0

In variable initial latency mode, the memory's WAIT (iRDY) pin guides the EPI module when to read and write. The WAIT (iRDY) pin stalls the access for the duration of the latency and adds cycles if there is a refresh collision. To get the best performance, set CR[13:11] = 0x2, the WRWS field of the **EPIHB16CFG** register to 0x0, and the RWSM and RDWSM bit of the **EPI16TIMEEn** register to 0. For the WAIT pin to be recognized correctly set the IRDYDLY bit in the **EPI16TIMEEn** register to 1 and the CR[8] = 1 in the **EPIHBPSRAM** register.

Note: Wait state latency works differently in PSRAM Burst mode than in other modes. In PSRAM Burst mode the RDWS and WRWS bit fields define the latency for only the first access of the write or read cycle. Every access after that is a single access.

Figure 11-7 on page 868 and Figure 11-8 on page 869 depict a PSRAM burst read and write.

Figure 11-7. PSRAM Burst Read

Figure 11-8. PSRAM Burst Write

Note that if a read or write transfer attempts to begin during a refresh event, the transfer is held off by the assertion of the iRDY pin by the memory to the EPI module. Figure 11-9 on page 870 and Figure 11-10 on page 870 depict the delay in data transfer during a refresh collision.

Figure 11-9. Read Delay During Refresh Event**Figure 11-10. Write Delay During Refresh Event**

11.4.3.3 Host Bus 16-bit Muxed Interface

Figure 11-11 on page 871 shows how to connect the EPI signals to a 16-bit SRAM and a 16-bit Flash memory with muxed address and memory using byte selects and dual chip selects with ALE. This schematic is just an example of how to connect the signals; timing and loading have not been analyzed. In addition, not all bypass capacitors are shown.

Figure 11-11. Example Schematic for Muxed Host-Bus 16 Mode

11.4.3.4 Speed of Transactions

The COUNT0 field in the **EPIBAUD** register must be configured to set the main transaction rate based on what the slave device can support (including wiring considerations). The main control transitions are normally $\frac{1}{2}$ the baud rate (COUNT0 = 1) because the EPI block forces data versus control to change on alternating clocks. When using dual chip selects, each chip select can access the bus using differing baud rates by setting the CSBAUD bit in the **EPIHBnCFG2** register. In this case, the COUNT0 field controls the CS0n transactions, and the COUNT1 field controls the CS1n transactions. When using quad chip select mode, the COUNT0 bit field of the **EPIBAUD2** register controls the baud rate of CS2n and the COUNT1 bit field is programmed to control the baud rate of CS3n.

Additionally, the Host-Bus mode provides read and write wait states for the data portion to support different classes of device. These wait states stretch the data period (hold the rising edge of data strobe) and may be used in all four sub-modes. The wait states are set using the WRWS and RDWS bits in the **EPI Host-Bus n Configuration (EPIHBnCFGn)** register. The WRWS and RDWS bits are enhanced with more precision by WRWSM and RDWSM bits in the **EPIHBnTIMEn** registers. Note none of the wait state configuration bits can be set concurrently with the BURST bit in the same **EPIHBnCFGn** register. See Table 11-11 on page 872 for programming information.

Table 11-11. Data Phase Wait State Programming

RDWS or WRWS Encoding in EPIHBnCFGn Register	RDWSM or WRWSM Encoding in EPIHBnTIMEn Registers	Data Phase Wait States
0x0	1	1 EPI clocks
0x0	0	2 EPI clocks
0x1	1	3 EPI clocks
0x1	0	4 EPI clocks
0x2	1	5 EPI clocks
0x2	0	6 EPI clocks
0x3	1	7 EPI clocks
0x3	0	8 EPI clocks

The CAPWIDTH bit in **EPIHBnTIMEn** registers controls the delay between Host-Bus transfers. When the CSBAUD bit is set and multi-chip selects have been configured in the **EPIHBnCFG2** registers, delay takes an additional clock cycle to adjust the clock rate of different chip selects.

Word read and write transactions can be enhanced through the enabling of the BURST bit in the **EPIHB16CFGn** registers.

11.4.3.5 Sub-Modes of Host Bus 8/16

The EPI controller supports four variants of the Host-Bus model using 8 or 16 bits of data in all four cases. The four sub-modes are selected using the MODE bits in the **EPIHBnCFG** register, and are:

1. Address and data are muxed. This scheme is used by many 8051 devices, some Microchip PIC parts, and some ATmega parts. When used for standard SRAMs, a latch must be used between the microcontroller and the SRAM. This sub-mode is provided for compatibility with existing devices that support data transfers without a latch (that is, CPLDs). In general, the de-muxed sub-mode should normally be used. The ALE configuration should be used in this mode, as all Host-Bus accesses have an address phase followed by a data phase. The ALE indicates to an external latch to capture the address then hold until the data phase. The ALE configuration is controlled by configuring the CSCFG and CSCFGEXT field to be 0x0 in the **EPIHBnCFG2** register.

The ALE can be enhanced to access two or four external devices with four separate CSn signals. By configuring the CSCFG field to be 0x3 and the CSCFGEEXT bit to be 0 in the **EPIHBnCFG2** register, EPIOS30 functions as ALE, EPIOS27 functions as CS1n, and EPIOS26 functions as CS0n. When the CSCFG field is set to 0x0 and the CSCFGEEXT bit is set to 1 in the **EPIHBnCFG2** register, EPIOS30 functions as ALE, EPIOS33 functions as CS3n, EPIOS34 functions as CS2n, EPIOS27 functions as CS1n, and EPIOS26 functions as CS0n. The CSn is best used for Host-Bus unmuxed mode, in which EPI address and data pins are separate. The CSn indicates when the address and data phases of a read or write access are occurring.

2. Address and data are separate with 8 or 16 bits of data and up to 20 bits of address (1 MB). This scheme is used by more modern 8051 devices, as well as some PIC and ATmega parts. This mode is generally used with SRAMs in continuous read modes, many EEPROMs, and many NOR Flash memory devices. Note that there is no hardware command write support for Flash memory devices; this mode should only be used for Flash memory devices programmed at manufacturing time. If a Flash memory device must be written and does not support a direct programming model, the command mechanism must be performed in software. The CSn configuration should be used in this mode. The CSn signal indicates when the address and data phases of a read or write access is occurring. The CSn configuration is controlled by configuring the CSCFG field to be 0x1 and the CSCFGEEXT bit to be 0 in the **EPIHBnCFG2** register.
3. Continuous read mode where address and data are separate. This read sub-mode is used by some SRAMs and can read more quickly by only changing the address (and not using RDn/OEn strobing). In this sub-mode, reads are performed by keeping the read mode selected (output enable is asserted) and then changing the address pins. The data pins are changed by the SRAM after the address pins change. For example, to read data from address 0x100 and then 0x101, the EPI controller asserts the output-enable signal and then configures the address pins to 0x100; the EPI controller then captures what is on the data pins and increments A0 to 1 (so the address is now 0x101); the EPI controller then captures what is on the data pins. Note that this mode consumes higher power because the SRAM must continuously drive the data pins. This mode is not practical in HB16 mode for normal SRAMs because there are generally not enough address bits available. Writes are not permitted in this mode.
4. FIFO mode uses 8 or 16 bits of data, removes ALE and address pins and optionally adds external XFIFO FULL/EMPTY flag inputs. This scheme is used by many devices, such as radios, communication devices (including USB2 devices), and some FPGA configurations (FIFO through block RAM). This sub-mode provides the data side of the normal Host-Bus interface, but is paced by the FIFO control signals. It is important to consider that the XFIFO FULL/EMPTY control signals may stall the interface and could have an impact on blocking read latency from the processor or μDMA. Note that the EPI FIFO can only be used in asynchronous mode.

For the three modes above (1, 2, 4) that the Host-Bus 16 mode supports, byte select signals can be optionally implemented by setting the BSEL bit in the **EPIHB16CFG** register.

Note: Byte accesses should not be attempted if the BSEL bit has not been enabled in Host-Bus 16 Mode.

See Electrical Characteristics (Pending) for timing details for the Host-Bus mode.

11.4.3.6 Bus Operation

Bus operation is the same in Host-Bus 8 and Host-Bus 16 modes and is asynchronous. Timing diagrams show both ALE and CSn operation. The optional HB16 byte select signals have the same timing as the address signals. If wait states are required in the bus access, they can be inserted during the data phase of the access using the WRWS and RDWS bits in the **EPIHBnCFG2** register.

Each wait state adds 2 EPI clock cycles to the duration of the WRn or RDn strobe. During idle cycles, the address and muxed address data signals maintain the state of the last cycle.

Figure 11-12 on page 874 shows a basic Host-Bus read cycle. Figure 11-13 on page 874 shows a basic Host-Bus write cycle. Both of these figures show address and data signals in the non-multiplexed mode (MODE field is 0x1 in the **EPIHBNCFG** register).

Figure 11-12. Host-Bus Read Cycle, MODE = 0x1, WRHIGH = 0, RDHIGH = 0

^a BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

Figure 11-13. Host-Bus Write Cycle, MODE = 0x1, WRHIGH = 0, RDHIGH = 0

^a BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

Figure 11-14 on page 875 shows a write cycle with the address and data signals multiplexed (MODE field is 0x0 in the **EPIHBNCFG** register). A read cycle would look similar, with the RDn strobe being asserted along with CSn and data being latched on the rising edge of RDn.

Figure 11-14. Host-Bus Write Cycle with Multiplexed Address and Data, MODE = 0x0, WRHIGH = 0, RDHIGH = 0

^a BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

When using ALE with dual CSn configuration (CSCFGEXT bit is 0 and the CSCFG field is 0x3 in the **EPIHBnCFG2** register) or quad chip select (CSCFGEXT bit is 1 and CSCSFG is 0x2), the appropriate CSn signal is asserted at the same time as ALE, as shown in Figure 11-15 on page 875.

Figure 11-15. Host-Bus Write Cycle with Multiplexed Address and Data and ALE with Dual or Quad CSn

^a BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

Figure 11-16 on page 875 shows continuous read mode accesses. In this mode, reads are performed by keeping the read mode selected (output enable is asserted) and then changing the address pins. The data pins are changed by the SRAM after the address pins change.

Figure 11-16. Continuous Read Mode Accesses

FIFO mode accesses are the same as normal read and write accesses, except that the ALE signal and address pins are not present. Two input signals can be used to indicate when the XFIFO is full or empty to gate transactions and avoid overruns and underruns. The FFULL and FEMPTY signals are synchronized and must be recognized as asserted by the microcontroller for 2 system clocks before they affect transaction status. The MAXWAIT field in the **EPIHBNCFG** register defines the maximum number of EPI clocks to wait while the FEMPTY or FFULL signal is holding off a transaction. Figure 11-17 on page 876 shows how the FEMPTY signal should respond to a write and read from the XFIFO. Figure 11-18 on page 876 shows how the FEMPTY and FFULL signals should respond to 2 writes and 1 read from an external FIFO that contains two entries.

Figure 11-17. Write Followed by Read to External FIFO

Figure 11-18. Two-Entry FIFO

11.4.4 General-Purpose Mode

The **General-Purpose Mode Configuration (EPIGPCFG)** register is used to configure the control, data, and address pins, if used. Any unused EPI controller signals can be used as GPIOs or another alternate function. The general-purpose configuration can be used for custom interfaces with FPGAs, CPLDs, and digital data acquisition and actuator control.

General-Purpose mode is designed for three general types of use:

- Extremely high-speed clocked interfaces to FPGAs and CPLDs. Three sizes of data and optional address are supported. Framing and clock-enable functions permit more optimized interfaces.
- General parallel GPIO. From 1 to 32 pins may be written or read, with the speed precisely controlled by the **EPIBAUD** register baud rate (when used with the WFIFO and/or the NBRFIFO) or by the rate of accesses from software or µDMA. Examples of this type of use include:

- Reading 20 sensors at fixed time periods by configuring 20 pins to be inputs, configuring the COUNT0 field in the **EPIBAUD** register to some divider, and then using non-blocking reads.
- Implementing a very wide ganged PWM/PCM with fixed frequency for driving actuators, LEDs, etc.
- General custom interfaces of any speed.

The configuration allows for choice of an output clock (free-running or gated), a framing signal (with frame size), a ready input (to stretch transactions), an address (of varying sizes), and data (of varying sizes). Additionally, provisions are made for separating data and address phases.

The interface has the following optional features:

- Use of the EPI clock output is controlled by the CLKPIN bit in the **EPIGPCFG** register. Unclocked uses include general-purpose I/O and asynchronous interfaces (optionally using RD and WR strobes). Clocked interfaces allow for higher speeds and are much easier to connect to FPGAs and CPLDs (which usually include input clocks).
- EPI clock, if used, may be free running or gated depending on the CLKGATE bit in the **EPIGPCFG** register. A free-running EPI clock requires another method for determining when data is live, such as the frame pin or RD/WR strobes. A gated clock approach uses a setup-time model in which the EPI clock controls when transactions are starting and stopping. The gated clock is held high until a new transaction is started and goes high at the end of the cycle where RD/WR/FRAME and address (and data if write) are emitted.
- Use of the RD and WR outputs is controlled by the RW bit in the **EPIGPCFG** register. For interfaces where the direction is known (in advance, related to frame size, or other means), these strobes are not needed. For most other interfaces, RD and WR are used so the external peripheral knows what transaction is taking place, and if any transaction is taking place.
- Separation of address/request and data phases may be used on writes using the WR2CYC bit in the **EPIGPCFG** register. This configuration allows the external peripheral extra time to act. Address and data phases must be separated on reads. When configured to use an address as specified by the ASIZE field in the **EPIGPCFG** register, the address is emitted on the first cycle with the RD strobe (first cycle) and data is expected to be returned on the next cycle (when RD is not asserted). If no address is used, then RD is asserted on the first cycle and data is captured on the second cycle (when RD is not asserted), allowing more setup time for data.

Note: When WR2CYC = 0, write data is valid when the WR strobe is asserted (High). When WR2CYC = 1, write data is valid when the WR strobe is Low after being asserted (High).

For writes, the output may be in one or two cycles. In the two-cycle case, the address (if any) is emitted on the first cycle with the WR strobe and the data is emitted on the second cycle (with WR not asserted). Although split address and write data phases are not normally needed for logic reasons, it may be useful to make read and write timings match. If 2-cycle reads or writes are used, the RW bit is automatically set.

- Address may be emitted (controlled by the ASIZE field in the **EPIGPCFG** register). The address may be up to 4 bits (16 possible values), up to 12 bits (4096 possible values), or up to 20 bits (1 M possible values). Size of address limits size of data, for example, 4 bits of address support up to 24 bits data. 4-bit address uses EPIO[27:24]; 12-bit address uses EPIO[27:16]; 20-bit address uses EPIO[27:8]. The address signals may be used by the external peripheral as an address, code (command), or for other unrelated uses (such as a chip enable). If the chosen address/data combination does not use all of the EPI signals, the unused pins can be

used as GPIOs or for other functions. For example, when using a 4-bit address with an 8-bit data, the pins assigned to `EPIOS0[23:8]` can be assigned to other functions.

- Data may be 8 bits, 16 bits, 24 bits, or 32 bits (controlled by the `DSIZE` field in the **EPIGPCFG** register). By default, the EPI controller uses data bits [7:0] when the `DSIZE` field in the **EPIGPCFG** register is 0x0; data bits [15:0] when the `DSIZE` field is 0x1; data bits [23:0] when the `DSIZE` field is 0x2; and data bits [31:0] when the `DSIZE` field is 0x3. 32-bit data cannot be used with address or EPI clock or any other signal. 24-bit data can only be used with 4-bit address or no address.
- When using the EPI controller as a GPIO interface, writes are FIFOed (up to 4 can be held at any time), and up to 32 pins are changed using the **EPIBAUD** clock rate specified by `COUNT0`. As a result, output pin control can be very precisely controlled as a function of time. By contrast, when writing to normal GPIOs, writes can only occur 8-bits at a time and take up to two clock cycles to complete. In addition, the write itself may be further delayed by the bus due to μ DMA or draining of a previous write. With both GPIO and the EPI controller, reads may be performed directly, in which case the current pin states are read back. With the EPI controller, the non-blocking interface may also be used to perform reads based on a fixed time rule via the **EPIBAUD** clock rate.

Table 11-12 on page 878 shows how the `EPIOS[31:0]` signals function while in General-Purpose mode. Notice that the address connections vary depending on the data-width restrictions of the external peripheral.

Table 11-12. EPI General-Purpose Signal Connections

a. In this mode, half-word accesses are used. AO is the LSB of the address and is equivalent to the system A1 address.

b. In this mode, word accesses are used. AO is the LSB of the address and is equivalent to the system A2 address.

11.4.4.1 Bus Operation

A basic access is 1 EPI clock for write cycles and 2 EPI clocks for read cycles. An additional EPI clock can be inserted into a write cycle by setting the WR2CYC bit in the **EPIGPCFG** register.

Figure 11-19. Single-Cycle Single Write Access, FRM50=0, FRMCNT=0, WR2CYC=0

Figure 11-20. Two-Cycle Read, Write Accesses, FRM50=0, FRMCNT=0, WR2CYC=1**Figure 11-21. Read Accesses, FRM50=0, FRMCNT=0**

FRAME Signal Operation

The operation of the **FRAME** signal is controlled by the **FRMCNT** and **FRM50** bits. When **FRM50** is clear, the **FRAME** signal is high whenever the **WR** or **RD** strobe is high. When **FRMCNT** is clear, the **FRAME** signal is simply the logical OR of the **WR** and **RD** strobes so the **FRAME** signal is high during every read or write access, see Figure 11-22 on page 881.

Figure 11-22. FRAME Signal Operation, FRM50=0 and FRMCNT=0

If the FRMCNT field is 0x1, then the FRAME signal pulses high during every other read or write access, see Figure 11-23 on page 881.

Figure 11-23. FRAME Signal Operation, FRM50=0 and FRMCNT=1

If the FRMCNT field is 0x2 and FRM50 is clear, then the FRAME signal pulses high during every third access, and so on for every value of FRMCNT, see Figure 11-24 on page 881.

Figure 11-24. FRAME Signal Operation, FRM50=0 and FRMCNT=2

When FRM50 is set, the FRAME signal transitions on the rising edge of either the WR or RD strobes. When FRMCNT=0, the FRAME signal transitions on the rising edge of WR or RD for every access, see Figure 11-25 on page 881.

Figure 11-25. FRAME Signal Operation, FRM50=1 and FRMCNT=0

When FRMCNT=1, the FRAME signal transitions on the rising edge of the WR or RD strobes for every other access, see Figure 11-26 on page 882.

Figure 11-26. FRAME Signal Operation, FRM50=1 and FRMCNT=1

When **FRMCNT=2**, the FRAME signal transitions the rising edge of the WR or RD strobes for every third access, and so on for every value of **FRMCNT**, see Figure 11-27 on page 882.

Figure 11-27. FRAME Signal Operation, FRM50=1 and FRMCNT=2

EPI Clock Operation

If the **CLKGATE** bit in the **EPIGPCFG** register is clear, the EPI clock always toggles when General-purpose mode is enabled. If **CLKGATE** is set, the clock is output only when a transaction is occurring, otherwise the clock is held high. If the **WR2CYC** bit is clear, the EPI clock begins toggling 1 cycle before the WR strobe goes High. If the **WR2CYC** bit is set, the EPI clock begins toggling when the WR strobe goes High. The clock stops toggling after the first rising edge after the WR strobe is deasserted. The RD strobe operates in the same manner as the WR strobe when the **WR2CYC** bit is set. See Figure 11-28 on page 882 and Figure 11-29 on page 883.

Figure 11-28. EPI Clock Operation, CLKGATE=1, WR2CYC=0

Figure 11-29. EPI Clock Operation, CLKGATE=1, WR2CYC=1

11.5 Register Map

Table 11-13 on page 883 lists the EPI registers. The offset listed is a hexadecimal increment to the register's address, relative to the base address of 0x400D.0000. Note that the EPI controller clock must be enabled before the registers can be programmed (see page 402). There must be a delay of 3 system clocks after the EPI module clock is enabled before any EPI module registers are accessed.

Note: A write immediately followed by a read of the same register, may not return correct data. A delay (instruction or NOP) must be inserted between the write and the read for correct operation. Read-write does not have this issue, so use of read-write for clear of error interrupt cause is not affected.

Note: For all versions of EPI, only WORD read and write accesses to registers are supported.

11.6 Register Descriptions

This section lists and describes the EPI registers, in numerical order by address offset.

Register 1: EPI Configuration (EPICFG), offset 0x000

Important: The MODE field determines which configuration register is accessed for offsets 0x010 and 0x014. Any write to the EPICFG register resets the register contents at offsets 0x010 and 0x014.

The configuration register is used to enable the block, select a mode, and select the basic pin use (based on the mode). Note that attempting to program an undefined MODE field clears the BLKEN bit and disables the EPI controller.

EPI Configuration (EPICFG)

Base 0x400D.0000

Offset 0x000

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	INTDIV	RW	0	Integer Clock Divider Enable Value Description 0 EPIBAUD register values create formula clock divide. 1 EPIBAUD register values create integer clock divide.
7:5	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	BLKEN	RW	0	Block Enable Value Description 0 The EPI controller is disabled. 1 The EPI controller is enabled.

Register 2: EPI Main Baud Rate (EPIBAUD), offset 0x004

The system clock is used internally to the EPI Controller. The baud rate counter can be used to divide the system clock down to control the speed on the external interface. If the mode selected emits an external EPI clock, this register defines the EPI clock emitted. If the mode selected does not use an EPI clock, this register controls the speed of changes on the external interface. Care must be taken to program this register properly so that the speed of the external bus corresponds to the speed of the external peripheral and puts acceptable current load on the pins. COUNT0 is the bit field used in all modes except in HB8 and HB16 modes with dual chip selects and quad chip selects when different baud rates are selected, see page 908 and page 914. If different baud rates are used, COUNT0 is associated with the address range specified by CS0n and COUNT1 is associated with the address range specified by CS1. The **EPIBAUD2** register configures the baud rates for CS2n and CS3n.

The COUNTn field is not a straight divider or count. The EPI Clock on EPI0S31 is related to the COUNTn field and the system clock as follows:

If COUNTn = 0,

$$\text{EPIClockFreq} = \text{SystemClockFreq}$$

otherwise:

$$\text{EPIClockFreq} = \frac{\text{SystemClockFreq}}{\left(\left\lfloor \frac{\text{COUNTn}}{2} \right\rfloor + 1\right) \times 2}$$

where the symbol around COUNTn/2 is the floor operator, meaning the largest integer less than or equal to COUNTn/2.

So, for example, a COUNTn of 0x0001 results in a clock rate of $\frac{1}{2}$ (system clock); a COUNTn of 0x0002 or 0x0003 results in a clock rate of $\frac{1}{4}$ (system clock).

The baud rate counter can also be configured as an integer divide by enabling INTDIV in the **EPICFG** register. When enabled, COUNTn of 0x0000 or 0x0001 results in a clock rate equal to system clock. COUNTn of 0x0002 results in a clock rate of 1/2 (system clock). COUNTn of 0x0003 results in a clock rate of 1/3 (system clock).

Register 3: EPI Main Baud Rate (EPIBAUD2), offset 0x008

The system clock is used internally to the EPI Controller. The baud rate counter can be used to divide the system clock down to control the speed on the external interface. If the mode selected emits an external EPI clock, this register defines the EPI clock emitted. If the mode selected does not use an EPI clock, this register controls the speed of changes on the external interface. Care must be taken to program this register properly so that the speed of the external bus corresponds to the speed of the external peripheral and puts acceptable current load on the pins. COUNT0 and COUNT1 are used in quad chip select mode when different baud rates are selected, page 908 or page 914. If different baud rates are used, COUNT0 is associated with the address range specified by CS2n and COUNT1 is associated with the address range specified by CS3n.

The COUNTn field is not a straight divider or count. The EPI Clock on EPIO0S31 is related to the COUNTn field and the system clock as follows:

If COUNTn = 0,

$$\text{EPIClockFreq} = \text{SystemClockFreq}$$

otherwise:

$$\text{EPIClockFreq} = \frac{\text{SystemClockFreq}}{\left(\left\lfloor \frac{\text{COUNTn}}{2} \right\rfloor + 1\right) \times 2}$$

where the symbol around COUNTn/2 is the floor operator, meaning the largest integer less than or equal to COUNTn/2.

So, for example, a COUNTn of 0x0001 results in a clock rate of $\frac{1}{2}$ (system clock); a COUNTn of 0x0002 or 0x0003 results in a clock rate of $\frac{1}{4}$ (system clock).

EPI Main Baud Rate (EPIBAUD2)

Base 0x400D.0000
Offset 0x008
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	COUNT1	RW	0x0000	CS3n Baud Rate Counter 1 This bit field contains a counter used to divide the system clock by the count. A count of 0 means the system clock is unchanged.
				This bit field is only valid when quad chip selects are enabled by setting the CSCFGEXT bit to 1 and the CSCFG field to 0x1 or 0x2. In addition, the CSBAUD bit must be set in the EPIHBNCFG2 register.

Bit/Field	Name	Type	Reset	Description
15:0	COUNT0	RW	0x0000	<p>CS2n Baud Rate Counter 0</p> <p>This bit field contains a counter used to divide the system clock by the count.</p> <p>A count of 0 means the system clock is unchanged.</p> <p>This bit field is only valid when quad chip selects are enabled by setting the CSCFGEXT to 1 and the CSCFG field to 0x1 or 0x2. In addition, the CSBAUD bit must be set in the EPIHBnCFG2 register.</p>

Register 4: EPI SDRAM Configuration (EPISDRAMCFG), offset 0x010

Important: The MODE field in the EPICFG register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPISDRAMCFG**, the MODE field must be 0x1.

The SDRAM Configuration register is used to specify several parameters for the SDRAM controller. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the SDRAM mode is selected again, the values must be reinitialized.

The SDRAM interface is designed to interface to x16 SDR SDRAMs of 64 MHz or higher, with the address and data pins overlapped (wire ORed on the board). See Table 11-3 on page 852 for pin assignments.

Register 5: EPI Host-Bus 8 Configuration (EPIHB8CFG), offset 0x010

Important: The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIHB8CFG**, the MODE field must be 0x2.

The Host Bus 8 Configuration register is activated when the HB8 mode is selected. The HB8 mode supports muxed address/data (overlay of lower 8 address and all 8 data pins), separate address/data, and address-less FIFO mode. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the HB8 mode is selected again, the values must be reinitialized.

This mode is intended to support SRAMs, Flash memory (read), FIFOs, CPLDs/FPGAs, and devices with an MCU/HostBus slave or 8-bit FIFO interface support.

Refer to Table 11-8 on page 860 for information on signal configuration controlled by this register and the **EPIHB8CFG2** register.

If less address pins are required, the corresponding AFSEL bit (page 799) should not be enabled so the EPI controller does not drive those pins, and they are available as standard GPIOs.

EPI Host-Bus 8 Mode can be configured to use one to four chip selects with and without the use of ALE. If an alternative to chip selects are required, a chip enable can be handled in one of three ways:

1. Manually control via GPIOs.
2. Associate one or more upper address pins to CE. Because CE is normally CEn, lower addresses are not used. For example, if pins EPIOS27 and EPIOS26 are used for Device 1 and 0 respectively, then address 0x6800.0000 accesses Device 0 (Device 1 has its CEn high), and 0x6400.0000 accesses Device 1 (Device 0 has its CEn high). The pull-up behavior on the corresponding GPIOs must be properly configured to ensure that the pins are disabled when the interface is not in use.
3. With certain SRAMs, the ALE can be used as CEn because the address remains stable after the ALE strobe. The subsequent WRn or RDn signals write or read when ALE is low thus providing CEn functionality.

This mode uses no address or ALE. Note that the XFIFO can only be used in asynchronous mode.
Value	Description													
0x0	ADMUX – AD[7:0] Data and Address are muxed.													
0x1	ADNONMUX – D[7:0] Data and address are separate.													
0x2	Continuous Read - D[7:0] This mode is the same as ADNONMUX, but uses address switch for multiple reads instead of OEn strobing.													
0x3	XFIFO – D[7:0] This mode adds XFIFO controls with sense of XFIFO full and XFIFO empty. This mode uses no address or ALE. Note that the XFIFO can only be used in asynchronous mode.													

Register 6: EPI Host-Bus 16 Configuration (EPIHB16CFG), offset 0x010

Important: The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIHB16CFG**, the MODE field must be 0x3.

The Host Bus 16 sub-configuration register is activated when the HB16 mode is selected. The HB16 mode supports muxed address/data (overlay of lower 16 address and all 16 data pins), separated address/data, and address-less FIFO mode. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the HB16 mode is selected again, the values must be reinitialized.

This mode is intended to support SRAMs, Flash memory (read), FIFOs, and CPLDs/FPGAs, and devices with an MCU/HostBus slave or 16-bit FIFO interface support.

Refer to Table 11-9 on page 862 for information on signal configuration controlled by this register and the **EPIHB16CFG2** register.

If less address pins are required, the corresponding AFSEL bit (page 799) should not be enabled so the EPI controller does not drive those pins, and they are available as standard GPIOs.

EPI Host-Bus 16 Mode can be configured to use one to four chip selects with and without the use of ALE. If an alternative to chip selects are required, a chip enable can be handled in one of three ways:

1. Manually control via GPIOs.
2. Associate one or more upper address pins to CE. Because CE is normally CEn, lower addresses are not used. For example, if pins EPIOS27 and EPIOS26 are used for Device 1 and 0 respectively, then address 0x6800.0000 accesses Device 0 (Device 1 has its CEn high), and 0x6400.0000 accesses Device 1 (Device 0 has its CEn high). The pull-up behavior on the corresponding GPIOs must be properly configured to ensure that the pins are disabled when the interface is not in use.
3. With certain SRAMs, the ALE can be used as CEn because the address remains stable after the ALE strobe. The subsequent WRn or RDn signals write or read when ALE is low thus providing CEn functionality.

0	No Byte Selects Data is read and written as 16 bits.													
1	Enable Byte Selects Two EPI signals function as byte select signals to allow 8-bit transfers. See Table 11-9 on page 862 for details on which EPI signals are used.													

Bit/Field	Name	Type	Reset	Description
1:0	MODE	RW	0x0	<p>Host Bus Sub-Mode</p> <p>This field determines which of three Host Bus 16 sub-modes to use. Sub-mode use is determined by the connected external peripheral. See Table 11-9 on page 862 for information on how this bit field affects the operation of the EPI signals. When used with multiple chip select option and the CSBAUD bit is set to 1 in the EPIHB16CFG2 register, this configuration is for CSOn. If the multiple chip select option is enabled and CSBAUD is clear, all chip-selects use the MODE encoding programmed in this register.</p>
Value Description				
0x0 ADMUX – AD[15:0] Data and Address are muxed.				
0x1 ADNONMUX – D[15:0] Data and address are separate. This mode is not practical in HB16 mode for normal peripherals because there are generally not enough address bits available.				
0x2 Continuous Read - D[15:0] This mode is the same as ADNONMUX, but uses address switch for multiple reads instead of OEn strobing. This mode is not practical in HB16 mode for normal SRAMs because there are generally not enough address bits available.				
0x3 XFIFO – D[15:0] This mode adds XFIFO controls with sense of XFIFO full and XFIFO empty. This mode uses no address or ALE. Note that the XFIFO can only be used in asynchronous mode.				

Register 7: EPI General-Purpose Configuration (EPIGPCFG), offset 0x010

Important: The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIGPCFG**, the MODE field must be 0x0.

The General-Purpose configuration register is used to configure the control, data, and address pins. This mode can be used for custom interfaces with FPGAs, CPLDs, and for digital data acquisition and actuator control. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the General-purpose mode is selected again, the register values must be reinitialized.

This mode is designed for 3 general types of use:

- Extremely high-speed clocked interfaces to FPGAs and CPLDs, with 3 sizes of data and optional address. Framing and clock-enable permit more optimized interfaces.
- General parallel GPIO. From 1 to 32 pins may be written or read, with the speed precisely controlled by the baud rate in the **EPIBAUD** register (when used with the NBRFIFO and/or the WFIFO) or by rate of accesses from software or µDMA.
- General custom interfaces of any speed.

The configuration allows for choice of an output clock (free running or gated), a framing signal (with frame size), a ready input (to stretch transactions), read and write strobes, address of varying sizes, and data of varying sizes. Additionally, provisions are made for splitting address and data phases on the external interface.

Table 11-14. CSCFGEXT + CSCFG Encodings

Value	Description
0x0	ALE Configuration EPI0S30 is used as an address latch (ALE). The ALE signal is generally used when the address and data are muxed (MODE field in the EPIHB8CFG register is 0x0). The ALE signal is used by an external latch to hold the address through the bus cycle.
0x1	CSn Configuration EPI0S30 is used as a Chip Select (CSn). When using this mode, the address and data are generally not muxed (MODE field in the EPIHB8CFG register is 0x1). However, if address and data muxing is needed, the WR signal (EPI0S29) and the RD signal (EPI0S28) can be used to latch the address when CSn is low.
0x2	Dual CSn Configuration EPI0S30 is used as CS0n and EPI0S27 is used as CS1n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map. This configuration can be used for a RAM bank split between 2 devices as well as when using both an external RAM and an external peripheral.
0x3	ALE with Dual CSn Configuration EPI0S30 is used as address latch (ALE), EPI0S27 is used as CS1n, and EPI0S26 is used as CS0n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map.
0x4	ALE with Single CSn Configuration EPI0S30 is used as address latch (ALE) and EPI0S27 is used as CSn.
0x5	Quad CSn Configuration EPI0S30 is used as CS0n and EPI0S27 is used as CS1n. EPI0S34 is used as CS2n and EPI0S33 is used as CS3n.
0x6	ALE with Quad CSn Configuration EPI0S30 is used as ALE, EPI0S26 is CS0n, and EPI0S27 is used as CS1n. EPI0S34 is used as CS2n and EPI0S33 is used as CS3n.
0x7	Reserved

Bit/Field	Name	Type	Reset	Description
26	CSBAUD	RW	0	<p>Chip Select Baud Rate and Multiple Sub-Mode Configuration enable</p> <p>This bit is only valid when the CSCFGEXT + CSCFG field is programmed to 0x2 or 0x3, 0x5 or 0x6. This bit configures the baud rate settings for CS0n, CS1n, CS2n, and CS3n.</p> <p>This bit must also be set to allow different sub-mode configurations on chip-selects. If this bit is clear, all chip-select sub-modes are based on the MODE encoding defined in the EPI8HBCFG register.</p> <p>If the CSBAUD bit is set in the EPIHBnCFG2 register and dual- or quad-chip selects are enabled, then the individual chip selects can use different clock frequencies, wait states and strobe polarity.</p>
Value Description				
0 Same Baud Rate and Same Sub-Mode				
<p>All CSn use the baud rate for the external bus that is defined by the COUNT0 field in the EPIBAUD register and the sub-mode programmed in the MODE field of the EPIHB8CFG register.</p>				
1 Different Baud Rates				
<p>CS0n uses the baud rate for the external bus that is defined by the COUNT0 field in the EPIBAUD register. CS1n uses the baud rate defined by the COUNT1 field in the EPIBAUD register.</p> <p>CS2n uses the baud rate for the external bus that is defined by the COUNT0 field in the EPIBAUD2 register. CS3n uses the baud rate defined by the COUNT1 field in the EPIBAUD2 register.</p> <p>In addition, the sub-modes for each chip select are individually programmed in their respective EPIHB8CFGn registers.</p>

Register 9: EPI Host-Bus 16 Configuration 2 (EPIHB16CFG2), offset 0x014

Important: The MODE field in the **EPICFG** register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access **EPIHB16CFG2**, the MODE field must be 0x3.

This register is used to configure operation while in Host-Bus 16 mode. Note that this register is reset when the MODE field in the **EPICFG** register is changed. If another mode is selected and the Host-Bus 16 mode is selected again, the values must be reinitialized.

0	CSCFG bit field is used in chip select configuration.									
1	The CSCFG bit field is extended with CSCFGEXT representing the MSB.									

Table 11-15. CSCFGEXT + CSCFG Encodings

Value	Description
0x0	ALE Configuration EPIOS30 is used as an address latch (ALE). The ALE signal is generally used when the address and data are muxed (MODE field in the EPIHB16CFG register is 0x0). The ALE signal is used by an external latch to hold the address through the bus cycle.
0x1	CSn Configuration EPIOS30 is used as a Chip Select (CSn). When using this mode, the address and data are generally not muxed (MODE field in the EPIHB16CFG register is 0x1). However, if address and data muxing is needed, the WR signal (EPIOS29) and the RD signal (EPIOS28) can be used to latch the address when CSn is low.
0x2	Dual CSn Configuration EPIOS30 is used as CS0n and EPIOS27 is used as CS1n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map. This configuration can be used for a RAM bank split between 2 devices as well as when using both an external RAM and an external peripheral.
0x3	ALE with Dual CSn Configuration EPIOS30 is used as address latch (ALE), EPIOS27 is used as CS1n, and EPIOS26 is used as CS0n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map.
0x4	ALE with Single CSn Configuration EPIOS30 is used as address latch (ALE) and EPIOS27 is used as CSn.
0x5	Quad CSn Configuration EPIOS30 is used as CS0n and EPIOS27 is used as CS1n. EPIOS34 is used as CS2n and EPIOS33 is used as CS3n.
0x6	ALE with Quad CSn Configuration EPIOS30 is used as ALE, EPIOS26 is CS0n, and EPIOS27 is used as CS1n. EPIOS34 is used as CS2n and EPIOS33 is used as CS3n.
0x7	Reserved

Bit/Field	Name	Type	Reset	Description
26	CSBAUD	RW	0	<p>Chip Select Baud Rate and Multiple Sub-Mode Configuration enable</p> <p>This bit is only valid when the <code>CSCFGEXT + CSCFG</code> field is programmed to 0x2 or 0x3, 0x5 or 0x6. This bit configures the baud rate settings for CS0n, CS1n, CS2n, and CS3n.</p> <p>This bit must also be set to allow different sub-mode configurations on chip-selects. If this bit is clear, all chip-select sub-modes are based on the <code>MODE</code> encoding defined in the EPI8HBCFG register.</p> <p>If the <code>CSBAUD</code> bit is set in the EPIHBnCFG2 register and dual- or quad-chip selects are enabled, then the individual chip selects can use different clock frequencies, wait states and strobe polarity.</p>
Value Description				
0 Same Baud Rate and Same Sub-Mode				
<p>All CSn use the baud rate for the external bus that is defined by the <code>COUNT0</code> field in the EPIBAUD register and the sub-mode programmed in the <code>MODE</code> field of the EPIHB16CFG register.</p>				
1 Different Baud Rates				
<p>CS0n uses the baud rate for the external bus that is defined by the <code>COUNT0</code> field in the EPIBAUD register. CS1n uses the baud rate defined by the <code>COUNT1</code> field in the EPIBAUD register.</p> <p>CS2n uses the baud rate for the external bus that is defined by the <code>COUNT0</code> field in the EPIBAUD2 register. CS3n uses the baud rate defined by the <code>COUNT1</code> field in the EPIBAUD2 register.</p> <p>In addition, the sub-modes for each chip select are individually programmed in their respective EPIHB16CFGn registers.</p>

Register 10: EPI Address Map (EPIADDRMAP), offset 0x01C

This register enables address mapping. The EPI controller can directly address memory and peripherals. In addition, the EPI controller supports address mapping to allow indirect accesses in the External RAM and External Peripheral areas.

If the external device is a peripheral, including a FIFO or a directly addressable device, the `EPSZ` and `EPADR` bit fields should be configured for the address space. If the external device is SDRAM, SRAM, or NOR Flash memory, the `ERADR` and `ERSZ` bit fields should be configured for the address space.

If one of the dual chip select modes is selected (`CSCFGEXT` is 0x0 and `CSCFG` is 0x2 or 0x3 in the **EPIHBnCFG2** register), both chip selects can share the peripheral or the memory space, or one chip select can use the peripheral space and the other can use the memory space. In the **EPIADDRMAP** register, if the `EPADR` field is not 0x0, the `ECADR` field is 0x0, and the `ERADR` field is 0x0, then the address specified by `EPADR` is used for both chip selects, with `CS0n` being asserted when the MSB of the address range is 0 and `CS1n` being asserted when the MSB of the address range is 1. If the `ERADR` field is not 0x0, the `ECADR` field is 0x0, and the `EPADR` field is 0x0, then the address specified by `ERADR` is used for both chip selects, with the MSB performing the same delineation. If both the `EPADR` and the `ERADR` are not 0x0 and the `ECADR` field is 0x0, then `CS0n` is asserted for either address range defined by `EPADR` and `CS1n` is asserted for either address range defined by `ERADR`. The two chip selects can also be shared between the code space and memory or peripheral space. If the `ECADR` field is 0x1, `ERADR` field is 0x0, and the `EPADR` field is not 0x0, then `CS0n` is asserted for the address range defined by `ECADR` and `CS1n` is asserted for either address range defined by `EPADR`. If the `ECADR` field is 0x1, `EPADR` field is 0x0, and the `ERADR` field is not 0x0, then `CS0n` is asserted for the address range defined by `ECADR` and `CS1n` is asserted for either address range defined by `ERADR`.

If one of the Quad-Chip-Select modes is selected (`CSCFGEXT` is 0x1 and `CSCFG` is 0x2 or 0x3 in the **EPIHBnCFG2** register), both the peripheral and the memory space must be enabled. In the **EPIADDRMAP** register, the `EPADR` field is 0x3, the `ERADR` field is 0x3, and the `ECADR` field is 0x0. In this case, `CS0n` maps to 0x6000.0000; `CS1n` maps to 0x8000.0000; `CS2n` maps to 0xA000.0000; and `CS3n` maps to 0xC000.0000. The `MODE` field of the **EPIHBnCFGn** registers configures the interface for the individual chip selects, which support ADMUX or ADNOMUX. If the `CSBAUD` bit is clear, all chip selects use the mode configured in the `MODE` bit field of the **EPIHBnCFG** register. Table 11-5 on page 857 gives a detailed explanation of chip select address range mappings based on which combinations of peripheral and memory space are enabled.

Register 11: EPI Read Size 0 (EPIRSIZE0), offset 0x020**Register 12: EPI Read Size 1 (EPIRSIZE1), offset 0x030**

This register selects the size of transactions when performing non-blocking reads with the **EPIRPSTDn** registers. This size affects how the external address is incremented.

The SIZE field must match the external data width as configured in the **EPIHBNCFG** or **EPIGPCFG** register.

SDRAM mode uses a 16-bit data interface. If SIZE is 0x1, data is returned on the least significant bits (D[7:0]), and the remaining bits D[31:8] are all zeros, therefore the data on bits D[15:8] is lost. If SIZE is 0x2, data is returned on the least significant bits (D[15:0]), and the remaining bits D[31:16] are all zeros.

Note that changing this register while a read is active has an unpredictable effect.

Register 13: EPI Read Address 0 (EPIRADDR0), offset 0x024**Register 14: EPI Read Address 1 (EPIRADDR1), offset 0x034**

This register holds the current address value. When performing non-blocking reads via the **EPIRPSTDn** registers, this register's value forms the address (when used by the mode). That is, when an **EPIRPSTDn** register is written with a non-0 value, this register is used as the first address. After each read, it is incremented by the size specified by the corresponding **EPIRSIZEn** register. Thus at the end of a read, this register contains the next address for the next read. For example, if the last read was 0x20, and the size is word, then the register contains 0x24. When a non-blocking read is cancelled, this register contains the next address that would have been read had it not been cancelled. For example, if reading by bytes and 0x103 had been read but not 0x104, this register contains 0x104. In this manner, the system can determine the number of values in the NBRFIFO to drain.

Note that changing this register while a read is active has an unpredictable effect due to race condition.

Bit/Field Name Type Reset Description

31:0	ADDR	RW	0x0000.0000	Current Address Next address to read.
------	------	----	-------------	--

Register 15: EPI Non-Blocking Read Data 0 (EIPRPSTD0), offset 0x028**Register 16: EPI Non-Blocking Read Data 1 (EIPRPSTD1), offset 0x038**

This register sets up a non-blocking read via the external interface. A non-blocking read is started by writing to this register with the count (other than 0). Clearing this register terminates an active non-blocking read as well as cancelling any that are pending. This register should always be cleared before writing a value other than 0; failure to do so can cause improper operation. Note that both NBR channels can be enabled at the same time, but NBR channel 0 has the highest priority and channel 1 does not start until channel 0 is finished.

The first address is based on the corresponding **EPIRADDRn** register. The address register is incremented by the size specified by the **EPIRSIZEn** register after each read. If the size is less than a word, only the least significant bits of data are filled into the NBRFIFO; the most significant bits are cleared.

Note that all three registers may be written using one STM instruction, such as with a structure copy in C/C++.

The data may be read from the **EPIREADFIFO** register after the read cycle is completed. The interrupt mechanism is normally used to trigger the FIFO reads via ISR or µDMA.

If the countdown has not reached 0 and the NBRFIFO is full, the external interface waits until a NBRFIFO entry becomes available to continue.

Note: if a blocking read or write is performed through the address mapped area (at 0x6000.0000 through 0xDFFF.FFFF), any current non-blocking read is paused (at the next safe boundary), and the blocking request is inserted. After completion of any blocking reads or writes, the non-blocking reads continue from where they were paused.

The other way to read data is via the address mapped locations (see the **EPIADDRMAP** register), but this method is blocking (core or µDMA waits until result is returned).

To cancel a non-blocking read, clear this register. To make sure that all values read are drained from the NBRFIFO, the **EPISTAT** register must be consulted to be certain that bits **NBRBUSY** and **ACTIVE** are cleared. One of these registers should not be cleared until either the other **EIPRPSTDn** register becomes active or the external interface is not busy. At that point, the corresponding **EPIRADDRn** register indicates how many values were read.

EPI Non-Blocking Read Data n (EIPRPSTDn)

Base 0x400D.0000

Offset 0x028

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:13	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
12:0	POSTCNT	RW	0x000	<p>Post Count</p> <p>A write of a non-zero value starts a read operation for that count. Note that it is the software's responsibility to handle address wrap-around.</p> <p>Reading this register provides the current count.</p> <p>A write of 0 cancels a non-blocking read (whether active now or pending).</p> <p>Prior to writing a non-zero value, this register must first be cleared.</p>

Register 17: EPI Status (EPISTAT), offset 0x060

This register indicates which non-blocking read register is currently active; it also indicates whether the external interface is busy performing a write or non-blocking read (it cannot be performing a blocking read, as the bus would be blocked and as a result, this register could not be accessed).

This register is useful to determining which non-blocking read register is active when both are loaded with values and when implementing sequencing or sharing.

This register is also useful when canceling non-blocking reads, as it shows how many values were read by the canceled side.

Register 18: EPI Read FIFO Count (EPIRFIFOCNT), offset 0x06C

This register returns the number of values in the NBRFIFO (the data in the NBRFIFO can be read via the **EPIREADFIFO** register). A race is possible, but that only means that more values may come in after this register has been read.

EPI Read FIFO Count (EPIRFIFOCNT)

Base 0x400D.0000

Offset 0x06C

Type RO, reset -

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	COUNT	RO	-	FIFO Count Number of filled entries in the NBRFIFO.

Register 19: EPI Read FIFO (EPIREADFIFO0), offset 0x070**Register 20: EPI Read FIFO Alias 1 (EPIREADFIFO1), offset 0x074****Register 21: EPI Read FIFO Alias 2 (EPIREADFIFO2), offset 0x078****Register 22: EPI Read FIFO Alias 3 (EPIREADFIFO3), offset 0x07C****Register 23: EPI Read FIFO Alias 4 (EPIREADFIFO4), offset 0x080****Register 24: EPI Read FIFO Alias 5 (EPIREADFIFO5), offset 0x084****Register 25: EPI Read FIFO Alias 6 (EPIREADFIFO6), offset 0x088****Register 26: EPI Read FIFO Alias 7 (EPIREADFIFO7), offset 0x08C**

Important: This register is read-sensitive. See the register description for details.

This register returns the contents of the NBRFIFO or 0 if the NBRFIFO is empty. Each read returns the data that is at the top of the NBRFIFO, and then empties that value from the NBRFIFO. The alias registers can be used with the LDMIA instruction for more efficient operation (for up to 8 registers). See *Cortex™-M3/M4 Instruction Set Technical User's Manual* (literature number [SPMU159](#)) for more information on the LDMIA instruction.

EPI Read FIFn (EPIREADFIFO_n)

Base 0x400D.0000

Offset 0x070

Type RO, reset -

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	DATA	RO	-	Reads Data
------	------	----	---	------------

This field contains the data that is at the top of the NBRFIFO. After being read, the NBRFIFO entry is removed.

Register 27: EPI FIFO Level Selects (EPIFIFOLVL), offset 0x200

This register allows selection of the FIFO levels which trigger an interrupt to the interrupt controller or, more efficiently, a DMA request to the µDMA. The NBRFIFO select triggers on fullness such that it triggers on match or above (more full) in order for the processor or the µDMA to extract the read data. The WFIFO triggers on emptiness such that it triggers on match or below (less entries) in order for the processor or the µDMA to insert more write data.

It should be noted that the FIFO triggers are not identical to other such FIFOs in TM4C129XKCZAD peripherals. In particular, empty and full triggers are provided to avoid wait states when using blocking operations.

The settings in this register are only meaningful if the µDMA is active or the interrupt is enabled.

Additionally, this register allows protection against writes stalling and notification of performing blocking reads which stall for extra time due to preceding writes. The two functions behave in a non-orthogonal way because read and write are not orthogonal.

The write error bit configures the system such that an attempted write to an already full WFIFO abandons the write and signals an error interrupt to prevent accidental latencies due to stalling writes.

The read error bit configures the system such that after a read has been stalled due to any preceding writes in the WFIFO, the error interrupt is generated. Note that the excess stall is not prevented, but an interrupt is generated after the fact to notify that it has happened.

EPI FIFO Level Selects (EPIFIFOLVL)

Base 0x400D.0000
Offset 0x200
Type RW, reset 0x0000.0033

Bit/Field	Name	Type	Reset	Description
31:18	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
17	WFERR	RW	0	Write Full Error
	Value	Description		
0	The Write Full error interrupt is disabled. Writes are stalled when the WFIFO is full until a space becomes available but an error is not generated. Note that the Cortex-M3 write buffer may hide that stall if no other memory transactions are attempted during that time.			
1	This bit enables the Write Full error interrupt (WTFULL in the EPIEISC register) to be generated when a write is attempted and the WFIFO is full. The write stalls until a WFIFO entry becomes available.

Register 28: EPI Write FIFO Count (EPIWFIFOCNT), offset 0x204

This register contains the number of slots currently available in the WFIFO. This register may be used for polled writes to avoid stalling and for blocking reads to avoid excess stalling (due to undrained writes). An example use for writes may be:

```
for (idx = 0; idx < cnt; idx++) {
    while (EPIWFIFOCNT == 0) ;
    *ext_ram = *mydata++;
}
```

The above code ensures that writes to the address mapped location do not occur unless the WFIFO has room. Although polling makes the code wait (spinning in the loop), it does not prevent interrupts being serviced due to bus stalling.

EPI Write FIFO Count (EPIWFIFOCNT)

Base 0x400D.0000

Offset 0x204

Type RO, reset 0x0000.0004

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	WTAV	RO	0x4	Available Write Transactions The number of write transactions available in the WFIFO. When clear, a write is stalled waiting for a slot to become free (from a preceding write completing).

Register 29: EPI DMA Transmit Count (EPIDMATXCNT), offset 0x208

This register is used to program the total number of transfers (byte, halfword or word) by the µDMA to WRFIFO. As each transfer is processed by the EPI, the TXCNT bit field value is decreased by 1. When TXCNT = 0, the EPI's uDMA request signal is deasserted.

EPI DMA Transmit Count (EPIDMATXCNT)

Base 0x400D.0000
Offset 0x208
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TXCNT	RW	0x0000	DMA Count This field is used to program the total number of transfers (byte, halfword or word) from the µDMA to the EPI WRFIFO.

Register 30: EPI Interrupt Mask (EPIIM), offset 0x210

This register is the interrupt mask set or clear register. For each interrupt source (read, write, and error), a mask value of 1 allows the interrupt source to trigger an interrupt to the interrupt controller; a mask value of 0 prevents the interrupt source from triggering an interrupt.

EPI Interrupt Mask (EPIIM)

Base 0x400D.0000
Offset 0x210
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
1	RDIM	RW	0	Read FIFO Full Interrupt Mask Value Description 0 RDRIS in the EPIRIS register is masked and does not cause an interrupt. 1 RDRIS in the EPIRIS register is not masked and can trigger an interrupt to the interrupt controller.
0	ERRIM	RW	0	Error Interrupt Mask Value Description 0 ERRIS in the EPIRIS register is masked and does not cause an interrupt. 1 ERRIS in the EPIRIS register is not masked and can trigger an interrupt to the interrupt controller.

Register 31: EPI Raw Interrupt Status (EPIRIS), offset 0x214

This register is the raw interrupt status register. On a read, it gives the current state of each interrupt source. A write has no effect.

Note that raw status for read and write is set or cleared based on FIFO fullness as controlled by **EPIFIFOLVL**.

Raw status for error is held until the error is cleared by writing to the **EPIEISC** register.

EPI Raw Interrupt Status (EPIRIS)

1	A WFIFO Full, a Read Stalled, or a Timeout error has occurred.									

Register 32: EPI Masked Interrupt Status (EPIMIS), offset 0x218

This register is the masked interrupt status register. On read, it gives the current state of each interrupt source (read, write, and error) after being masked via the **EPIIM** register. A write has no effect.

The values returned are the ANDing of the **EPIIM** and **EPIRIS** registers. If a bit is set in this register, the interrupt is sent to the interrupt controller.

EPI Masked Interrupt Status (EPIMIS)

Value	Description									
0	An error has not occurred or the interrupt is masked.									
1	A WFIFO Full, a Read Stalled, or a Timeout error has occurred and the ERIM bit in the EPIIM register is set, triggering an interrupt to the interrupt controller.									

Register 33: EPI Error and Interrupt Status and Clear (EPIEISC), offset 0x21C

This register is used to clear a pending error interrupt. Clearing any defined bit in the **EPIEISC** has no effect; setting a bit clears the error source and the raw error returns to 0. When any of bits[2:0] of this register are read as set, it indicates that the **ERRRIS** bit in the **EPIRIS** register is set and an EPI controller error is sent to the interrupt controller if the **ERIM** bit in the **EPIIM** register is set. If any of bits [2:0] are written as 1, the register bit being written to, as well as the **ERRIS** bit in the **EPIRIS** register and the **ERIM** bit in the **EPIIM** register are cleared. If the **DMAWRIC** or **DMARDIC** bit in this register is set, then the corresponding bit in the **EPIRIS** and **EPIMIS** register is cleared. Note that writing to this register and reading back immediately (pipelined by the processor) returns the old register contents. One cycle is needed between write and read.

Register 46: EPI Host-Bus PSRAM (EPIHBPSRAM), offset 0x360

This register holds the PSRAM configuration register value. When the WRCRE bit in the **EPIHB16CFGn** register is set, all 21 bits of the **EPIHBPSRAM** register's CR value are written to the PSRAM's configuration register. When the RDCRE bit is set in the **EPIHB16CFGn** register, a read of the PSRAM's configuration register takes place and the value is written to bits[15:0] of the **EPIHBPSRAM**. Bits[20:16] will not contain any valid data.

EPI Host-Bus PSRAM (EPIHBPSRAM)

Base 0x400D.0000

Offset 0x360

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:21	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20:0	CR	RW	0x000000	PSRAM Config Register During a configuration write, all 21 bits of the CR bit field are written to the PSRAM. During configuration reads, CR bits[15:0] of this register contain the configuration read of the PSRAM. CR [20 : 16] will not contain valid data.

12 Cyclical Redundancy Check (CRC)

The Cyclical Redundancy Check (CRC) computation module can be used for message transfer and safety system checks, as well as in conjunction with the AES and DES modules. The following features are supported:

- Support four major CRC forms:
 - CRC16-CCITT as used by CCITT/ITU X.25
 - CRC16-IBM as used by USB and ANSI
 - CRC32-IEEE as used by IEEE802.3 and MPEG2
 - CRC32C as used by G.Hn
- Allows word and byte feed
- Supports auto-initialization and manual initialization
- Supports MSb and LSb
- Supports CCITT post-processing
- Can be fed by µDMA, Flash memory and code

12.1 Functional Description

The following sections describe the features of CRC.

12.1.1 CRC Support

The purpose of the CRC engine is to accelerate CRC and TCP checksum operation. The result of the CRC operation is a 32- and 16-bit signature which can be used to check the sanity of data. The required mode of operation is selected through the **TYPE** bit in the **CRC Control (CRCCTRL)** register, offset 0x400. A µDMA software channel can be used to burst data into the CRC module. CRCs are computed combinatorially in one clock.

The CRC module contains all of the control registers to which the input context interfaces. Because CRC calculations are a single cycle, as soon as data is written to **CRC Data Input (CRCDIN)** register, the result of CRC/CSUM is updated in the **CRC SEED/Context (CRCSEED)** register, offset 0x410. The input data is computed by the selected CRC polynomial or CSUM.

12.1.1.1 CRC Checksum engine

Software can offload the CRC and checksum task to the CRC checksum engine accelerator. The accelerator has registers that need to be programmed to initiate processing. These registers should be fed with data in order to calculate CRC/CSUM. Software should configure the µDMA channel for data movement through the **DMA Channel Map Select n (DMACHMAPn)** register in the µDMA module. Further µDMA configuration guidelines are available in the “Micro Direct Memory Access (µDMA)” on page 705.

The starting seed for the CRC and checksum operation is programmed in the **CRC SEED/Context (CRCSEED)** register at offset 0x410. Depending on the encoding of the **INIT** field in the **CRCCTRL** register, the value of the **SEED** field can initialized to any one of the following:

- A unique context value written to the **CRCSEED** register (`INIT=0x0`)
- All 0s (`INIT=0x2`)
- All 1s (`INIT=0x3`)

Once the operation is done, software should read the result from the **CRC Post Processing Result (CRCRSLTPP)** register, offset 0x418, and a software channel µDMA interrupt should be used to identify completion.

12.1.1.2 Data Size

The CRC module supports data being fed 32-bit words and 8 bits at a time and can dynamically switch back and forth. The data size is configured by programming the `SIZE` bit in the **CRCCTRL** register, offset 0x400.

Because CRC is a division on a long stream of bits, the application must take into consideration the bit order. When processing message data that is read out by words, bit order is not an issue. For example, if the data value in the message is 0x12345678, the most significant eight byte is 0x12 (00010010 in binary). If the data is processed as bytes, 0x12, 0x34, 0x56, and 0x78 are copied into memory in that order and the word is stored as 0x78563412, where 0x12 is written as byte 0, 0x34 is written as byte 1, and so on.

12.1.1.3 Endian Configuration

The following endian configuration is provided by the `ENDIAN` field in the **CRCCTRL** register:

- Swap byte in half-word
- Swap half word

Input data width is four bytes, hence the configuration only affects the four-byte word. The `ENDIAN` bit field supports the following configurations, assuming the input word is {B3, B2, B1, B0}

Table 12-1. Endian Configuration

Endian Encoding	Definition	Configuration
0x0	Configuration unchanged.	{B3, B2, B1, B0}
0x1	Bytes are swapped in half-words but half-words are not swapped	{B2, B3, B0, B1}
0x2	Half-words are swapped but bytes are not swapped in half-word.	{B1, B0, B3, B2}
0x3	Bytes are swapped in half-words and half-words are swapped.	{B0, B1, B2, B3}

Bit reversal is supported by the `BR` bit in the **CRCCTRL** register. The bit reversal operation works in tandem with endian control. For example, the above table with the `BR` option set would look like this:

Table 12-2. Endian Configuration with Bit Reversal

Endian Encoding	Initial Endian Configuration	Configuration with Bit Reversal (BR = 1)
0x0	Configuration unchanged. {B3[31:24], B2[23:16], B1[15:8], B0[7:0]}	B3[24:31], B2[16:23], B1[8:15], B0[0:7]

Table 12-2. Endian Configuration with Bit Reversal (continued)

ENDIAN Encoding	Initial Endian Configuration	Configuration with Bit Reversal (BR = 1)
0x1	Bytes are swapped in half-words but half-words are not swapped {B2[23:16], B3[31:24], B0[7:0], B1[15:8]}	B2[16:23],B3[24:31],B0[0:7],B1[8:15]
0x2	Half-words are swapped but bytes are not swapped in half-word. {B1[15:8], B0[7:0], B3[31:24], B2[23:16]}	B1[8:15],B0[0:7],B3[24:31],B2[16:23]
0x3	Bytes are swapped in half-words and half-words are swapped {B0[7:0], B1[15:8], B2[23:16], B3[31:24]}	B0[0:7],B1[8:15],B2[16:23],B3[24:31]

12.2 Initialization and Configuration

The following describes the initialization and configuration procedures of the CRC module.

12.2.1 CRC Initialization and Configuration

The CRC engine works in push through mode, which means it works on streaming data. This section describes the steps for initializing the CRC module:

1. Enable the CRC by setting the R0 bit in the CRC and Cryptographic Modules (RCGCCM) register, System Control offset 0x674.
2. Configure the desired CRC data size, bit order, endian configuration and CRC type by programming the **CRC Control (CRCCTRL)** register, offset 0x400.
3. If the CRC value has not been initialized to all 0s or all 1s using the INIT field in the **CRCCTRL** register, program the initial value in the **CRC SEED/Context (CRCSEED)** register, offset 0x410.
4. Repeatedly write the DATAIN field in the **CRC Data Input (CRCDIN)** register, offset 0x414. If the SIZE bit in the **CRCCTRL** register is set to select byte, the CRC engine operates in byte mode and only the least significant byte is used for CRC calculation.
5. When CRC is finished, read the **CRCSEED** register for the final result. If using post-processing, the raw CRC result is stored in the **CRCSEED** register and the final, post-processed result can be read from the **CRC Post-Processing Result (CRCRSLTPP)** register, offset 0x418. Post-processing options are selectable through the OBR and OLNV bits of the **CRCCTRL** register.

Alternatively a software µDMA channel can be configured to copy data from the source into the **CRCDIN** register. When configuring the µDMA, the destination should be configured to not increment. For more information on how to configure the µDMA, refer to “Micro Direct Memory Access (µDMA)” on page 705.

12.2.1.1 Data Endian Convention for the CRC Engine

If the input stream is expressed as a byte stream, Din, where $Din = \{D0, D1, D2, D3, D4, D5, D6, D7, D8, D9, D11, D12, D13, D14, D15, D16, \dots\}$, then data should be fed to the CRC engine as follows:

- If operating in Byte mode, the **CRCDIN** register should be written in the following order:
 1. {00, 00, 00, D0}

2. {00, 00, 00, D1}
 3. {00, 00, 00, D2}
 4. {00, 00, 00, D3}
 5. {00, 00, 00, D4}
 6. {00, 00, 00, D5}
 7. {00, 00, 00, D6}
 8.
 9.
- If operating in word mode, the **CRCDIN** register should be written in the following order:
 1. {D3, D2, D1, D0}
 2. {D7, D6, D5, D4}
 3. {D11, D10, D9, D8}
 4.
 5.

12.3 Register Map

Table 12-3 on page 978 lists the CRC Module registers. The offset listed is a hexadecimal increment to the register's address, relative to the base address 0x4403.0000.

Table 12-3. CCM Register Map

Offset	Name	Type	Reset	Description	See page
0x400	CRCCTRL	RW	0x0000.0000	CRC Control	979
0x410	CRCSEED	RW	0x0000.0000	CRC SEED/Context	981
0x414	CRCDIN	RW	0x0000.0000	CRC Data Input	982
0x418	CRCRSLTPP	RO	0x0000.0000	CRC Post Processing Result	983

12.4 CRC Module Register Descriptions

This section lists and describes the CRC registers, in numerical order by address offset.

Note: The CRC module can only be accessed through privileged mode. If the µDMA is used for CRC transfers, then the µDMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

Register 1: CRC Control (CRCCTRL), offset 0x400

The **CRC Control (CRCCTRL)** register is used to configure control of the CRC.

Register 2: CRC SEED/Context (CRCSEED), offset 0x410

The **CRC SEED/Context (CRCSEED)** register is initially written with one of the following three values depending on the encoding of the INIT field in the **CRCCTRL** register:

- The context value written to the **CRCSEED** register. This encoding is for SEED values from a previous CRC calculation or a specific protocol. (INIT=0x0)
- 0x0000.0000 (INIT=0x2)
- 0x1111.1111 (INIT=0x3)

CRC SEED/Context (CRCSEED)

Base 0x4403.0000
Offset 0x410
Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0 SEED RW 0x0000.0000 SEED/Context Value

This register contains the starting seed of the CRC and checksum operation. This register also holds the latest result of CRC or checksum operation.

Register 3: CRC Data Input (CRCDIN), offset 0x414

The application or µDMA writes the **CRC Data Input (CRCDIN)** register with the next byte or word to compute.

CRC Data Input (CRCDIN)

Base 0x4403.0000
Offset 0x414
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	DATAIN	RW	0x0000.0000	This register contains the input data value for the CRC or checksum operation.

Register 4: CRC Post Processing Result (CRCRSLTPP), offset 0x418

This register contains the post-processed CRC result as configured by the **CRCCTRL** register.

CRC Post Processing Result (CRCRSLTPP)

Base 0x4403.0000

Offset 0x418

Type RO, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0 RSLTPP RO 0x0000.0000 Post Processing Result

This register contains the post-processed CRC result.

13 Advance Encryption Standard Accelerator (AES)

This section describes the Advanced Encryption Standard (AES) cryptographic hardware-accelerated module.

13.1 AES Overview

This section introduces the AES and describes the AES main functions and connections in the device.

The advanced encryption standard (AES) security modules provide hardware-accelerated data encryption and decryption operations based on a binary key. The AES is a symmetric cipher module that supports a 128-bit, 192-bit, or 256-bit key in hardware for both encryption and decryption. The AES module is based on a symmetric algorithm, meaning that the encryption and decryption keys are identical. To encrypt data means to convert it from plain text to an unintelligible form called cipher text. Decrypting cipher text converts previously encrypted data back to its original plain text form.

The main features of the AES accelerator are:

- Support for basic AES encrypt and decrypt operations:
 - Galois/Counter Mode (GCM), with basic GHASH operation
 - Counter Mode with CBC-MAC (CCM)
 - XTS Mode
- Availability of the following feedback operating modes:
 - Electronic Code Book Mode (ECB)
 - Cipher Block Chaining Mode (CBC)
 - Counter Mode (CTR)
 - Cipher Feedback Mode (CFB), 128-bit
 - F8 Mode
- Key sizes 128-, 192- and 256-bits
- Support for CBC_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for µDMA transfers
- Fully synchronous design

13.2 AES Functional Description

The following sections describe the features of the AES Module.

13.2.1 AES Block Diagram

Figure 13-1 on page 985 shows the AES block diagram. A single-core/dual-interface architecture is used.

Figure 13-1. AES Block Diagram

AES is an efficient implementation of the Rijndael cipher (the AES algorithm) and a 128-bit polynomial multiplication (referred to here as GHASH, as per the AES-GCM specification). Rijndael is a block cipher in which each data block is 128 bits. The polynomial multiplication multiplies two 128-bit vectors using the smallest 128-bit irreducible polynomial, represented by the following 128-bit string: {0¹²⁰}||10000111. The two implementations are combined into the AES wide-bus engine.

Depending on the availability of context and data, the AES wide-bus engine is automatically triggered to process the data. The AES wide-bus engine is directly connected to the context and data registers so that it can immediately start processing when all data is available. The AES wide-bus engine also interfaces to the I/O Control FSM/μDMA Request Interface.

AES comprises the following major functional blocks:

- Global control FSM and μDMA interface
- Register interface module
- The AES wide-bus engine

The AES wide-bus engine, which is the major top-level component, comprises the following functional blocks:

- Mode control FSM: Manages the data flow to and from the AES wide-bus engine and starts each encryption/decryption operation.

- Feedback modes: The logic that implements the various feedback modes supported by AES.
- GHASH core: The polynomial multiplication algorithm used for AES-GCM
- AES key scheduler: Generates AES encryption and decryption (round) keys
- AES encryption core: The AES encryption algorithm
- AES decryption core: The AES decryption algorithm
- Substitution-boxes (S-Boxes): Contain AES S-Box GF(2⁸) implementations

AES encryption requires a specific number of rounds, depending on the key length. The supported key lengths are 128-, 192-, and 256-bit, which require 10, 12, and 14 rounds, respectively, or 32, 38, and 44 clock cycles, respectively, because {number of clock cycles} = 2 + 3 x {number of rounds}.

The larger key lengths provide greater encryption strength at the expense of additional rounds and therefore reduced throughput. The overall throughput of the AES executing polynomial multiplication is adjusted based on the overall cryptographic performance. The AES module contains one Electronic Codebook (ECB) core and a dedicated 32-cycle polynomial multiplication module for performing GHASH operations. Polynomial multiplication operates in parallel with the AES core, if data is available for both modules.

Depending on the key size (128/192/256 bits), this core requires 32, 38, or 44 clock cycles to process one 128-bit data block. While one data block processes, the next block can be preloaded immediately. When a block is preloaded, the previous block must finish before additional data can be loaded. Therefore, once the pipeline is full, sequential data blocks can be passed every 32, 38, or 44 clock cycles.

13.2.1.1 Interfaces

The interface signals to the AES module can be grouped into the following four categories:

- Clock and reset signals
- Register interface
- μDMA/INT interface, used to request new context and packet data or to indicate available result data (encrypted/decrypted data or authentication result)

13.2.1.2 Register Interface

The register interface block performs all address decoding and control. However, not all registers are located in this block. The context and data input registers are in the AES wide-bus engine. The data output registers are available in this block.

13.2.1.3 AES Wide-Bus Engine

The AES wide-bus engine performs the cryptographic operations. The composition of the AES core is:

- The main data path operates on the input block, performing the required substitution, shift, and mix operations.
- The key scheduler generates the round keys. A new subkey is generated and XORed with the data each round.

AES Key Scheduler

The AES key scheduler generates the round keys. During each round, a new subkey is generated from the input key to be XORed with the data. Round keys are generated on-the-fly and parallel to data processing to minimize register requirements.

For encryption operations, the key sequencer transfers the initial key data to the AES core. For decryption operations, the key scheduler must provide the final subkey to the AES core so it can generate the subkeys in reverse order.

AES Encryption Core

The AES encryption core implements the Rijndael algorithm as specified in [FIPS-197]. This core operates on the input block and performs the required substitution, shift, and mix operations. For each round, the encryption core receives the proper round key from the AES key scheduler. A fundamental component of the AES algorithm is the S-Box. The S-Box provides a unique 8-bit output for each 8-bit input. This implementation of the AES encryption core has a 64-bit data path.

AES Decryption Core

The architecture of the AES decryption core is generally the same as the architecture of the encryption core. One difference is that the generation of round keys for decryption requires an initial conversion of the input key (always supplied by the host in the form of an encryption key) to the corresponding decryption key. This conversion is done by performing a dummy encryption operation and storing the final round key as a decryption key. The key scheduler is then reversed to generate the round keys for the decryption operation. Consequently, for each sequence of decryption operations under the same key, a single throughput reduction equal to the time to encrypt a single block occurs. Once a decryption key is generated, subsequent decryption operations with the same key use this generated decryption key directly.

AES Feedback Mode Block

The AES feedback mode block buffers the feedback parameters and controls the various feedback modes. For more information about the ECB, CBC, CTR, and CFB modes of operation, see the [NIST-SP800-38A](#) specification.

CTR implements the standard incrementing function, as described in the NIST-SP800-38A specification, with m set to 16 or a multiple of 32.

AES-XTS mode requires a polynomial multiplication for initialization vector (IV) generation of the AES operation. This multiplication can be simplified when the first result is available due to the definition and use of the block number within a unit. The input for the polynomial multiplication is not directly j , but α^j , where $\alpha = x^2$ in the $GF(2^{128})$ domain.

In addition, f8 encryption/decryption mode and f9 and (X)CBC-MAC authentication modes are available.

GHASH Block

The data sequencer manages the data flow to and from the AES core. For data input, the data sequencer monitors the input buffer until a 16-byte block is available. If the AES core is idle, the data sequencer writes this data block to the internal working registers of the AES core, thus clearing the buffer for the next block.

After completing an encryption or decryption operation, the data sequencer writes the AES output to the output buffer. If the output buffer is full at the time of completion, the AES core is held until the buffer clears. Although the data sequencer is designed to support uninterrupted packet encryption, the host must properly manage the input and output packet buffers to achieve optimal performance.

13.2.2 AES Algorithm

The AES algorithm generates block ciphers. The AES block size is 16 bytes. The AES key(s) can be coded on 128, 192, or 256 bits. The larger key sizes provide a higher level of security, but at the cost of a moderate decrease in throughput.

For the AES algorithm:

- The length of the input and output blocks is 128 bits, which is represented by $Nb = 4$, which reflects the number of 32-bit words.
- The length of the cipher key (K) is 128, 192, or 256 bits. The key length is represented by $Nk = 4, 6$, or 8 , which reflects the number of 32-bit words in the cipher key.
- The number of rounds to be performed during the execution of the algorithm is dependent on the key size. The number of rounds is represented by Nr , where $Nr = 10$ when $Nk = 4$ (128-bit key); $Nr = 12$ when $Nk = 6$ (192-bit key); and $Nr = 14$ when $Nk = 8$ (256-bit key).

Table 13-1 on page 988 lists the combinations of keys, blocks, and rounds.

Table 13-1. Key-Block-Round Combinations

Key	Key Length (Nk)	Block Size (Nb)	Number of Rounds (Nr)
128 bits	4	4	10
192 bits	6	4	12
256 bits	8	4	14

The AES algorithm for cipher and inverse cipher uses a round function composed of four different byte-oriented transformations:

- Byte substitution using a substitution table (S-Box)

This transformation is a non-linear byte substitution that operates independently on each byte of the state (the state is an intermediate processed block of 128 bits inside the AES; the state is arranged as an array of [4 x Nk] bytes) using an S-Box. This S-Box transformation is reversible.

- Shifting rows of the state array by different offsets

In this transformation, the bytes in the last three rows of the state are cyclically shifted over different numbers of bytes (offsets). The first row ($r = 0$) is not shifted.

- Mixing the data within each column of the state array

This transformation operates on the state column-by-column, treating each column as a four-term polynomial. The columns are considered polynomials over $GF(2^8)$ and multiplied modulo $x^4 + 1$ with a fixed polynomial $a(x)$.

- Adding a round key to the state

In this transformation, a round key is added to the state by a simple bitwise XOR operation. Each round key consists of Nb words from the key schedule.

The AES algorithm takes the cipher key (K) and performs a key expansion routine to generate a key schedule. The key expansion generates a total of $Nb \times (Nr + 1)$ words: The algorithm requires an initial set of Nb words, and each of the Nr rounds requires Nb words of key data. The resulting key schedule consists of a linear array of 4-byte words, denoted $[w_i]$, with i in the range $0 \leq i < Nb \times (Nr + 1)$.

13.2.3 AES Operating Modes

13.2.3.1 Supported Modes of Operation

ECB Feedback Mode

Figure 13-2 on page 989 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output is passed directly to the output buffer.

For decryption, the cryptographic core operates in reverse: the decryption data path is used for data processing, whereas encryption uses the encryption data path.

Figure 13-2. AES - ECB Feedback Mode

CBC Feedback Mode

Figure 13-3 on page 990 shows the CBC feedback mode of operation, where the input data is XORed with the IV before it is passed to the basic cryptographic core. The output of the cryptographic core passes directly to the output buffer and becomes the next IV.

The operation is reversed for decryption, resulting in an XOR at the output of the cryptographic core. The input cipher text of the current operation is the IV for the next operation.

Figure 13-3. AES - CBC Feedback Mode**CTR and ICM Feedback Modes**

Figure 13-4 on page 990 shows the counter feedback (CTR/ICM) mode of operation. This operation encrypts the IV. The output of the cryptographic core (encrypted IV) is XORed with the data, thus creating the output result.

The IV is built out of two components: a fixed part and a counter part. The counter part is incremented with each block. The counter width is selectable per context and can be 16, 32, 64, 96, or 128 bits wide. In this mode, encryption and decryption use the same operation.

Figure 13-4. AES Encryption With CTR/ICM Mode

Note: The value for n can be 1, 2, 3, or 4 for CTR mode and is $\frac{1}{2}$ for ICM mode.

CFB Mode

Figure 13-5 on page 991 shows the full block (128 bits) CFB mode of operation for encryption and decryption. The input for the cryptographic core is the IV; the result is XORed with the data. The result is fed back through the IV register as the next input for the cryptographic core. The decryption operation is reversed, but the cryptographic core still performs encryption.

Figure 13-5. AES - CFB Feedback Mode

F8 Mode

Figure 13-6 on page 992 shows the F8 feedback mode of operation for encryption and decryption. The input to the cryptographic core is the result of the XOR operation of the previous cryptographic core output, a constant IV, and a block counter. The output of the cryptographic core is XORed with the input to create the result. In this mode, encryption and decryption use the same operations.

Figure 13-6. AES - F8 Mode**XTS Operation**

Figure 13-7 on page 992 shows the XTS mode of operation for encryption and decryption. The input to the cryptographic core is XORed with the IV; the output of the cryptographic core is XORed with the same IV. For decryption, the cryptographic core operates in reverse, but the XOR operations are the same.

Figure 13-7. AES - XTS Operation

Note: The IV is created with an initial encryption, followed by an LFSR operation for each new block.

F9 Operation

Figure 13-8 on page 993 shows the F9 authentication mode of operation, where the input to the cryptographic core is XORed with the IV, and the output is XORed with the previous result to create the next result. The cryptographic core output is fed back as IV for the next block. The result is the output of the last XOR operation of the cryptographic core output.

Figure 13-8. AES - F9 Operation

CBC-MAC Operation

Figure 13-9 on page 994 shows the CBC-MAC authentication mode of operation, where the input to the cryptographic core is XORed with the IV. The cryptographic core output is then fed back as IV for the next block. The last data input block is XORed with an additional input value stored in the temporary buffer; this can be any precalculated value and is dependent on the alignment of the last input block. The result is the cryptographic core output of the last encryption operation.

Figure 13-9. AES - CBC-MAC Authentication Mode**GCM Operation**

Figure 13-10 on page 995 shows one round of a GCM operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. After the encryption/decryption, the ciphertext is XORed with the intermediate authentication result. The XORed result is used as input for the polynomial multiplication to create the next (intermediate) authentication result. For more information about the GCM protocol, see the section called “GCM Protocol Operation” on page 996.

Figure 13-10. AES - GCM Operation**CCM Operation**

Figure 13-11 on page 996 shows one round of a CCM (counter with CBC-MAC) operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. Immediately after the encryption operation, the plaintext is XORed with the intermediate authentication result. The XOR result is used as input for a second encryption operation to calculate the next (intermediate) authentication result.

Figure 13-11. AES - CCM Operation

13.2.3.2 Extended and Combined Modes of Operations

This section describes the protocols (or autonomous precalculations) supported by the AES wide-bus engine.

GCM Protocol Operation

A GCM protocol operation is a combined operation consisting of encryption/decryption and authentication. A part of the input data stream can be authenticated only, while normally most of the input data is encrypted/decrypted and authenticated. The authentication-only data must always be in front of the data requiring encryption. Within GCM, the authentication-only data is called the additional authentication data (AAD). The AAD is fetched independently of other data.

The intermediate (temporary) result data is used as input to the remaining authentication operation. Because the authentication operation does not require the cryptographic core but only the polynomial multiplication, encryption/decryption and authentication can be performed in parallel. After encryption of the last data block, additional polynomial multiplication and encryption are required to authenticate a 128-bit length vector and finally encrypt the authentication result.

CCM Protocol Operation

The CCM protocol operation is a combined operation consisting of encryption/decryption and authentication. The authentication and encryption/decryption operations use the cryptographic core; these are executed sequentially on the AES core. A part of the data stream can require authentication only. The authentication-only data must always be in front of the data requiring encryption.

Authentication starts with the encryption of a predefined block B0. This block consists of flags, nonce, and message length. The next blocks contain the authentication data length concatenated with the authentication-only data. After processing the authentication-only data, the encryption/decryption operations are performed, each followed by the related authentication of the plaintext data block (which equals the input in the case of encryption, and the output in the case of

decryption). The final authentication result must be encrypted using the output of the encryption of the IV block A0. This block contains the IV (consisting of flags and nonce) concatenated with the counter, which is zero for A0.

13.2.4 AES Software Reset

To perform a software reset of the AES module, write a 1 to the SOFTRESET bit in the **AES System Configuration (AES_SYSCONFIG)** register. The RESETDONE bit in the **AES Secure System Status (AES_SYSSTATUS)** register indicates that the software reset is complete when its value is 1. When the software reset completes, the SOFTRESET bit in the **AES_SYSCONFIG** register is automatically reset. Software must ensure that the software reset completes before doing any operations.

The behavior of the software reset is the same as the hardware reset, except that the software reset bit resets this module without affecting the reset core domain of the entire device.

13.2.5 Power Management

To save power, the application can disable the clock to the AES module when not in use. The AES is clock gated by setting the AESCFG bit in the **Cryptographic Modules Clock Gating Request (CCMCGREQ)** register, CRC and Cryptographic Modules (CCM) offset 0x204. The AES in addition to the DES, SHA/MD5 and CRC can also be clock gated as a group by setting the D0 bit in the **CRC and Cryptographic Modules (DCGCCC)** register, System Control Module offset 0x874.

13.2.6 Hardware Requests

The AES module can assert a μDMA request for context in, context out, input data, or output data read. The **AES uDMA Interrupt Mask (AES_DMAIM)** register can be set to generate interrupts during the following events:

- Context In μDMA request (AES0 Cin)
- Context Out μDMA request (AES0 Cout)
- Data In μDMA request (AES0 Din)
- Data Out μDMA request (AES0 Dout)

The AES Module can be programmed to assert an interrupt when the uDMA has completed its last transfer. Please refer to “AES μDMA Interrupt Register Descriptions (CCM Offset)” on page 1029 for more information.

If context and data transfers are to be handled through software, then the **AES Interrupt Enable (AES_IRQENABLE)**, offset 0x090, can be used to enable interrupt triggering when context out, context in, data in or data out is ready. The **AES Interrupt Status (AES_IRQSTATUS)**, offset 0x08C, indicates when an interrupt is triggered.

Table 13-2. Interrupts and Events

Event	Description
AES_IRQSTATUS[3]: CONTEXT_OUT	Context output interrupt
AES_IRQSTATUS[2]: DATA_OUT	Data output interrupt
AES_IRQSTATUS[1]: DATA_IN	Data input interrupt
AES_IRQSTATUS[0]: CONTEXT_IN	Context input interrupt

13.3 AES Performance Information

Table 13-3 on page 998 lists the performance for all supported key sizes and modes of operations. It assumes that the engine is kept fully utilized (that is, the host is supplying input blocks and retrieving output blocks in such a way that the engine never has to wait for input), and that the previous output has been retrieved before the next output is ready.

Table 13-3. AES Module Performance (Input/Output Block Size = 128)

Key Size	Mode of Operation	Cycles per Block ^a	Throughput (bits/cycle)
128	ECB-encrypt / decrypt	32	4.00
	CBC-decrypt		
	CTR/ICM-encrypt / decrypt		
	CFB128-decrypt		
	CBC-encrypt		
	OFB-encrypt / decrypt		
	f8-encrypt / decrypt		3.88
	CFB128-encrypt		
	XTS-encrypt / decrypt		
	GCM-outbound / inbound		
	CCM-encrypt / decrypt	66	1.94
	CBC-MAC ^b	33	3.88
	f9 ^b		
192	ECB-encrypt / decrypt	38	3.37
	CBC-decrypt		
	CTR/ICM-encrypt / decrypt		
	CFB128-decrypt		
	CBC-encrypt	39	3.28
	OFB-encrypt / decrypt		
	f8-encrypt / decrypt		
	CFB128-encrypt		
	XTS-encrypt / decrypt		3.28
	GCM-outbound / inbound		
	CCM-encrypt / decrypt	78	1.64
	CBC-MAC ^b	39	3.28
	f9 ^b		

Table 13-3. AES Module Performance (Input/Output Block Size = 128) (continued)

Key Size	Mode of Operation	Cycles per Block ^a	Throughput (bits/cycle)
256	ECB-encrypt / decrypt	44	2.91
	CBC-decrypt		
	CTR/ICM-encrypt / decrypt		
	CFB128-decrypt		
	CBC-encrypt		
	OFB-encrypt / decrypt		
	f8-encrypt / decrypt		
	CFB128-encrypt		
	XTS-encrypt / decrypt		
	GCM-outbound inbound		
CCM-encrypt / decrypt		90	1.42
	CBC-MAC ^b	45	2.84
	f9 ^b		

a. Standard Block Size (128 bits)

b. Input Only

The "Cycles per block" numbers do not apply to the first block after selection of a new key and/or mode of operation, or the last block before switching to a new algorithm. The next table indicates the additional clock cycles; required for changing context data.

Table 13-4. AES Module Packet Mode Switch Overhead

New Context	Cycles needed for first block/and to finish the last block	Total
mode is encrypt	1 / 1	2
mode is decrypt, key size is 128	32 / 1	33
mode is decrypt, key size is 192	38 / 1	39
mode is decrypt, key size is 256	44 / 1	45
mode is XTS, key size is 128	34 / 1	35
mode is XTS, key size is 192	40 / 1	41
mode is XTS, key size is 256	46 / 1	47
outbound GCM, AES key size is 128	33 ^a / 52	85
outbound GCM, AES key size is 192	39 ^a / 52	91
outbound GCM, AES key size is 256	45 ^a / 52	97
inbound GCM, AES key size is 128	33 ^a / 27	60
inbound GCM, AES key size is 192	39 ^a / 27	66
inbound GCM, AES key size is 256	45 ^a / 27	72
outbound CCM, AES key size is 128	33 ^b / 33	66
outbound CCM, AES key size is 192	39 ^b / 39	78
outbound CCM, AES key size is 256	45 ^b / 45	90
inbound CCM, AES key size is 128	33 ^b / 33	66
inbound CCM, AES key size is 192	39 ^b / 39	78

Table 13-4. AES Module Packet Mode Switch Overhead (continued)

New Context	Cycles needed for first block/and to finish the last block	Total
inbound CCM, AES key size is 256	45 ^b / 45	90

- a. Numbers for regular GCM mode (H is precalculated and Y0-encrypted need to be calculated internally using the new IV). If H needs to be calculated by the core (complete GCM mode), this number needs to be doubled. If Y0-encrypted is not calculated (forced to zero, such that the hash result is not encrypted) this number is zero.
- b. Numbers for regular CCM mode. Dependent on the AAD length it is possible that one additional encryption needs to be done to finalize the AAD authentication; if the additional operation is required, this number needs to be doubled.

13.4 AES Module Programming Guide

13.4.1 AES Low - Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the AES Module.

13.4.1.1 Global Initialization

The following list describes the requirements for initializing the AES and surrounding modules when AES is used for the first time after a device reset.

1. When reset has completed, enable the AES by setting the R0 bit in the **CRC and Cryptographic Modules Run Mode Clock Gating Control (RCGCCCm)**, System Control offset 0x674. When the R0 bit is set in the **CRC and Cryptographic Modules Peripheral Ready (PRCCm)**, System Control offset 0xA74 register, the AES is powered and ready to be configured.
2. Configure the AES µDMA channels for Context In, Context Out, Data In, and/or Data Out by programming the appropriate encoding value in the **DMA Channel Map Select n (DMACHMAPn)** register in the µDMA module, offset 0x510. For more information on how to program channel assignments as well as enabling burst and the configured channels, refer to “Micro Direct Memory Access (µDMA)” on page 705.
3. Execute a software reset by setting the SOFTRESET bit in the **AES_SYSCONFIG** register. When reset is complete, the RESETDONE bit reads as 1 in the **AES_SYSSTATUS** register.
4. If the AES channels are configured in the µDMA, enable the required AES DMA requests by programming bits [9:5] of the **AES_SYSCONFIG** register, in addition to the completion interrupts in the **AES DMA Interrupt Mask (AES_DMAIM)** register, CCM offset 0x020.
5. Specify the size of the keys by programming the KEY_SIZE bit field in the **AES_CTRL** register.
6. Load **AES Key 1 (AES_KEY1_n)** register.
7. Load **AES Key 2 (AES_KEY2_n)** register if it is used by the configuration mode. Refer to Table 13-6 on page 1008 for information regarding which configuration modes require a load to this register.
8. Configure the AES for the appropriate encryption/decryption mode (see the section called “Subsequence: Initialize CCM AES Core Mode” on page 1001 through the section called “Subsequence: Initialize CBC AES Core Mode” on page 1002).
9. Select encryption or decryption by programming the DIRECTION bit in the **AES Control (AES_CTRL)** register, offset 0x050.

13.4.1.2 Initialization Subsequence

The following sections list the initialization subsequences for the available encryption/decryption modes:

Subsequence: Initialize CCM AES Core Mode

The CCM mode initialization is as follows:

1. Define the width of the length field and the length of the authentication field by programming the **CCM_L** and **CCM_M** bit fields in the **AES_CTRL** register at offset 0x050.
2. Enable counter mode by setting the **CTR** bit in the **AES_CTRL** register.
3. Load the authentication data length in the **AUTH** field of the **AES Authentication Data Length (AES_AUTH_LENGTH)** register at offset 0x05C.
4. Select the IV counter by programming the **CTR_WIDTH** field in the **AES_CTRL** register.
5. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize GCM AES Core Mode

The following steps to enable GCM mode is as follows:

1. Enable counter mode by setting the **CTR** bit in the **AES_CTRL** register.
2. Load the authentication data length in the **AUTH** field of the **AES Authentication Data Length (AES_AUTH_LENGTH)** register at offset 0x05C.
3. Select the IV counter by programming the **CTR_WIDTH** field in the **AES_CTRL** register.
4. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize CBC-MAC AES Core Mode

To initialize CBC-MAC Mode:

1. Enable CBC-MAC Mode by setting the **CBCMAC** bit in the **AES_CTRL** register.
2. Select encryption mode by setting the **DIRECTION** bit in the **AES_CTRL** register at offset 0x050.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize F9 AES Core Mode

The steps for configuring the AES for F9 mode is as follows:

1. Enable F9 Mode by setting the **F9** bit in the **AES_CTRL** register.
2. Set the key size to 128 bits by programming the **KEY_SIZE** field to 0x1 in the **AES_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize F8 AES Core Mode

The steps for configuring the AES for F8 mode is as follows:

1. Enable F8 Mode by setting the F8 bit in the **AES_CTRL** register.
2. Select the counter width by programming the **CTR_WIDTH** field in the **AES_CTRL** register.
3. Set the key size to 128 bits by setting the **KEY_SIZE** field to 0x1 in the **AES_CTRL** register.
4. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize XTS AES Core Mode

To initialize the AES code for XTS mode:

1. Enable XTS Mode by configuring the **XTS** field in the **AES_CTRL** register.
2. If the **XTS** field in the **AES_CTRL** register indicates that the AAD length is required, load the AAD length in the **AES_AUTH_LENGTH** register.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize CFB AES Core Mode

To initialize the AES code for CFB mode:

1. Enable CFB Mode by setting the **CFB** bit in the **AES_CTRL** register.
2. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize ICM AES Core Mode

To initialize the AES code for ICM mode:

1. Enable ICM Mode by setting the **ICM** bit in the **AES_CTRL** register.
2. Configure for a 16-bit counter by programming the **CTR_WIDTH** to 0x0 in the **AES_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize CTR AES Core Mode

To initialize CTR mode:

1. Enable CTR Mode by setting the **CTR** bit in the **AES_CTRL** register.
2. Select counter width by programming the **CTR_WIDTH** in the **AES_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

Subsequence: Initialize CBC AES Core Mode

To configure CBC mode:

1. Enable CBC Mode by setting the **MODE** bit in the **AES_CTRL** register.
2. Load the **AES Initialization Vector Input n (AES_IV_IN_n)** registers at offset 0x040 to 0x04C.

13.4.1.3 Operational Modes Configuration

AES Polling Mode

Main Sequence: AES Polling Mode

Figure 13-12 on page 1003 shows AES polling mode. The registers used in AES polling mode are:

- **AES Data RW Plaintext/Ciphertext 0 (AES_DATA_IN_0)** registers, offset 0x060 to 0x06C
- **AES Control (AES_CTRL) register**, offset 0x050
- **AES Hash Tag Out 0 (AES_TAG_OUT_0)**, offset 0x070

Figure 13-12. AES Polling Mode

AES Interrupt Mode

The application can use software interrupts to control the flow of Context In, Context Out, Data In, and Data Out requests. To enable these interrupts:

1. Once the device has been initialized, following the initialization sequences described in “Global Initialization” on page 1000 and “Initialization Subsequence” on page 1001, the application can enable the AES module interrupts through the **AES Interrupt Enable (AES_IRQENABLE)** register, offset 0x090. If all four interrupts must be enabled, the application can write 0x0000.000F to the **AES_IRQENABLE** register.

2. Load the input buffers, **AES_DATA_IN_n**, with data.

Note: If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, AES µDMA Mode should be used and the bits in the **AES_IRQENABLE** register should be cleared.

AES DMA Mode

When AES DMA Mode is enabled, the **AES_IRQENABLE** register should be cleared. To enable the µDMA to transfer data follow these steps:

1. Once the AES module has been initialized, enable the AES module µDMA channels by programming the **DMA Channel Map Select n (DMACHMAPn)** register in the µDMA module. Further µDMA configuration guidelines are available in the “Micro Direct Memory Access (µDMA)” on page 705.
2. Configure the dma_done interrupts by programming the **AES DMA Masked Interrupt Status (AES_DMAMIS)** register, at CCM offset 0x028.
3. Enable the µDMA channels in the AES by programming the µDMA enable bits in the **AES System Configuration (AES_SYSCONFIG)** register, offset 0x084.
4. The input buffer registers, **AES_DATA_IN_n**, at offsets 0x060 to 0x06C, are loaded.

13.4.1.4 AES Events Servicing

Interrupt Servicing

This section describes the event servicing of the module. Figure 13-13 on page 1005 shows the AES interrupt service. The registers used during event servicing are:

- **AES_IRQSTATUS**
- **AES_KEY1_n**
- **AES_KEY2_n**
- **AES_IV_IN_n**
- **AES_DATA_IN_n**
- **AES_TAG_OUT_n**
- **AES_IRQENABLE**

Figure 13-13. AES Interrupt Service

13.5 Register Map

Table 13-5 on page 1005 lists the AES registers. The AES Module comprises registers that exist at an offset relative to the AES Module base address and a small set of AES µDMA registers that exist at an offset relative to an Encryption Control Module base address. The AES Module register offsets are relative to the base address 0x4403.6000. The AES µDMA interrupt registers are offset relative to the base address 0x4403.0000.

13.6 AES Register Descriptions

This section lists and describes the AES registers, in numerical order by address offset.

- Register 1: AES Key 2_6 (AES_KEY2_6), offset 0x000**
- Register 2: AES Key 2_7 (AES_KEY2_7), offset 0x004**
- Register 3: AES Key 2_4 (AES_KEY2_4), offset 0x008**
- Register 4: AES Key 2_5 (AES_KEY2_5), offset 0x00C**
- Register 5: AES Key 2_2 (AES_KEY2_2), offset 0x010**
- Register 6: AES Key 2_3 (AES_KEY2_3), offset 0x014**
- Register 7: AES Key 2_0 (AES_KEY2_0), offset 0x018**
- Register 8: AES Key 2_1 (AES_KEY2_1), offset 0x01C**
- Register 9: AES Key 1_6 (AES_KEY1_6), offset 0x020**
- Register 10: AES Key 1_7 (AES_KEY1_7), offset 0x024**
- Register 11: AES Key 1_4 (AES_KEY1_4), offset 0x028**
- Register 12: AES Key 1_5 (AES_KEY1_5), offset 0x02C**
- Register 13: AES Key 1_2 (AES_KEY1_2), offset 0x030**
- Register 14: AES Key 1_3 (AES_KEY1_3), offset 0x034**
- Register 15: AES Key 1_0 (AES_KEY1_0), offset 0x038**
- Register 16: AES Key 1_1 (AES_KEY1_1), offset 0x03C**

This register contains the 32-bit key data for the AES module. This value can be expanded to 256-bits depending on the mode of operation. Table 13-6 on page 1008 describes the type of key that is held in register.

Note: Reads return zeros.

Table 13-6. AES Key Register Descriptions

Register Name	Address Offset	Description
AES_KEY2_6	0x000	Secure XTS second key / CBC-MAC third key
AES_KEY2_7	0x004	Secure XTS second key (MSW for 256-bit key) / CBC-MAC third key (MSW)
AES_KEY2_4	0x008	Secure XTS / CCM second key / CBC-MAC third key (LSW)
AES_KEY2_5	0x00C	Secure XTS second key (MSW for 192-bit key) / CBC-MAC third key
AES_KEY2_2	0x010	Secure XTS / CCM / CBC-MAC second key / Hash Key input
AES_KEY2_3	0x014	Secure XTS second key (MSW for 128-bit key) + CCM/CBC-MAC second key (MSW) / Hash Key input (MSW)
AES_KEY2_0	0x018	Secure XTS / CCM / CBC-MAC second key (LSW) / Hash Key input (LSW)
AES_KEY2_1	0x01C	Secure XTS / CCM / CBC-MAC second key / Hash Key input
AES_KEY1_6	0x020	Secure Key (LSW for 256-bit key)
AES_KEY1_7	0x024	Secure Key (MSW for 256-bit key)
AES_KEY1_4	0x028	Secure Key (LSW for 192-bit key)
AES_KEY1_5	0x02C	Secure Key (MSW for 192-bit key)

Table 13-6. AES Key Register Descriptions (continued)

Register Name	Address Offset	Description
AES_KEY1_2	0x030	Secure Key
AES_KEY1_3	0x034	Secure Key (MSW for 128-bit key)
AES_KEY1_0	0x038	Secure Key (LSW for 128-bit key)
AES_KEY1_1	0x03C	Secure Key

AES Key (AES_KEYn_n)

Base 0x4403.6000

Offset 0x000

Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0 KEY RW 0x00000000 Key Data

This register contains the 32-bit key data for the AES module.

Register 17: AES Initialization Vector Input 0 (AES_IV_IN_0), offset 0x040

Register 18: AES Initialization Vector Input 1 (AES_IV_IN_1), offset 0x044

Register 19: AES Initialization Vector Input 2 (AES_IV_IN_2), offset 0x048

Register 20: AES Initialization Vector Input 3 (AES_IV_IN_3), offset 0x04C

This register contains the initialization vector input.

AES Initialization Vector Input (AES_IV_IN_n)

Bit/Field	Name	Type	Reset	Description
31	CTXTRDY	RO	1	Context Data Registers Ready
				Value Description
				0 The context data registers are not ready to be overwritten.
				1 The context data registers can be overwritten and the host is permitted to write the next context.
30	SVCTXTRDY	RO	0	AES TAG/IV Block(s) Ready
				Note: This bit is only asserted if the SAVE_CONTEXT bit is set to 1. This bit is mutual exclusive with the CTXTRDY bit.
				Value Description
				0 AES authentication TAG and/or IV block(s) is/are not available.
				1 Indicates the AES authentication TAG and /or IV block(s) is/are available for the host to retrieve.
29	SAVE_CONTEXT	RW	0	TAG or Result IV Save
				If this bit is set, the CONTEXT_OUT interrupt bit is set in the AES_IRQSTATUS register if the operation is finished and related signals are enabled.
				Value Description
				0 No effect.
				1 Indicates an authentication TAG of result IV needs to be stored as a result context.

Bit/Field	Name	Type	Reset	Description														
28:25	reserved	R	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.														
24:22	CCM_M	RW	0	Counter with CBC-MAC (CCM) Defines M which indicates the length of the authentication field for CCM operations; the authentication field length equals two times the sum of CCM-M plus one. Note: The AES Engine always returns a 128-bit authentication field, of which the M least significant bytes are valid. All values are supported.														
21:19	CCM_L	RW	0	L Value Defines L, which indicates the width of the length field for CCM operations; the length field in bytes equals the value of CMM-L plus one. Supported values for L are: <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>width = 0</td></tr> <tr> <td>0x1</td><td>width = 2</td></tr> <tr> <td>0x2</td><td>reserved</td></tr> <tr> <td>0x3</td><td>width = 4</td></tr> <tr> <td>0x4 - 0x6</td><td>reserved</td></tr> <tr> <td>0x7</td><td>width = 8</td></tr> </tbody> </table>	Value	Description	0x0	width = 0	0x1	width = 2	0x2	reserved	0x3	width = 4	0x4 - 0x6	reserved	0x7	width = 8

Bit/Field	Name	Type	Reset	Description
8:7	CTR_WIDTH	RW	0	AES-CTR Mode Counter Width Value Description 0x0 Counter is 32 bits 0x1 Counter is 64 bits 0x2 Counter is 96 bits 0x3 Counter is 128 bits
6	CTR	RW	0	Counter Mode This bit must also be set for GCM and CCM mode, when encryption/decryption is required. Value Description 0 Counter mode is not enabled. 1 Counter mode is enabled.
5	MODE	RW	0	ECB/CBC Mode Value Description 0 ECB mode 1 CBC mode
4:3	KEY_SIZE	RW	0	Key Size Value Description 0x0 reserved 0x1 Key is 128 bits 0x2 Key is 192 bits 0x3 Key is 256 bits
2	DIRECTION	RW	0	Encryption/Decryption Selection If set to DIRECTION=1, an encrypt operation is performed. If set to 0, a decrypt operation is performed. Value Description 0 Decryption is selected. 1 Encryption is selected.
1	INPUT_READY	RO	0	Input Ready Status Value Description 0 Input buffer is not empty. 1 Indicates that the 16-byte input buffer is empty, and the host is permitted to write the next block of data.

Bit/Field	Name	Type	Reset	Description
0	OUTPUT_READY	RO	0	Output Ready Status
Value Description				
0				No AES output block is available.
1				An AES output block is available for the host to retrieve.

Register 22: AES Crypto Data Length 0 (AES_C_LENGTH_0), offset 0x054**Register 23: AES Crypto Data Length 1 (AES_C_LENGTH_1), offset 0x058**

AES Crypto Data Length n (AES_C_LENGTH_n) registers (LSW and MSW) store the cryptographic data length in bytes for all modes. The **AES_C_LENGTH_0** register stores the most significant word and the **AES_C_LENGTH_1** register stores the least significant word. Once processing with this context is started, this length decrements to zero. Data lengths up to $(2^{61} - 1)$ bytes are allowed. For GCM, any value up to 236 - 32 bytes can be used. This is because a 32-bit counter mode is used; the maximum number of 128-bit blocks is $2^{32} - 2$, resulting in a maximum number of bytes of $2^{36} - 32$. A write to this register triggers the engine to start using this context. This is valid for all modes except GCM and CCM. Note that for the combined modes, this length does not include the authentication only data; the authentication length is specified in the **AES_AUTH_LENGTH** register below. All modes must have a length greater than 0. For the combined modes, it is permissible to have one of the lengths equal to zero. For the basic encryption modes (ECB/CBC/CTR/ICM/CFB128) it is permissible to program zero to the length field; in that case the length is assumed infinite. All data must be byte (8-bit) aligned; bit aligned data streams are not supported by the AES Engine.

Note: For a Host read operation, these registers return all zeroes.

AES Crypto Data Length (AES_C_LENGTH_n)

Base 0x4403.6000
Offset 0x054
Type RW, reset 0x0000.0000

LENGTH

Bit/Field	Name	Type	Reset	Description
31:0	LENGTH	RW	0x00000000	Data Length This field stores the cryptographic data length in bytes for all modes.

Register 24: AES Authentication Data Length (AES_AUTH_LENGTH), offset 0x05C

The **AES Authentication Data Length (AES_AUTH_LENGTH)** register stores the authentication data length in bytes for combined modes only (GCM or CCM). Supported AUTH lengths for CCM are from 0 to $(2^{16} - 28)$ bytes. For GCM any value up to $(2^{32} - 1)$ bytes can be used. Once processing with this context is started, this length decrements to zero. A write to this register triggers the engine to start using this context for GCM and CCM. For XTS, this register is optionally used to load j. Loading of j is only required if $j \neq 0$. j is a 28-bit value and must be written to bits [31-4] of this register. j represents the sequential number of the 128-bit block inside the data unit. For the first block in a unit, this value is zero. It is not required to provide a j for each new data block within a unit. Note that it is possible to start with a j unequal to zero.

Note: For a Host read operation, these registers return all-zeroes..

AES Authentication Data Length (AES_AUTH_LENGTH)

Base 0x4403.6000
Offset 0x05C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	AUTH	RW	0x00000000	Authentication Data Length This field stores the authentication data length in bytes for combined modes (GCM or CCM).

Register 25: AES Data RW Plaintext/Ciphertext 0 (AES_DATA_IN_0), offset 0x060

Register 26: AES Data RW Plaintext/Ciphertext 1 (AES_DATA_IN_1), offset 0x064

Register 27: AES Data RW Plaintext/Ciphertext 2 (AES_DATA_IN_2), offset 0x068

Register 28: AES Data RW Plaintext/Ciphertext 3 (AES_DATA_IN_3), offset 0x06C

The **AES Data RW Plaintext/Ciphertext n (AES_DATA_IN_n)** registers are used to read and write plaintext/ciphertext. The **AES_DATA_IN_0** register contains the most significant word; the **AES_DATA_IN_3** register contains least significant word.

Note: The **AES_DATA_IN_0** register acts as a FIFO and shifts data into the other **AES_DATA_IN_n** registers.

AES Data RW Plaintext/Ciphertext (AES_DATA_IN_n)

Base 0x4403.6000
Offset 0x060
Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0 DATA RW 0x00000000 Secure Data RW Plaintext/Ciphertext
This field holds the plaintext/ciphertext data.

Register 29: AES Hash Tag Out 0 (AES_TAG_OUT_0), offset 0x070**Register 30: AES Hash Tag Out 1 (AES_TAG_OUT_1), offset 0x074****Register 31: AES Hash Tag Out 2 (AES_TAG_OUT_2), offset 0x078****Register 32: AES Hash Tag Out 3 (AES_TAG_OUT_3), offset 0x07C**

This register displays the Hash result. The **AES_TAG_OUT_0** register is the most significant word of the Hash and the **AES_TAG_OUT_3** register is the least significant word.

AES Hash Tag Out (AES_TAG_OUT_n)

Base 0x4403.6000

Offset 0x070

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	HASH	RW	0x00000000	Hash Result This field holds the hash result.

Register 33: AES IP Revision Identifier (AES_REVISION), offset 0x080

This register contains the IP revision number of the AES.

AES IP Revision Identifier (AES_REVISION)

Base 0x4403.6000

Offset 0x080

Type RO, reset 0x00000041

Bit/Field	Name	Type	Reset	Description

Bit/Field	Name	Type	Reset	Description
0	CONTEXT_IN	RO	0	Context In Interrupt Status
Value Description				
0				The context in interrupt is not active.
1				The context in interrupt is active and the interrupt output has been triggered.

Register 37: AES Interrupt Enable (AES_IRQENABLE), offset 0x090

This register contains an enable bit for each unique interrupt generated by the module. It matches the layout of **AES_IRQSTATUS** register. An interrupt is enabled when the bit in this register is set to 1. An interrupt that is enabled is propagated to the NVIC controller. All AES software interrupts need to be enabled explicitly by writing this register.

Note: If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, AES µDMA Mode should be used and the bits in the **AES_IRQENABLE** register should be cleared.

AES Interrupt Enable (AES_IRQENABLE)

Base 0x4403.6000
Offset 0x090
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	CONTEXT_OUT	RW	0	Context Out Interrupt Enable
	Value Description			
	0			Authentication tag (and IV) interrupt(s) is/are disabled.
	1			Authentication tag (and IV) interrupt(s) is/are enabled.
2	DATA_OUT	RW	0	Data Out Interrupt Enable
	Value Description			
	0			The data out interrupt is disabled.
	1			The data out interrupt is enabled.
1	DATA_IN	RW	0	Data In Interrupt Enable
	Value Description			
	0			The data in interrupt is disabled.
	1			The data in interrupt is enabled.

Bit/Field	Name	Type	Reset	Description
0	CONTEXT_IN	RW	0	Context In Interrupt Enable
Value Description				
		0		The context in interrupt is disabled.
		1		The context in interrupt is enabled.

Register 38: AES Dirty Bits (AES_DIRTYBITS), offset 0x094

This register can be used to identify if AES registers have been read or written to.

Bit/Field	Name	Type	Reset	Description
0	CIN	RW	0	Context In DMA Done Interrupt Mask If this bit is unmasked, an interrupt is generated when the µDMA completes a context write to the internal register.
Value Description				
0 The CIN interrupt is suppressed and not sent to the interrupt controller.				
1 The CIN interrupt is sent to the interrupt controller.				

Register 40: AES DMA Raw Interrupt Status (AES_DMARIS), offset 0x024

The **AES DMA Raw Interrupt Status (AES_DMARIS)** register contains the raw interrupt status. If any of these bits read 1, the processor is interrupted if the corresponding masked interrupt status bit is set to '1.'

AES DMA Raw Interrupt Status (AES_DMARIS)

Base 0x4403.0000
Offset 0x024
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	DOUT	RW	0	Data Out DMA Done Raw Interrupt Status
		Value	Description	
		0	No Interrupt.	
		1	The µDMA has written the last word of the process result and an interrupt has been triggered and is pending.	
2	DIN	RW	0	Data In DMA Done Raw Interrupt Status
		Value	Description	
		0	No Interrupt.	
		1	The µDMA has written the last word of input data to the internal FIFO of the engine and an interrupt has been triggered and is pending.	
1	COUT	RW	0	Context Out DMA Done Raw Interrupt Status
		Value	Description	
		0	No Interrupt.	
		1	The µDMA has completed the output context read from the internal register and an interrupt has been triggered and is pending.	

Bit/Field	Name	Type	Reset	Description
0	CIN	RW	0	Context In DMA Done Raw Interrupt Status
Value Description				
	0	No interrupt.		
	1	The µDMA has completed a context write to the internal register and an interrupt has been triggered and is pending.		

Register 41: AES DMA Masked Interrupt Status (AES_DMAMIS), offset 0x028

The **AES DMA Masked Interrupt Status (AES_DMAMIS)** register displays the raw interrupts that are unmasked in the **AES DMA Raw Interrupt Status (AES_DMARIS)** register.

AES DMA Masked Interrupt Status (AES_DMAMIS)

Base 0x4403.0000
Offset 0x028
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	DOUT	RO	0	Data Out DMA Done Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 A DOUT interrupt has occurred.
2	DIN	RO	0	Data In DMA Done Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 A DIN interrupt has occurred.
1	COUT	RO	0	Context Out DMA Done Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 A COUT interrupt has occurred.
0	CIN	RO	0	Context In DMA Done Raw Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 A CIN interrupt has occurred.

Register 42: AES DMA Interrupt Clear (AES_DMAIC), offset 0x02C

The **AES DMA Interrupt Clear (AES_DMAIC)** register is used to clear the **AES_DMARIS** and **AES_DMAMIS** registers by writing a 1 to each register bit.

Note: This register always reads as zero.

AES DMA Interrupt Clear (AES_DMAIC)

3	DOUT	W1C	0	Data Out DMA Done Interrupt Clear Writing a 1 to this bit clears the DOUT bit in the AES_DMARIS and AES_DMAMIS register.
2	DIN	W1C	0	Data In DMA Done Interrupt Clear Writing a 1 to this bit clears the DIN bit in the AES_DMARIS and AES_DMAMIS register.
1	COUT	W1C	0	Context Out DMA Done Masked Interrupt Status Writing a 1 to this bit clears the COUT bit in the AES_DMARIS and AES_DMAMIS register.
0	CIN	W1C	0	Context In DMA Done Raw Interrupt Status Writing a 1 to this bit clears the CIN bit in the AES_DMARIS and AES_DMAMIS register.

14 Data Encryption Standard Accelerator (DES)

The DES module provides hardware accelerated data encryption and decryption functions. The module runs either the single DES or the triple DES (3DES) algorithm in compliance with the [FIPS 46-3 standard](#) and supports electronic codebook (ECB), cipher block chaining (CBC), and cipher feedback (CFB) modes of operation. It does not support the output feedback (OFB) mode of operation in hardware.

The purpose of the DES algorithm is to encrypt (encipher) or decrypt (decipher) binary coded information. Encrypting data converts it to an unintelligible form called cipher text. Decrypting cipher text converts the data back to its original form called plaintext. DES is a symmetrical algorithm in that the encryption and decryption keys are identical. Each triple DES encrypt/decrypt operation is a compound of DES encrypt and decrypt operations.

The DES accelerator includes the following main features:

- DES/3DES encryption and decryption.
- Feedback modes: ECB, CBC, CFB
- Host interrupt or μDMA driven modes of operation. μDMA support for data and context in/result out
- Fully synchronous design
- Internal wide-bus interface

14.1 DES Functional Description

The DES module is an efficient implementation of a DES block cipher. Block ciphers, as opposed to stream ciphers, operate on blocks of plain text and cipher text. The DES block size is 8-byte. The DES key consists of 64 binary digits, but only 56 bits are actually used directly by the algorithm. The other 8 bits are used for error detection.

The 64-bit block of input data to be enciphered is initially permuted, then passed through 16 iterations of a calculation that uses a cipher function and finally permuted to the inverse of the initial permutation. At each of the 16 iterations, a 48-bit key computed from the 64-bit input key is applied to one of the 32-bit sub-blocks of the 64-bit input block using the cipher function. The 48-bit key value changes for each iteration. The result of the cipher function is a 32-bit sub-block, which is concatenated with the second 32-bit input sub-block. The resulting 64-bit output block of each iteration feeds back as the input of the next iteration. To decipher, it is only necessary to apply the same algorithm to the enciphered message block, taking care that each iteration of the computation will use the same 48-bit key which was used during enciphering.

The triple DES is the DES used three times in a row (also known as DES-EDE). It uses three keys key1, key2, and key3, so that key length is 168 bits effective: a 64-bit block plaintext is encrypted with key1, decrypted with key2, and encrypted with key3, and a 64-bit ciphertext is decrypted with key1, encrypted with key2, and decrypted with key3.

There are three keying options defined in ANSI X9.52 for DES-EDE:

- The three keys key1, key2, and key3 are independent.
- key1 and key2 are independent, but key1 = key3
- key1 = key2 = key3

The first option provides highest level of security; the last option is compatible with single DES. See Table 14-1 on page 1037 for key use.

Table 14-1. Key Repartition

Mode	Key1_L	Key1_H	Key2_L	Key2_H	Key3_L	Key3_H
64-bit (DES)	√	√	X	X	X	X
192-bit (3DES)	√	√	√	√	√	√

ECB, CBC, and CFB modes can be used with DES and 3DES modes.

14.2 DES Block Diagram

The module architecture consists of primary blocks, as shown in Figure 14-1 on page 1037. The DES module includes a register interface, and a μDMA and interrupt interface.

Depending of the availability of context and data, the DES engine is automatically triggered to process the data. The DES engine is directly connected to the context and data registers such that it can immediately start processing when all data is available.

Packets (blocks of 64 bits) must be parsed into blocks and sequentially fed into the DES, which can buffer the block currently being processed as well as an additional block that may be queued in advance.

Figure 14-1. DES Block Diagram

14.2.1 μDMA Control

The μDMA and interrupt request logic is controlled by the DES Engine. The DES Engine can have multiple μDMA request signals active in parallel.

There are three DMA channels available:

- DMA context in - Request a new context (DES0 Cin)
- DMA data in - Request input data (DES0 Din)
- DMA data out - Request output data read (DES0 Dout)

14.2.2 Interrupt Control

There is one interrupt for the DES that is sent to the interrupt controller. This interrupt is an OR of the enabled interrupt bits in the **DES Interrupt Status (DES_IRQSTATUS)** register. These bits are enabled through the **DES Interrupt Enable (DES_IRQENABLE)** register. The following events can generate an interrupt bit to be set in the **DES_IRQSTATUS** register. These are:

- New context input required
- Data input required
- Data output ready

14.2.3 Register Interface

The Register Interface block performs all address decoding and control; however, not all registers are available in this block. The context and data input registers are in the DES engine.

14.2.4 DES Engine

The DES buffered engine consists of the following major functional blocks:

- Cipher core: the DES algorithm
- Mode control FSM: manages the data flow to and from the DES buffered engine and starts each encrypt/decrypt operation
- DES feedback mode block: the logic that implements the various feedback modes supported by the DES buffered engine

14.2.4.1 Mode Control FSM

The Mode control FSM manages the data flow to and from the DES engine. This block also sends a start pulse to the encrypt/decrypt core and triggers the core to use the new mode keys when a new context is needed. This module also controls the 3DES operation, such that the DES core module is triggered three times (with different keys) before the result data becomes available.

14.2.4.2 DES Feedback Mode Block

The DES feedback mode block buffers the input and output blocks and contains all logic to implement the 3DES and various feedback modes. See the FIPS-81 document for details on the ECB, CBC, and CFB modes of operation.

By itself, the DES cipher core outputs data compliant for ECB encryption. However, most applications use DES with feedback. Feedback provides additional security by randomizing repeated patterns in the plain text, which could otherwise be exploited to attack the cipher text. The DES buffered engine supports ECB, CBC, and CFB modes of operations for the DES and 3DES algorithm.

3DES mode performs the DES algorithm three times on a single block and uses a different key for each invocation of the DES algorithm, greatly increasing security of the cipher text but at the cost

of a 3x reduction in throughput. The DES buffered engine implements a 3DES logic wrapper around the 2-round DES core, enabling seamless 3DES encryption.

14.2.4.3 DES Cipher Core

The DES cipher core implements the DES algorithm as specified in the FIPS 46-3. The core operates on the input block and performs the required substitution, shift, and mix operations. The core also applies the correct key-scheduling.

Inherently, considerable parallelism is possible with the DES algorithm. This is exploited in two ways. For high performance, the 64 bits composing the data block are processed concurrently (4-round implementation). For low gate-count, resources are shared on both the main data and key paths (1-round implementation).

A fundamental component of the DES algorithm is the substitution box (S-Box). The S-Box provides a unique 4-bit output for each 6-bit input. The S-Box design is a primary factor for both performance and gate count. The DES Cipher Core has a standard lookup table S-Box that allows room for the synthesizer to optimize on timing or gate count.

14.3 Software Reset

Table 14-2 on page 1039 lists the resets used in the DES module.

Table 14-2. DES Reset Description

Type	Name	Source	Description
Hardware	DES_RST	PRCM	Global reset
Software	DES_SYSCONFIG [1] SOFTRESET	Internal	Starts the soft reset sequence. When the DES_SYSSTATUS/DES_P_SYSSTATUS[0] RESETDONE bit goes to 1, the soft reset sequence is finished.

14.4 DES Supported Modes of Operation

14.4.1 ECB Feedback Mode

Figure 14-2 on page 1040 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output of the cryptographic core is passed directly to the output buffer. For decryption the DES core operates in reverse, this means the decrypt key sequence is used for the data processing, where encryption uses the encrypt key sequence.

Figure 14-2. DES - ECB Feedback Mode**14.4.1.1 CBC Feedback Mode**

Figure 14-3 on page 1040 shows the CBC feedback mode of operation, where the input data is XORed with the initialization vector (IV) before it is passed to the basic crypto core. The output of the crypto core is passed directly to the output buffer. For decryption the operation is reversed, resulting in an XOR at the output of the crypto core.

Figure 14-3. DES3DES - CBC Feedback Mode**14.4.1.2 CFB Feedback Mode**

Figure 14-4 on page 1041 shows the CFB mode of operation for encryption and decryption. The input for the crypto core is the IV; the result is XORed with the data. The result is fed back via the IV register, as the next input for the crypto core. The decrypt operation is reversed, but the crypto core is still performing an encryption.

Figure 14-4. DES3DES-CFB Feedback Mode

14.5 DES Module Programming Guide -Low Level Programming Models

14.5.1 Surrounding Modules Global Initialization

14.5.1.1 Main Sequence - DES Global Initialization

This procedure initializes the DES after a POR.

Table 14-3. DES Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	DES_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	DES_SYSSTATUS[0] RESETDONE	= 0x1
Select force idle mode	DES_SYSCONFIG[3:2] SIDLE	0x0
Select the algorithm type (DES or 3DES)	See the programming models	
Select the operating mode (ECB, CBC or CFB).	DES_CTRL[5:4] MODE	-
IF: ECB operating mode not selected.	DES_CTRL[5:4] MODE	≠ 0x0
Load the initialization vector LSW.	DES_IV_L[31:0] IV_L	-
Load the initialization vector MSW.	DES_IV_H[31:0] IV_H	-
Define the cryptographic data length.	DES_LENGTH[31:0] LENGTH	-
ENDIF		
Select encryption or decryption.	DES_CTRL[2] DIRECTION	-

14.5.1.2 Subsequence - Configure the DES Algorithm Type

This subsequence details the DES algorithm type settings.

Table 14-4. DES Algorithm Type Configuration

Step	Register/Bit Field/Programming Model	Value
Load key 1 LSW.	DES_KEY1_L[31:0] KEY1_L	-
Load key 1 MSW.	DES_KEY1_H[31:0] KEY1_H	-
Select DES algorithm.	DES_CTRL[3] TDES	0x0

14.5.1.3 Subsequence - Configure the 3DES Algorithm Type

This subsequence details the 3DES algorithm type settings.

Table 14-5. 3DES Algorithm Type Configuration

Step	Register/Bit Field/Programming Model	Value
Load key 1 LSW.	DES_KEY1_L[31:0] KEY1_L	-
Load key 1 MSW.	DES_KEY1_H[31:0] KEY1_H	-
Load key 2 LSW.	DES_KEY2_L[31:0] KEY2_L	-
Load key 2 MSW.	DES_KEY2_H[31:0] KEY2_H	-
Load key 3 LSW.	DES_KEY3_L[31:0] KEY3_L	-
Load key 3 MSW.	DES_KEY3_H[31:0] KEY3_H	-
Select 3DES algorithm.	DES_CTRL[3] TDES	0x1

14.5.2 Operational Modes Configuration

14.5.2.1 Main Sequence - DES Polling Mode

Figure 14-5 on page 1043 shows DES polling mode. The registers used in DES polling mode are: DES_DATA_L, DES_DATA_H, and DES_CTRL.

Figure 14-5. DES Polling Mode

14.5.2.2 DES Interrupt Mode

Table 14-6 on page 1043 lists the DES interrupt mode steps.

Table 14-6. DES Interrupt Mode

Step	Register/Bit Field/Programming Model	Value
Enable DES module interrupts.	DES_IRQENABLE[2:0]	0x7
Load the input buffer data LSW register.	DES_DATA_L[31:0] DATA_L	-
Load the input buffer data HSW register.	DES_DATA_H[31:0] DATA_H	-

14.5.2.3 DES Interrupt DMA Mode

Table 14-7 on page 1043 lists the DES DMA mode steps.

Table 14-7. DES DMA Mode

Step	Register/Bit Field/Programming Model	Value
Enable DES module DMA requests.	DES_SYSConfig[7:5]	0x7
Load the input buffer data LSW register.	DES_DATA_L[31:0] DATA_L	-

Table 14-7. DES DMA Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Load the input buffer data HSW register.	DES_DATA_H[31:0] DATA_H	-

14.5.3 DES Events Servicing

14.5.3.1 Interrupt Servicing

This section describes the event servicing of the module. Figure 14-6 on page 1044 shows the DES interrupt service. The registers used during event servicing are: DES_IRQSTATUS, DES_DATA_L, and DES_DATA_H.

Figure 14-6. DES Interrupt Service

14.5.3.2 Context Input Event Servicing

This section describes the context input event servicing of the module, as shown in Figure 14-7 on page 1045. The registers used during event servicing are: DES_CTRL, DES_SYSCONFIG, DES_KEY1_L, DES_KEY1_H, DES_KEY2_L, DES_KEY2_H, DES_KEY3_L, DES_KEY3_H, DES_IV_L, DES_IV_H, and DES_LENGTH.

Figure 14-7. DES Context Input Event Service

14.6 Register Map

Table 14-8 on page 1045 lists the DES registers. The DES Module comprises registers that exist at an offset relative to the DES Module base address and a small set of DES µDMA registers that exist at an offset relative to an Encryption Control Module base address. The DES Module register offsets are relative to the base address 0x4403.8000 . The Encryption Control register offsets are relative to the base address 0x4403.0000.

Note: The DES registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed and can corrupt register contents.

Table 14-8. DES Register Map

Offset	Name	Type	Reset	Description	See page
DES Module Registers (DES Module Offset)					
0x000	DES_KEY3_L	RW	0x0000.0000	DES Key 3 LSW for 192-Bit Key	1047

14.7 DES Register Description

This section lists and describes the DES registers, in numerical order by address offset.

- Register 1: DES Key 3 LSW for 192-Bit Key (DES_KEY3_L), offset 0x000**
Register 2: DES Key 3 MSW for 192-Bit Key (DES_KEY3_H), offset 0x004
Register 3: DES Key 2 LSW for 128-Bit Key (DES_KEY2_L), offset 0x008
Register 4: DES Key 2 MSW for 128-Bit Key (DES_KEY2_H), offset 0x00C
Register 5: DES Key 1 LSW for 64-Bit Key (DES_KEY1_L), offset 0x010
Register 6: DES Key 1 MSW for 64-Bit Key (DES_KEY1_H), offset 0x014

The function of each of these registers is described in more detail in Table 14-9 on page 1047.

Note: A read of this register returns all zeros.

Table 14-9. DES Key Register Mapping

Register Name	Address Offset	Description
DES_KEY3_L	0x00000000	KEY3 (LSW) for 192-bit key
DES_KEY3_H	0x00000004	KEY3 (MSW) for 192-bit key
DES_KEY2_L	0x00000008	KEY2 (LSW) for 192-bit key
DES_KEY2_H	0x0000000C	KEY2 (MSW) for 192-bit key
DES_KEY1_L	0x00000010	KEY1 (LSW) for 64-bit key/192-bit key
DES_KEY1_H	0x00000014	KEY1 (MSW) for 64-bit key/192-bit key

DES Key for 192-Bit Key (DES_KEYn_n)

Base 0x4403.8000

Offset 0x000

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	KEY	RW	0x00000000	Key Data

Register 7: DES Initialization Vector (DES_IV_L), offset 0x018

Least significant word of the initialization vector.

DES Initialization Vector (DES_IV_L)

Base 0x4403.8000

Offset 0x018

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	IV_L	RW	0x00000000	Initialization vector for CBC, CFB modes (LSW)

Register 8: DES Initialization Vector (DES_IV_H), offset 0x01C

Most significant word of the initialization vector.

DES Initialization Vector (DES_IV_H)

Base 0x4403.8000
Offset 0x01C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	IV_H	RW	0x00000000	Initialization vector for CBC, CFB modes (MSW)

Register 9: DES Control (DES_CTRL), offset 0x020

DES Control (DES_CTRL)

Base 0x4403.8000
Offset 0x020
Type RW, reset 0x8000.0000

Bit/Field	Name	Type	Reset	Description
31	CONTEXT	R	1	If 1, this read-only status bit indicates that the context data registers can be overwritten and the host is permitted to write the next context.
30:6	reserved	R	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:4	MODE	RW	0	Select CBC, ECB or CFB mode0x0: ECB mode0x1: CBC mode0x2: CFB mode0x3: reserved
3	TDES	RW	0	Select DES or triple DES encryption/decryption.0x0: DES mode0x1:TDESmode
2	DIRECTION	RW	0	Select encryption/decryption 0x0: decryption is selected0x1: Encryption is selected
1	INPUT_READY	R	0	When 1, ready to encrypt/decrypt data
0	OUTPUT_READY	R	0	When 1, Data decrypted/encrypted ready

Register 10: DES Cryptographic Data Length (DES_LENGTH), offset 0x024

Indicates the cryptographic data length in bytes for all modes. Once processing is started with this context, this length decrements to zero. Data lengths up to (232 - 1) bytes are allowed. A write to this register triggers the engine to start using this context.

Note: A read of this register returns all zeros.

DES Cryptographic Data Length (DES_LENGTH)

Base 0x4403.8000
Offset 0x024
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	LENGTH	RW	0x00000000	Cryptographic data length in bytes for all modes

Register 11: DES LSW Data RW (DES_DATA_L), offset 0x028

Data register (LSW) to read/write encrypted/decrypted data.

DES LSW Data RW (DES_DATA_L)

Base 0x4403.8000
Offset 0x028
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	DATA_L	RW	0x00000000	Data for encryption/decryption, LSW

Register 12: DES MSW Data RW (DES_DATA_H), offset 0x02C

Data register (MSW) to read/write encrypted/decrypted data.

DES MSW Data RW (DES_DATA_H)

Base 0x4403.8000
Offset 0x02C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	DATA_H	RW	0x00000000	Data for encryption/decryption, MSW

Register 13: DES Revision Number (DES_REVISION), offset 0x030**Revision Number****DES Revision Number (DES_REVISION)**

Base 0x4403.8000

Offset 0x030

Type RO, reset 0x0000.0021

Bit/Field	Name	Type	Reset	Description
31:0	REVISION	RO	0x0000.0021	Revision number

Register 14: DES System Configuration (DES_SYSCONFIG), offset 0x034

System Configuration of DES module

Note: After one operation has completed, the **DES_SYSCONFIG** register must be cleared and re-configured for the next operation to ensure proper DMA and data operation functionality.

DES System Configuration (DES_SYSCONFIG)

Base 0x4403.8000

Offset 0x034

Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	DMA_REQ_CONTEXT_IN_EN	RW	0	DMA Request Context In Enable
	Value	Description		
	0	DMA disabled		
	1	DMA enabled		
6	DMA_REQ_DATA_OUT_EN	RW	0	DMA Request Data Out Enable
	Value	Description

Value	Description									
0	No operation									
1	Start soft reset sequence									
0	reserved	RO	1	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						

Register 15: DES System Status (DES_SYSSTATUS), offset 0x038

System Status Register

DES System Status (DES_SYSSTATUS)

Base 0x4403.8000

Offset 0x038

Type RO, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:1 reserved RO 0 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

0 RESETDONE RO 1 Reset Done

Value	Description
0	Reset is not complete
1	Reset done

Register 16: DES Interrupt Status (DES_IRQSTATUS), offset 0x03C

This register indicates the interrupt status. If one of the interrupt bits is set the interrupt output will be asserted.

DES Interrupt Status (DES_IRQSTATUS)

Base 0x4403.8000
Offset 0x03C
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	DATA_OUT	RO	0	This bit indicates data output interrupt is active and triggers the interrupt output.
1	DATA_IN	RO	0	This bit indicates data input interrupt is active and triggers the interrupt output.
0	CONTEX_IN	RO	0	This bit indicates context interrupt is active and triggers the interrupt output.

Register 17: DES Interrupt Enable (DES_IRQENABLE), offset 0x040

This register contains an enable bit for each unique interrupt generated by the module. It matches the layout of **DES_IRQSTATUS** register. An interrupt is enabled when the bit in this register is set to 1.

DES Interrupt Enable (DES_IRQENABLE)

Base 0x4403.8000
Offset 0x040
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	M_DATA_OUT	RW	0	If this bit is set to 1 the data output interrupt is enabled.
1	M_DATA_IN	RW	0	If this bit is set to 1 the data input interrupt is enabled.
0	M_CONTEX_IN	RW	0	If this bit is set to 1 the context interrupt is enabled.

Register 18: DES Dirty Bits (DES_DIRTYBITS), offset 0x044

DES Dirty Bits (DES_DIRTYBITS)

Base 0x4403.8000
Offset 0x044
Type RW1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	R	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	S_DIRTY	RW1C	0	This bit is set to 1 by the module if any of the DES_* registers is written. Except DES_DIRTYBITS and DES_LOCKDOWN.
0	S_ACCESS	RW1C	0	This bit is set to 1 by the module if any of the DES_* registers is read. Except DES_DIRTYBITS and DES_LOCKDOWN.

14.8 DES µDMA Interrupt Register Descriptions (CCM Offset)

This section lists and describes the DES µDMA registers, in numerical order by address offset. Registers in this section are relative to the base address of 0x4403.0000.

Register 19: DES DMA Interrupt Mask (DES_DMAIM), offset 0x030

The **DES DMA Interrupt Mask** register control interrupt behavior and are used to program which interrupts are suppressed.

DES DMA Interrupt Mask (DES_DMAIM)

Base 0x4403.0000
Offset 0x030
Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:3 reserved RO 0x0000.000 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

2 DOUT RW 0 Data Out DMA Done Interrupt Mask
If this bit is unmasked, an interrupt is generated when the µDMA writes the last word of the process result.

Value	Description
0	The DOUT interrupt is suppressed and not sent to the interrupt controller.
1	The DOUT interrupt is sent to the interrupt controller.

1 DIN RW 0 Data In DMA Done Interrupt Mask
If this bit is unmasked, an interrupt is generated when the µDMA writes the last word of input data to the internal FIFO of the engine.

Value	Description
0	The DIN interrupt is suppressed and not sent to the interrupt controller.
1	The DIN interrupt is sent to the interrupt controller.

0 CIN RW 0 Context In DMA Done Interrupt Mask
If this bit is unmasked, an interrupt is generated when the µDMA completes a context write to the internal register.

Value	Description
0	The CIN interrupt is suppressed and not sent to the interrupt controller.
1	The CIN interrupt is sent to the interrupt controller.

Register 20: DES DMA Raw Interrupt Status (DES_DMARIS), offset 0x034

The **DES DMA Raw Interrupt Status** register contains the raw interrupt status. If any of these bits read 1, the processor is interrupted if the corresponding masked interrupt status bit is set to 1.

DES DMA Raw Interrupt Status (DES_DMARIS)

Base 0x4403.0000
Offset 0x034
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	DOUT	RW	0	Data Out DMA Done Raw Interrupt Status Value Description 0 No Interrupt. 1 The µDMA has written the last word of the process result and an interrupt has been triggered and is pending.
1	DIN	RW	0	Data In DMA Done Raw Interrupt Status Value Description 0 No Interrupt. 1 The µDMA has written the last word of input data to the internal FIFO of the engine and an interrupt has been triggered and is pending.
0	CIN	RW	0	Context In DMA Done Raw Interrupt Status Value Description 0 No interrupt. 1 The µDMA has completed a context write to the internal register and an interrupt has been triggered and is pending.

Register 21: DES DMA Masked Interrupt Status (DES_DMAMIS), offset 0x038

The **DES DMA Masked Interrupt Status** register displays the raw interrupts that are unmasked in the **DES DMA Raw Interrupt Status (DES_DMARIS)** register.

DES DMA Masked Interrupt Status (DES_DMAMIS)

Base 0x4403.0000
Offset 0x038
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	DOUT	RO	0	Data Out DMA Done Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 A DOUT interrupt has occurred.
1	DIN	RO	0	Data In DMA Done Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 A DIN interrupt has occurred.
0	CIN	RO	0	Context In DMA Done Raw Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 A CIN interrupt has occurred.

Register 22: DES DMA Interrupt Clear (DES_DMAIC), offset 0x03C

The **DES DMA Interrupt Clear** register is used to clear the **DES_DMARIS** and **DES_DMAMIS** registers by writing a 1 to the corresponding register bit.

Note: This register always reads as zero.
