reserved																
Type	RO	W1C	W1C	W1C												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	DOUT	W1C	0	Data Out DMA Done Interrupt Clear Writing a 1 to this bit clears the DOUT bit in the DES_DMARIS and DES_DMAMIS register.
1	DIN	W1C	0	Data In DMA Done Interrupt Clear Writing a 1 to this bit clears the DIN bit in the DES_DMARIS and DES_DMAMIS register.
0	CIN	W1C	0	Context In DMA Done Raw Interrupt Status Writing a 1 to this bit clears the CIN bit in the DES_DMARIS and DES_DMAMIS register.

15 SHA/MD5 Accelerator

The SHA/MD5 module provides hardware-accelerated hash functions and can run:

- MD5 message digest algorithm developed by Ron Rivest in 1991
- SHA-1 algorithm compliant with the [FIPS 180-3 standard](#)
- SHA-2 (SHA-224 and SHA-256) algorithm compliant with the FIPS 180-3 standard
- Hash message authentication code (HMAC) operation

The algorithms produce a condensed representation of a message or a data file, called digest or signature, which can then be used to verify the message integrity.

- Hashing of 0 to 2^{33} - 2 bytes of data (of which 2^{32} - 1 bytes are in one pass) using the MD5, SHA-1, SHA-224, or SHA-256 hash algorithm (byte granularity only, no support for bit granularity)
- Automatic HMAC key preprocessing for HMAC keys up to 64 bytes
- Host-assisted HMAC key preprocessing for HMAC keys larger than 64 bytes
- HMAC from precomputes (inner/outer digest) for improved performance on small blocks
- Supports μDMA operation for data and context in/result out transfers
- Supports interrupt to read the digest (signature)

15.1 SHA/MD5 Functional Description

15.1.1 SHA/MD5 Block Diagram

Figure 15-1 on page 1066 shows the module architecture, which consists of four primary blocks: the Hash/HMAC engine, the configuration registers and the interface to μDMA and the interrupt handler.

Figure 15-1. SHA/MD5 Module Block Diagram

15.1.1.1 Configuration Registers

The configuration registers contain the following global control and status registers for the SHA/MD5 Module:

- System control register that controls the mode of operation (**SHA_SYSCONFIG** register)
- μDMA interrupt control registers (**SHA_DMAIM**, **SHA_DMARIS**, **SHA_DMAMIS**, and **SHA_DMAIC** registers, which reside in the Encryption Control Base address space)
- Interrupt status register (**SHA_IRQSTATUS** register)
- Enable register (**SHA_IRQENABLE** register)

15.1.1.2 Hash/HMAC Engine

The Hash/HMAC engine performs the SHA-1, SHA-2, or MD5 hash computation. When loaded with a data block, and optionally an intermediate digest, it independently performs the hash computation (64 or 80 rounds, depending on the algorithm) on that data block.

It can also start from the specified initial digest values instead of a loaded intermediate. Furthermore, it can perform the IPAD and OPAD XORs for MAC operations. The hash core does not perform any hash padding; this is performed in the Host Interface Block, where the data input registers are located. A loaded data block must always be a full 64 bytes (512 bits) long.

15.1.1.3 Hash Core Control

When the hash core is idle or done, a new hash operation can be started. Any additional information needed by the hash core (mode of operation, data to process, input digest if not starting from algorithm constants or continuing) must be provided by programming the SHA registers before the core can accept the operation.

15.1.1.4 Host Interface Bank

The Host Interface Bank can access the hash core for hashing individual 64-byte hash blocks. The Host Interface Bank contains registers such as the data FIFO (**SHA Data n Input (SHA_DATA_n_IN)** registers), the **SHA Inner Digest x (SHA_IDIGEST_X)** registers, and several control and status registers.

The Host Interface Block contains all relevant control logic for performing hash and HMAC computations on large (that is, larger than one hash block) blocks of data, including hash padding, final hash, and outer hash. It provides the necessary flow control to the SHA µDMA and interrupt interface.

15.1.2 Power Management

To save power, the application can disable the clock to the SHA/MD5 module when not in use. The SHA/MD5 is clock gated by setting the **SHACFG** bit in the **Cryptographic Modules Clock Gating Request (CCMCGREQ)** register, CCM offset 0x204. The SHA in addition to the AES, DES, and Enhanced CRC can also be clock gated as a group by setting the **D0** bit in the **CRC and Cryptographic Modules Deep-Sleep Mode Clock Gating Control (DCGCCCM)** register, System Control Module offset 0x874.

15.1.3 Reset Management

To perform a software reset of the SHA module, write a 1 to the **SOFTRESET** bit in the **SHA System Configuration (SHA_SYSCONFIG)** register. The **RESETDONE** bit in the **SHA System Status (SHA_SYSSTATUS)** register indicates that the software reset is complete when its value is 1. When the software reset completes, the **SOFTRESET** bit in the **SHA_SYSCONFIG** register is automatically reset. Software must ensure that the software reset completes before doing any operations.

The behavior of the software reset is the same as the hardware reset, except that the software reset bit resets this module without affecting the reset core domain of the entire device.

15.1.4 µDMA and Interrupt Requests

The SHA/MD5 module can operate in µDMA mode where the module can assert a µDMA request for context in, context out, or data input. The µDMA signals that can be generated are:

- Context In µDMA request (SHA/MD5 0 Cin): Request for Key, Digest, Mode and LENGTH information
- Context Out µDMA request (SHA/MD5 0 Cout): Request for read from HMAC
- Data In µDMA request (SHA/MD5 0 Din): Request input data in multiples of 16 bytes

The SHA/MD5 Module be programmed to assert an interrupt when the µDMA has completed its last transfer by programming the **SHA DMA Interrupt Mask (SHA_DMAIM)**, at the CRC and Cryptographic Modules (CCM) offset 0x010. The **SHA DMA Raw Interrupt Status (SHA_DMARIS)** register, at CCM offset 0x014, indicates when the µDMA has completed and can be cleared by the **SHA DMA Interrupt Clear (SHA_DMAIC)** register at CCM offset 0x01C.

Note: The SHA module can only be accessed through privileged mode. If the µDMA is used for SHA transfers, then the µDMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

If context and data transfers are to be handled through software in Interrupt Mode, then the **SHA Interrupt Enable (SHA_IRQENABLE)**, offset 0x11C, can be used to enable interrupt triggering

when context out, context in, data in or data out is ready. The **SHA Interrupt Status (SHA_IRQSTATUS)**, offset 0x118, indicates when an interrupt is triggered.

Note: If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, SHA µDMA Mode should be used and the bits in the **SHA_IRQENABLE** register should be cleared.

Table 15-1. Interrupts and Events

Event	Description
SHA_IRQSTATUS[3]: CONTEXT_OUT	Context output interrupt
SHA_IRQSTATUS[1]: DATA_IN	Data input interrupt
SHA_IRQSTATUS[0]: CONTEXT_IN	Context input interrupt

15.1.5 Operation Description

The SHA/MD5 Module can run the SHA-1, SHA-224, SHA-256, and MD5 algorithms, depending on the value of the ALGO bit field in the **SHA Mode (SHA_MODE)** register, offset 0x044, as listed in Table 15-2 on page 1068.

Table 15-2. SHA/MD5 Module Algorithm Selection

ALGO Field Value in SHA_MODE Register	Description
0x0	MD5 algorithm selected
0x1	SHA-1 algorithm selected
0x2	SHA-224 algorithm selected
0x3	SHA-256 algorithm selected

15.1.5.1 SHA Mode

Starting a New Hash

To start a new hash, follow these steps:

1. Set the ALGO bitfield in the **SHA_MODE** register, at offset 0x044, to 0x1, 0x2, or 0x3 to select SHA-1, SHA-224, or SHA-256, respectively.
2. Set the ALGO_CONSTANT bit in the **SHA_MODE** register to 1 to initialize all **SHA Inner/Outer Digest n** registers from **SHA_ODIGEST_A/SHA_IDIGEST_A** to **SHA_ODIGEST_H/SHA_IDIGEST_H** with their default values specified by the algorithm, and set the **SHA_DIGESTCOUNT** register to 0.
3. Set the CLOSE_HASH bit of the **SHA Mode (SHA_MODE)** register to let the SHA engine do the padding. If the Hash is computed in one shot, the length of the message can be any value up to 128 MB. To process an intermediate Hash digest, the CLOSE_HASH bit is set to 0, in which case the packets hashed must be 64 bytes; the last packet must be hashed with the CLOSE_HASH bit set to 1.
4. Specify the LENGTH field in the **SHA Length (SHA_LENGTH)** register of the hash data to process in bytes.

After the configuration is complete, the INPUT_READY status bit equals 1 in the **SHA Interrupt Status (SHA_IRQSTATUS)** register (regardless of whether or not the M_INPUT_READY bit in the **SHA_IRQENABLE** register is set. When this bit is set, it indicates the SHA engine can receive the

data to process. Data must be written to the 16×32 -bit **SHA_DATA_n_IN** registers that provide storage for one 64-byte block of data. Unless the **CLOSE_HASH** bit is set, all of the **SHA_DATA_n_IN** input buffers must be filled. Data can be written by single write accesses to the 16 registers from a processor or by a DMA transfer.

For μDMA transfers, the **DMA_EN** bit must be set in the **SHA_SYSConfig** register and the appropriate mask bits must be set in the **SHA_DMAIM** register before starting the new hash. Note that if the μDMA is used for transfers, the **SHA_IRQENABLE** register should be clear so all interrupts are generated through the μDMA interrupt registers.

The μDMA must be configured to transfer 16 data words of 32 bits each time it is triggered by a μDMA request from the SHA/MD5 Module. The 16 data words written are sent to the 16 **SHA_DATA_n_IN** registers.

The module detects that a 64-byte block is available, and then moves the data to a working register space for processing and asserts the **INPUT_READY** bit in the **SHA_IRQSTATUS** register to 1. If the **DMA_EN** bit in the **SHA_SYSConfig** register has been set to 1, a new μDMA request triggers a new block transfer; otherwise, the processor polls the **INPUT_READY** bit and writes the 16 data words of 32 bits when it equals 1.

This operation is repeated until the length of the message to hash is reached. The **OUTPUT_READY** bit in the **SHA_IRQSTATUS** register then indicates that the hash operation is complete. If the **IT_EN** bit in the **SHA_SYSConfig** register is set, an interrupt (active low) is also generated to indicate the hash completion.

The processor can then read the eight digest registers A through H that contain the hash and/or HMAC result. If the hash is an intermediate result of a larger hash, the digest count register must also be read and saved.

Note: The number of digest registers used depends on the algorithm selected for the SHA/MD5 Module (MD5, SHA-1, SHA-224, or SHA-256), as shown in Table 15-3 on page 1069 and Table 15-4 on page 1070

Table 15-3. Outer Digest Registers

Register	Address	MD5 (Read/Write)	SHA-1 (Read/Write)	SHA-2 (Read/Write)	HMAC Key Processing (write)
SHA_ODIGEST_A	0x000	Outer digest [127:96]	Outer digest [159:128]	Outer digest [255:224]	HMAC Key [31:0]
SHA_ODIGEST_B	0x004	Outer digest [95:64]	Outer digest [127:96]	Outer digest [223:192]	HMAC key [63:32]
SHA_ODIGEST_C	0x008	Outer digest [63:32]	Outer digest [95:64]	Outer digest [191:160]	HMAC key [95:64]
SHA_ODIGEST_D	0x00C	Outer digest [31:0]	Outer digest [63:32]	Outer digest [159:128]	HMAC key [127:96]
SHA_ODIGEST_E	0x010		Outer digest [31:0]	Outer digest [127:96]	HMAC key [159:128]
SHA_ODIGEST_F	0x014			Outer digest [95:64]	HMAC key [191:160]
SHA_ODIGEST_G	0x018			Outer digest [63:32]	HMAC key [223:192]
SHA_ODIGEST_H	0x01C			Outer digest [31:0]	HMAC key [255:224]

Table 15-4. Inner Digest Registers

Register	Address	MD5 (Read/Write)	SHA-1 (Read/Write)	SHA-2 (Read/Write)	SHA-256 (Read/Write)	HMAC Key Processing (write)
SHA_IDIGEST_A	0x020	Inner digest [127:96]	Inner digest [159:128]	Inner digest [223:192]	Inner digest [255:224]	HMAC key [287:256]
SHA_IDIGEST_B	0x024	Inner digest [95:64]	Inner digest [127:96]	Inner digest [191:160]	Inner digest [223:192]	HMAC key [319:288]
SHA_IDIGEST_C	0x028	Inner digest [63:32]	Inner digest [95:64]	Inner digest [159:128]	Inner digest [191:160]	HMAC key [351:320]
SHA_IDIGEST_D	0x02C	Inner digest [31:0]	Inner digest [63:32]	Inner digest [127:96]	Inner digest [159:128]	HMAC key [383:352]
SHA_IDIGEST_E	0x030		Inner digest[31:0]	Inner digest [95:64]	Inner digest [127:96]	HMAC key [415:384]
SHA_IDIGEST_F	0x034			Inner digest [63:32]	Inner digest [95:64]	HMAC key [447:416]
SHA_IDIGEST_G	0x038			Inner digest [31:0]	Inner digest [63:32]	HMAC key [479:448]
SHA_IDIGEST_H	0x03C				Inner digest[31:0]	HMAC key [511:480]

Note: Inner digests are initial, intermediate, and result digests.

Outer Digest Registers

The **SHA_ODIGEST_A** to **SHA_ODIGEST_H** registers are relevant only for HMAC operations; the contents are ignored for hash operations.

Before writing to the digest registers, the operation must be configured in the **SHA Mode (SHA_MODE)** register. For HMAC operations without key processing, the **HMAC_KEY_PROC** bit must be clear in the **SHA_MODE** register before starting operations. Once the algorithm has been programmed in the **SHA_MODE** register, only the relevant digest registers for the selected algorithm must be written:

- **SHA_ODIGEST_A** to **SHA_ODIGEST_D** registers for MD5
- **SHA_ODIGEST_A** to **SHA_ODIGEST_E** registers for SHA-1
- **SHA_ODIGEST_A** to **SHA_ODIGEST_H** registers for SHA-2 (224 to 256)

When HMAC key processing is enabled (**HMAC_KEY_PROC=1**), these registers must be written with the lower 256 bits of the HMAC key to be processed in little-endian format (first byte of key string in bits [7:0]).

Note: If the HMAC key is less than 512 bits, it must be properly padded with zeros: all 16 HMAC key registers must be written explicitly; the core does not pad. Additionally, if the HMAC key is larger than 512 bits, the host must perform a preprocessing step to reduce it to one 512-bit block. This involves hashing the large key and padding the hash result with zeros until it is 512 bits wide.

The computed outer digest can be read from these registers when the **SHA Interrupt Status (SHA_IRQSTATUS)** register when the **OUTPUT_READY** bit has been set indicating that the operation is done.

Note: If no HMAC key processing is performed, the value read is identical to the value written initially. The MD5 outer digest is available from registers **SHA_ODIGEST_A** to

SHA_ODIGEST_D, the SHA-1 outer digest from registers **SHA_IDIGEST_A** to **SHA_IDIGEST_E**, and the SHA-224 and SHA-256 outer digest from registers **SHA_IDIGEST_A** to **SHA_IDIGEST_H**.

Note: The HMAC key is not preserved. If another block must be authenticated using the same key, the key must be reloaded by the host. If the same key must be used many times, it is advisable to do a HMAC key processing-only pass to obtain the inner and outer digest precomputes and load these precomputes for subsequent passes (only the inner digest must be reloaded if the outer digest is not modified by the host), because this saves two hash blocks worth of computation time.

Inner Digest Registers

The **SHA_IDIGEST_A** to **SHA_IDIGEST_H** registers are used for HMAC and hash operations.

The inner/initial digest for HMAC and hash continue operations (**HMAC_KEY_PROC** = 0 and **ALGO_CONSTANT** = 0) must be written to these registers before starting the operation by writing to the **SHA_MODE** register. Only the relevant digest registers for the selected algorithm must be written:

- **SHA_IDIGEST_A** to **SHA_IDIGEST_D** registers for MD5
- **SHA_IDIGEST_A** to **SHA_IDIGEST_E** registers for SHA-1
- **SHA_IDIGEST_A** to **SHA_IDIGEST_H** registers for SHA-2

When **ALGO_CONSTANT** = 1 in the **SHA_MODE** register, the **SHA Inner Digest n (SHA_IDIGEST_n)** registers do not need to be written by the application because they are overwritten with the appropriate algorithm constants.

When **HMAC_KEY_PROC** is 1, these registers must be written with the upper 256 bits of the HMAC key to be processed in little-endian format (first byte of key string in bits [7:0]).

Note: If the HMAC key is less than 512 bits, it must be properly padded with zeros: all 16 HMAC key registers must be written explicitly; the core does not pad. Additionally, if the HMAC key is larger than 512 bits, the host must perform a preprocessing step to reduce it to one 512-bit block. This involves hashing the large key and padding the hash result with zeros until it is 512 bits wide.

The order of the bytes within the digest is such that it can be fed back unmodified into the little-endian data input when preprocessing HMAC keys larger than 64 bytes, or it can typically be inserted unmodified into a little-endian data stream (for example, IPSEC packets), regardless of the selected algorithm.

Note: The HMAC key or inner digest is not preserved. If another block must be authenticated using the same key, the key or inner digest must be reloaded by the host. If the same key must be used many times, it is advisable to do a HMAC key processing-only pass to obtain the inner and outer digest precomputes and load these precomputes for subsequent passes (only the inner digest must be reloaded if the outer digest is not modified by the host), because this saves two hash blocks worth of computation time.

Closing a Hash

The amount of data to hash is not necessarily a multiple of 64 bytes. The **CLOSE_HASH** bit in the **SHA_MODE** register is set to append padding so that the message size becomes a multiple of 64 bytes. Consequently, a minimum of 9 bytes must be added to the message. Nine bytes is the minimum number of bytes that contains the minimum 65-bit padding specified by FIPS 180-1.

If the size of the last block of data is less than or equal to 55 bytes, no additional 64-byte block is required. However, if the last block of data contains more than 55 bytes, an extra 64-byte block must be added to make the padding as specified by FIPS 180-1. This extra block is added automatically by the hardware; thus, the module is fed with a 64-byte block of data. However, appending a pad on the last block of data can result in the creation of an extra 64-byte block.

The one or two last blocks that contain the padding are processed in the same way as the other blocks. Hash completion is then indicated in the same way as for a new hash, and the hash result can be read in the digest registers. The **SHA_DIGESTCOUNT** register returns restored Digest Count + Length when it is read, and hashing completes.

Assuming a message of 129 bytes, Table 15-5 on page 1072 shows the SHA digest for three passes. Table 15-6 on page 1072 shows the SHA digest for one pass.

Table 15-5. SHA Digest Processed in Three Passes

	Digest (A to E)	SHA_DIGESTCOUNT	SHA_MODE and SHA_LENGTH	SHA_DATA_n_IN
First pass			WRITE: LENGTH=64 ALGO (dependent on the algorithm to apply) ALGO_CONSTANT=1 CLOSE_HASH=0	First 64 bytes of message
Second pass	Round 1 digest calculation	WRITE: 64	WRITE: LENGTH=64 ALGO (dependent on the algorithm to apply) ALGO_CONSTANT=0 CLOSE_HASH=0	Second 64 bytes of message
Third pass	Round 2 digest calculation	WRITE: 128	Write: LENGTH=1 ALGO (dependent on the algorithm to apply) ALGO_CONSTANT=0 CLOSE_HASH=1	Last byte of message
	Final digest	READ: 129		

If the three passes are not performed in succession, the digest registers must be saved and restored for the next use of the SHA/MD5 engine. If the rounds are performed consecutively, there is no need to do anything with the digest registers.

Table 15-6. SHA Digest Processed in One Pass

	Digest (A to E)	SHA_DIGEST_COUNT	SHA_MODE and SHA_LENGTH	SHA_DATA_n_IN
First pass			WRITE: LENGTH=129 ALGO (dependent on the algorithm to apply) ALGO_CONSTANT=1 CLOSE_HASH=1	First 64 bytes of message

Table 15-6. SHA Digest Processed in One Pass (continued)

	Digest (A to E)	SHA_DIGEST_COUNT	SHA_MODE and SHA_LENGTH	SHA_DATA_n_IN
	Round 1 digest calculation			Second 64 bytes of message
	Round 2 digest calculation			Last byte of message
	Final digest	Read: 129		

15.1.5.2 MD5 Mode

Starting a New Hash

To start a new hash, perform the following steps:

1. Set the ALGO bit field in the **SHA_MODE** register to 0x0 to select the MD5 algorithm.
2. Set the ALGO_CONSTANT bit to 1 in the **SHA_MODE** register to initialize all digest registers from **SHA_ODIGEST_A/SHA_IDIGEST_A** to **SHA_ODIGEST_H/SHA_IDIGEST_H** with default values specified by the algorithm, and set the **SHA_DIGESTCOUNT** register to 0.
3. Specify the LENGTH field in the **SHA_LENGTH** register of the hash data to process in bytes.
4. Set the CLOSE_HASH bit in the **SHA_MODE** register to let the SHA/MD5 engine do the padding. If MD5 is computed in one shot, the length of the message can be any value up to . To process an intermediate MD5 digest, the CLOSE_HASH bit is set to 0, in which case packets to be hashed must be 64 bytes; the last packet must be hashed with the CLOSE_HASH bit set to 1.

After the configuration is complete, the hash engine can receive the data to process (the INPUT_READY bit is 1 in the **SHA_IRQSTATUS** register). Data must be written to the 16 x 32-bit **SHA_DATA_n_IN** registers that provide storage for one 64-byte block of data. Unless the CLOSE_HASH bit is set in the **SHA_MODE** register, the **SHA_DATA_n_IN** 64-byte input buffer must be filled. Data can be written by single write transactions to the 16 registers from a processor or by a µDMA transfer.

For a µDMA transfer, the SDAM_EN bit must be set in the **SHA_SYSCONFIG** register before starting the new hash and the µDMA channel for SHA/MD5 0 Data In Request must be configured. The µDMA must be configured to the appropriate hash transfer size. See “Micro Direct Memory Access (µDMA)” on page 705 for more information on programming the µDMA. A µDMA done is asserted after the last **SHA_DATA_n_IN** register is filled..

The module detects that a 64-byte block is available, and then moves the data to a working register space for processing and sets the INPUT_READY bit to 1 in the **SHA_IRQSTATUS** register. If the DMA_EN bit is set in the **SHA_SYSCONFIG** register, then a new µDMA request triggers a new block transfer; otherwise, the processor polls the INPUT_READY bit in the **SHA_IRQSTATUS** register and writes the 16 data words of 32 bits when it equals 1.

This operation repeats until the length of the message to hash is reached. The OUTPUT_READY bit in the **SHA_IRQSTATUS** register then indicates that the hash operation is complete. If the IT_EN bit in the **SHA_SYSCONFIG** register is set, an interrupt (active low) is also generated to indicate the hash completion.

Closing a Hash

The amount of data to hash is not necessarily a multiple of 64 bytes. In this case, the CLOSE_HASH bit in the SHA_MODE register must be set to append padding so that the message size becomes a multiple of 64 bytes. See the previous MD5 algorithm for more information on padding.

The module is fed with a 64-byte block of data, as long as enough data is available. However, a pad is appended on the last block of data. This can result in the creation of an extra 64-byte block.

The one or two last blocks that contain the padding are processed the same way as the other blocks. Hash completion is then indicated the same way as for a new hash, and the 128-bit result can be read in the digest registers. The **SHA_DIGESTCOUNT** register returns restored digest count and length when it is read, and hashing completes.

15.1.5.3 Generating an Software Interrupt

If the **IT_EN** bit is 1 in the **SHA_SYSCONFIG** register, an interrupt is generated at the completion of the hash by the following steps:

1. Receive last block of data (= 64 bytes). (The number of data bytes defined by the **SHA_LENGTH** register is received in the digest registers, from **SHA_ODIGEST_A/SHA_IDIGEST_A** to **SHA_ODIGEST_H/SHA_IDIGEST_H**).
2. If required, apply padding to the last block of data.
3. Hash the last block of data (80 cycles in SHA-1 mode and 64 cycles in MD5, SHA-224, and SHA-256 modes).
4. If required, add an extra 64-byte block of data to complete the padding.
5. Hash this extra block of data (80 cycles in SHA-1 mode and 64 cycles in MD5, SHA-224, and SHA-256 modes).
6. An interrupt is generated (active low).

15.1.6 SHA/MD5 Performance Information

The following table lists the performance for all supported key sizes and modes of operations. It assumed that the engine is kept fully utilized (that is, the host is supplying input block and retrieving output blocks in such a way, that the engine never has to wait for input) and that the previous output has been retrieved before the next output is ready.

Maximum throughput does not include per operation overhead cycles, as the impact on the throughput depends on the size of the block being processed, and would be negligible for large blocks anyway.

Table 15-7. SHA/MD5 Performance

Operation	Algorithm	Cycles per operation	Cycles per block
Hash	MD5	0 / 65	65
	SHA-1	0 / 81	81
	SHA-224	0 / 65	65
	SHA-256	0 / 65	65

Table 15-7. SHA/MD5 Performance (continued)

Operation	Algorithm	Cycles per operation	Cycles per block
HMAC from Key	MD5	196 / 261	65
	SHA-1	244 / 325	81
	SHA-224	196 / 261	65
	SHA-256	196 / 261	65
	MD5	66 / 131	65
HMAC from precomputes	SHA-1	82 / 163	81
	SHA-224	66 / 131	65
	SHA-256	66 / 131	65

Note: An extra block needs to be processed if the length of the data block to be hashed module 64 is 0 or equal to 56.

15.1.7 SHA/MD5 Programming Guide

This section covers the hardware programming sequences for configuration and use of the SHA/MD5 Module.

15.1.7.1 Global Initialization

Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the SHAM is used for the first time after a device reset.

1. When reset has completed, enable the SHA/MD5 Module by setting the R0 bit in the **CRC And Cryptographic Modules Run Mode Clock Gating Control (RCGCCCCM)** register, System Control offset 0x674. When the R0 bit is set in the **CRC and Cryptographic Modules (PRCCM)** register, System Control offset 0xA74 register, the SHA/MD5 Module is powered and ready to be configured.
2. Configure the SHA µDMA channels for Context In, Context Out, Data In, and/or Data Out by programming the appropriate encoding value in the **DMA Channel Map Select n (DMACHMAPn)** register in the µDMA module, offset 0x510. For more information on how to program channel assignments as well as enabling burst and the configured channels, refer to “Micro Direct Memory Access (µDMA)” on page 705.
3. Execute a software reset by setting the SOFTRESET bit in the **SHA_SYSCONFIG** register. When reset is complete, the RESETDONE bit reads as 1 in the **SHA_SYSSTATUS** register.
4. If the SHA channels are configured in the µDMA, enable the required SHA DMA requests by programming bits [9:5] of the **SHA_SYSCONFIG** register, in addition to the completion interrupts in the **SHA DMA Interrupt Mask (SHA_DMAIM)** register, CRC and Cryptographic Modules offset 0x020.

Starting a New HMAC using the SHA-1 Hash Function and HMAC Key Processing

The following procedure is used to begin a new HMAC operation, starting from initial digest values.

1. Load the key value in the **SHA_ODIGEST_A/SHA_IDIGEST_A** to **SHA_ODIGEST_H/SHA_IDIGEST_H** registers.

2. Pad the rest of the SHA_ODIGEST_x and SHA_IDIGEST registers with zeros.
3. Load the message in the **SHA_DATA_n_IN** FIFO registers.
4. Enable HMAC key processing by setting the **HMAC_KEY_PROC** bit in the **SHA_MODE** register.
5. Select the SHA-1 hash function by programming the **ALGO** bit in the **SHA_MODE** register to 0x1.
6. Select the already loaded key by programming the **ALGO_CONSTANT** bit in the **SHA_MODE** register to 0x0.
7. Set the **CLOSE_HASH** bit and the **HMAC_OUTER_HASH** bit in the **SHA_MODE** register so that appropriate padding is inserted and the outer hash is performed immediately after the inner hash has finished.
8. Program the **SHA_LENGTH** register with the block length. Writing this register triggers the HMAC engine to begin processing.

Note: If more than one pass is used during the process (**SHA_MODE[4] CLOSE_HASH == 0x0**), the block length value must be a 64-byte multiple. From this point, three operational modes are possible to continue with the processing: polling, interrupt, and DMA. For more information, see the Operational Modes Configuration section.

Subsequence - Continuing a Prior HMAC Using the SHA-1 Hash Function

The procedure continues a prior HMAC calculation interrupted from a high priority task.

Table 15-8. Continuing a Prior HMAC

Step	Register/Bit Field/Programming Model	Value
Load the initial digest for the used hash algorithm.	SHA_IDIGEST_l[31:0] DATA	-
Restore the digest counter with the value before the switch to the high-priority task.	SHA_DIGEST_COUNT[31:0] COUNT	-
Use the already loaded in the engine key.	SHA_MODE[5] HMAC_KEY_PROC	0x0
Do not use the constants of the selected hash algorithm.	SHA_MODE[3] ALGO_CONSTANT	0x0
Select the SHA-1 hash algorithm.	SHA_MODE[2:1] ALGO	0x1
IF: This is the last 64-byte data block from the input message?	User decision	
Close the hash; an appropriate padding is added.	SHA_MODE[4] CLOSE_HASH	0x1
ENDIF		
Load the block length; this is the trigger to start processing.	SHA_LENGTH[31:0] LENGTH	-

Note: This initial digest is the intermediate digest from the previous calculation before switching to the high priority task. The value is equal to context1 in .

Note: The value is equal to context2 in .

Note: The block length is equal to the context3 value in .

Subsequence - Hashing a Key Bigger than 512 Bits with the SHA-1 Hash Function

The procedure creates a hash value from the key in only one pass.

Table 15-9. SHA-1 Apply on the Key

Step	Register/Bit Field/Programming Model	Value
Load the first part of the key. (Here, the key is like a message.)	SHA_DATA_n_IN (i = 0 to 15)	-
Select the SHA-1 hash function.	SHA_MODE[2:1] ALGO	0x1
Select a new hash operation.	SHA_MODE[3] ALGO_CONSTANT	0x1
Close the hash; the key is processed in single pass.	SHA_MODE[4] CLOSE_HASH	0x1

Operational Modes Configuration

SHA/MD5 Polling Mode

Figure 15-2 on page 1077 shows the SHA/MD5 polling mode. SHA/MD5 polling mode uses the following registers: SHA_IRQSTATUS, SHA_DATA_n_IN, SHA_ODIGEST_A, SHA_DIGEST_COUNT, and SHA_LENGTH.

Figure 15-2. SHA/MD5 Polling Mode

SHA/MD5 Interrupt Mode

The procedure in configures the SHA/MD5 module to work in interrupt-based mode. (For the interrupt subroutine, see the Interrupt Servicing section.)

Table 15-10. Interrupt Mode

Step	Register/Bit Field/Programming Model	Value
Enable the interrupt request to the Cortex-A8 MPU INTC.	SHA_SYSCONFIG[2] IT_EN	0x1

Table 15-10. Interrupt Mode (*continued*)

Step	Register/Bit Field/Programming Model	Value
Load the message length; this is the trigger to start processing.	SHA_LENGTH[31:0] LENGTH	-

SHA/MD5 DMA Mode

The procedure in configures the SHA/MD5 module to work in DMA-based mode.

Table 15-11. DMA Mode

Step	Register/Bit Field/Programming Model	Value
Enable the DMA request to the CDMA controller.	SHA_SYSCONFIG[3] DMA_EN	0x1
Load the message length; this is the trigger to start processing.	SHA_LENGTH[31:0] LENGTH	-

SHA/MD5 Event Servicing**Interrupt Servicing**

This section describes the interrupt event servicing of the module. Figure 15-3 on page 1079 shows the interrupt subroutine. The following registers are used in the SHA/MD5 interrupt routine: SHA_IRQSTATUS, SHA_DATA_n_IN, SHA_ODIGEST_A, SHA_DIGEST_COUNT, SHA_LENGTH, and SHA_IDIGEST_A.

Figure 15-3. SHA/MD5 Interrupt Subroutine

15.2 SHA/MD5 Register Map

Table 15-12 on page 1079 lists the SHA/MD5 registers. The SHA Module comprises registers that exist at an offset relative to the SHA/MD5 Module base address and a small set of SHA/MD5 µDMA interrupt registers that exist at an offset relative to an CRC and Cryptographic Modules base address. The SHA/MD5 Module register offsets are relative to the base address 0x4403.4000. The SHA µDMA offsets are relative to the base address 0x4403.0000.

15.3 SHA/MD5 Register Descriptions

This section describes the SHA/MD5 registers.

Note: The SHA/MD5 registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed and can corrupt register contents.

The first 16 registers of HIB1 are the outer and inner digest registers.

Table 15-13. SHA/MD5 Inner/Outer Digest/HMAC Key Register Mapping

Register Name	Address Offset	MD5 (read/write)	SHA-1 (read/write)	SHA-2 (read/write)		HMAC key proc (write)

PKA Status Register

SHA Outer Digest n (SHA_ODIGEST_n)

Base 0x4403.4000
Offset 0x000
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	DATA	RW	0x0000.0000	Digest/Key Data

Register 17: SHA Digest Count (SHA_DIGEST_COUNT), offset 0x040

This register is written with the initial digest count and can be read to determine the digest count result. Note that for Initial Digest Count writes, bits 5:0 must be zero. This register is written the initial digest byte count when both the HMAC_KEY_PROC bit and the ALGO_CONSTANT bit is zero in the SHA_MODE register. When either the HMAC_KEY_PROC bit or the ALGO_CONSTANT bit is 1, this register does not need to be written because it is overwritten with 64 or 0 automatically. When starting an HMAC operation from precomputes (HMAC_KEY_PROC=0), the value 64 must be written in the **SHA_DIGESTCOUNT** register. Note that the value written should always be a 64 byte multiple, the lower 6 bits written are ignored. The updated digest byte count (initial digest byte count + bytes processed) can be read from this register when the status register indicates that the operation is done or when a µDMA context out is requested.

SHA Digest Count (SHA_DIGEST_COUNT)

Base 0x4403.4000
Offset 0x040
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	COUNT	RW	0x0000.0000	Digest Count This field is written with the initial digest value for bits [31:6] only ([5:0] are assumed to be zeros). When read, this outputs the result/intermediate digest count.

Register 18: SHA Mode (SHA_MODE), offset 0x044

This register is written to configure the hash algorithm to be used in the hash operation.

SHA Mode (SHA_MODE)

Base 0x4403.4000
Offset 0x044
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
7	HMAC_OUTER_HASH	RW	0	<p>HMAC Outer Hash Processing Enable</p> <p>This bit is written to indicate that the outer hash should be performed on the hash digest when the inner hash has finished. The inner hash finishes when the length of hash has been processed the final inner hash is performed (if CLOSE_HASH was set to 1).</p> <p>This bit should normally be set together with CLOSE_HASH to finish the inner hash first, or immediately when block length is zero (HMAC continue with the just outer hash to be done). This bit is auto-cleared when outer hash is finished.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>No operation</td> </tr> <tr> <td>1</td> <td> Enable HMAC processing of outer hash. Register 19: SHA Length (SHA_LENGTH), offset 0x048

WRITE: Block Length/Remaining Byte Count (bytes) **READ:** Remaining Byte Count. The value programmed MUST be a 64-byte multiple if Close Hash is set to 0. This register is also the trigger to start processing: once this register is written, the core will commence requesting input data via DMA or IRQ (if programmed length > 0) and start processing. The remaining byte count for the active operation can be read from this register when the interrupt status register indicates that the operation is suspended due to a context switch request.

SHA Length (SHA_LENGTH)

- Register 34: SHA Data 14 Input (SHA_DATA_14_IN), offset 0x0B8**
- Register 35: SHA Data 15 Input (SHA_DATA_15_IN), offset 0x0BC**

Data input message

Note: The **SHA_DATA_n_IN_0** register acts as a FIFO and shifts data into the other **SHA_DATA_n_IN** registers.

SHA Data n Input (SHA_DATA_n_IN)

Base 0x4403.4000
Offset 0x080
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	DATA_IN	RW	0x0000.0000	Digest/Key Data

Register 36: SHA Revision (SHA_REVISION), offset 0x100

This register provides the unique revision number of the module. This can be used by the driver to determine the capabilities available.

SHA Revision (SHA_REVISION)

Base 0x4403.4000

Offset 0x100

Type RO, reset 0x40000C03

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	REVISION	RO	0x40000C03	Revision Number
------	----------	----	------------	-----------------

This field indicates the revision number of the module.

Register 37: SHA System Configuration (SHA_SYSCONFIG), offset 0x110

System configuration register

Note: After one operation has completed, the **SHA_SYSCONFIG** register must be cleared and re-configured for the next operation to ensure proper µDMA and data operation functionality.

SHA System Configuration (SHA_SYSCONFIG)

Base 0x4403.4000
Offset 0x110
Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	SADVANCED	RW	0	Advanced Mode Enable
	Value	Description		
	0	Legacy mode enabled for the Secure World. In Legacy mode, the Secure World, the context input DMA request, and the result output DMA request are masked. This means that neither DMAREQUEST_CTXIN_S and DMAREQUEST_CTXOUT_S are asserted.		
	1	Advanced mode is enabled. These DMA requests are enabled by bit 3 of this register.		
6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:4	SIDLE	RW	0	Sidle mode

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	RESETDONE	RO	1	Reset done status
		Value	Description	
		0	Reset not complete	
		1	Reset complete	

Register 39: SHA Interrupt Status (SHA_IRQSTATUS), offset 0x118

Interrupt Status Register

SHA Interrupt Status (SHA_IRQSTATUS)

Base 0x4403.4000
Offset 0x118
Type RO, reset 0x0000.0008

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	CONTEXT_READY	RO	1	Context Ready Status
		Value	Description	
		0	The context registers are not available for a new context.	
		1	The context input registers are available for a new context for the next packet to be processed.	
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	INPUT_READY	RO	0	Input Ready Status
		Value	Description	
		0	The Data FIFO is not ready to receive the next 64-byte data block.	
		1	The Data FIFO (SHA_DATA_n_IN registers) is ready to receive the next 64-byte data block.	
0	OUTPUT_READY	RO	0	Output Ready Status
		Value	Description	
		0	No saved context available.	
		1	A saved context is available from the context output registers.	

Register 40: SHA Interrupt Enable (SHA_IRQENABLE), offset 0x11C

The **SHA_IRQENABLE** register contains an enable bit for each unique interrupt. An interrupt is enabled when both the global enable, the **IT_EN** bit, in the **SHA_SYSCONFIG** register and the bit in this register are both set to 1.

SHA Interrupt Enable (SHA_IRQENABLE)

Base 0x4403.4000
Offset 0x11C
Type RW, reset 0x0000.0007

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	M_CONTEXT_READY	RW	0	Mask for context ready interrupt
	Value	Description		
	0	Context ready interrupt is disabled (masked).		
	1	Context ready interrupt is enabled.		
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	M_INPUT_READY	RW	1	Mask for input ready interrupt
	Value	Description		
	0	Input ready interrupt is disabled (masked).		
	1	Input ready interrupt is enabled.		
0	M_OUTPUT_READY	RW	1	Mask for output ready interrupt
	Value	Description		
	0	Output ready interrupt is disabled (masked).		
	1	Output ready interrupt is enabled.		

15.4 SHA/MD5 µDMA Control Register Descriptions (Encryption Control Offset)

This section lists and describes the SHA/MD5 µDMA registers, in numerical order by address offset. Registers in this section are relative to the Encryption Control base address of 0x4403.0000.

Note: The SHA module can only be accessed through privileged mode. If the µDMA is used for SHA transfers, then the µDMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

Note: If the application uses SHA µDMA interrupt triggers, the bits in the **SHA_IRQENABLE** register should be cleared.

Register 41: SHA DMA Interrupt Mask (SHA_DMAIM), offset 0x010

The **SHA DMA Interrupt Mask (SHA_DMA_IM)** register controls interrupt behavior and are used to program which interrupts are suppressed.

SHA DMA Interrupt Mask (SHA_DMAIM)

Base

Offset 0x010

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:3	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
2	COUT	RW	0	<p>Context Out DMA Done Interrupt Mask</p> <p>If this bit is unmasked, an interrupt is generated when the µDMA completes the output context read from the internal register.</p> <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The COUT interrupt is suppressed and not sent to the interrupt controller.</td></tr> <tr> <td>1</td><td>The COUT interrupt is sent to the interrupt controller.</td></tr> </tbody> </table>	Value	Description	0	The COUT interrupt is suppressed and not sent to the interrupt controller.	1	The COUT interrupt is sent to the interrupt controller.
Value	Description									
0	The COUT interrupt is suppressed and not sent to the interrupt controller.									
1	The COUT interrupt is sent to the interrupt controller.									
1	DIN	RW	0	<p>Data In DMA Done Interrupt Mask</p> <p>If this bit is unmasked, an interrupt is generated when the µDMA writes the last word of input data to the internal FIFO of the engine.</p> <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The DIN interrupt is suppressed and not sent to the interrupt controller.</td></tr> <tr> <td>1</td><td>The DIN interrupt is sent to the interrupt controller.</td></tr> </tbody> </table>	Value	Description	0	The DIN interrupt is suppressed and not sent to the interrupt controller.	1	The DIN interrupt is sent to the interrupt controller.
Value	Description									
0	The DIN interrupt is suppressed and not sent to the interrupt controller.									
1	The DIN interrupt is sent to the interrupt controller.									
0	CIN	RW	0	<p>Context In DMA Done Interrupt Mask</p> <p>If this bit is unmasked, an interrupt is generated when the µDMA completes a context write to the internal register.</p> <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The CIN interrupt is suppressed and not sent to the interrupt controller.</td></tr> <tr> <td>1</td><td>The CIN interrupt is sent to the interrupt controller.</td></tr> </tbody> </table>	Value	Description	0	The CIN interrupt is suppressed and not sent to the interrupt controller.	1	The CIN interrupt is sent to the interrupt controller.
Value	Description									
0	The CIN interrupt is suppressed and not sent to the interrupt controller.									
1	The CIN interrupt is sent to the interrupt controller.									

Register 42: SHA DMA Raw Interrupt Status (SHA_DMARIS), offset 0x014

The **SHA DMA Raw Interrupt Status (SHA_DMA_RIS)** register contains the raw interrupt status. If any of these bits read 1, the processor is interrupted if the corresponding masked interrupt status bit is set to '1.'

SHA DMA Raw Interrupt Status (SHA_DMARIS)

Base

Offset 0x014

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	COUT	RW	0	Context Out DMA Done Raw Interrupt Status Value Description 0 No Interrupt. 1 The µDMA has completed the output context read from the internal register and an interrupt has been triggered and is pending.
1	DIN	RW	0	Data In DMA Done Raw Interrupt Status Value Description 0 No Interrupt. 1 The µDMA has written the last word of input data to the internal FIFO of the engine and an interrupt has been triggered and is pending.
0	CIN	RW	0	Context In DMA Done Raw Interrupt Status Value Description 0 No interrupt. 1 The µDMA has completed a context write to the internal register and an interrupt has been triggered and is pending.

Register 43: SHA DMA Masked Interrupt Status (SHA_DMAMIS), offset 0x018

The **SHA DMA Masked Interrupt Status (SHA_DMA_MIS)** register displays the raw interrupts that are unmasked in the **SHA_DMA_RIS** register.

SHA DMA Masked Interrupt Status (SHA_DMAMIS)

Base

Offset 0x018

Type RO, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:3 reserved RO 0x0000.000 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

2 COUT RO 0 Context Out DMA Done Masked Interrupt Status

Value Description

- 0 An interrupt has not occurred or is masked.
- 1 A **COUT** interrupt has occurred.

1 DIN RO 0 Data In DMA Done Masked Interrupt Status

Value Description

- 0 An interrupt has not occurred or is masked.
- 1 A **DIN** interrupt has occurred.

0 CIN RO 0 Context In DMA Done Raw Interrupt Status

Value Description

- 0 An interrupt has not occurred or is masked.
- 1 A **CIN** interrupt has occurred.

Register 44: SHA DMA Interrupt Clear (SHA_DMAIC), offset 0x01C

The **SHA DMA Interrupt Clear** register is used to clear the **SHA_DMA_RIS** and **SHA_DMA_MIS** registers by writing a 1 to each register bit.

Note: This register always reads as zero.

SHA DMA Interrupt Clear (SHA_DMAIC)

0	CIN	W1C	0	Context In DMA Done Raw Interrupt Status Writing a 1 to this bit clears the CIN bit in the SHA_DMA_RIS and SHA_DMA_MIS register..

16 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The TM4C129XKCZAD General-Purpose Timer Module (GPTM) contains 16/32-bit GPTM blocks. Each 16/32-bit GPTM block provides two 16-bit timers/counters (referred to as Timer A and Timer B) that can be configured to operate independently as timers or event counters, or concatenated to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger µDMA transfers.

In addition, timers can be used to trigger analog-to-digital conversions (ADC). The ADC trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The GPT Module is one timing resource available on the Tiva™ C Series microcontrollers. Other timer resources include the System Timer (SysTick) (see 145) and the PWM timer in the PWM module (see “PWM Timer” on page 1933).

The General-Purpose Timer Module (GPTM) contains eight 16/32-bit GPTM blocks with the following functional options:

- Operating modes:
 - 16- or 32-bit programmable one-shot timer
 - 16- or 32-bit programmable periodic timer
 - 16-bit general-purpose timer with an 8-bit prescaler
 - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
 - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
 - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
 - The System Clock or a global Alternate Clock (ALTCLK) resource can be used as timer clock source. The global ALTCLK can be:
 - PIOSC
 - Hibernation Module Real-time clock output (RTCOSC)
 - Low-frequency internal oscillator (LFIOSC)
- Count up or down
- Sixteen 16/32-bit Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)

- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Dedicated channel for each timer
 - Burst request generated on timer interrupt

16.1 Block Diagram

In the block diagram, the specific Capture Compare PWM (CCP) pins available depend on the TM4C129XKCZAD device. See Table 16-1 on page 1101 for the available CCP pins and their timer assignments.

Figure 16-1. GPTM Module Block Diagram

Table 16-1. Available CCP Pins

	Timer B	-	T7CCP1

16.2 Signal Description

The following table lists the external signals of the GP Timer module and describes the function of each. The GP Timer signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these GP Timer signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the GP Timer function. The number in parentheses is the encoding that must be programmed into the **PMCn** field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the GP Timer signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769.

Table 16-2. General-Purpose Timers Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description

16.3 Functional Description

The main components of each GPTM block are two free-running up/down counters (referred to as Timer A and Timer B), two prescaler registers, two match registers, two prescaler match registers, two shadow registers, and two load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface. Timer A and Timer B can be used individually, in which case they have a 16-bit counting range for the 16/32-bit GPTM blocks. In addition, Timer A and Timer B can be concatenated to provide a 32-bit counting range for the 16/32-bit GPTM blocks. Note that the prescaler can only be used when the timers are used individually.

The available modes for each GPTM block are shown in Table 16-3 on page 1104. Note that when counting down in one-shot or periodic modes, the prescaler acts as a true prescaler and contains the least-significant bits of the count. When counting up in one-shot or periodic modes, the prescaler acts as a timer extension and holds the most-significant bits of the count. In input edge count, input

edge time and PWM mode, the prescaler always acts as a timer extension, regardless of the count direction.

Table 16-3. General-Purpose Timer Capabilities

Mode	Timer Use	Count Direction	Counter Size	Prescaler Size ^a
One-shot	Individual	Up or Down	16-bit	8-bit
	Concatenated	Up or Down	32-bit	-
Periodic	Individual	Up or Down	16-bit	8-bit
	Concatenated	Up or Down	32-bit	-
RTC	Concatenated	Up	32-bit	-
Edge Count	Individual	Up or Down	16-bit	8-bit
Edge Time	Individual	Up or Down	16-bit	8-bit
PWM	Individual	Down	16-bit	8-bit

a. The prescaler is only available when the timers are used individually

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 1122), the **GPTM Timer A Mode (GPTMTAMR)** register (see page 1123), and the **GPTM Timer B Mode (GPTMTBMR)** register (see page 1127). When in one of the concatenated modes, Timer A and Timer B can only operate in one mode. However, when configured in an individual mode, Timer A and Timer B can be independently configured in any combination of the individual modes.

16.3.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters Timer A and Timer B are initialized to all 1s, along with their corresponding registers:

- Load Registers:
 - **GPTM Timer A Interval Load (GPTMTAILR)** register (see page 1149)
 - **GPTM Timer B Interval Load (GPTMTBILR)** register (see page 1150)
- Shadow Registers:
 - **GPTM Timer A Value (GPTMTAV)** register (see page 1159)
 - **GPTM Timer B Value (GPTMTBV)** register (see page 1160)

The following prescale counters are initialized to all 0s:

- **GPTM Timer A Prescale (GPTMTAPR)** register (see page 1153)
- **GPTM Timer B Prescale (GPTMTBPR)** register (see page 1154)
- **GPTM Timer A Prescale Snapshot (GPTMTAPS)** register (see page 1162)
- **GPTM Timer B Prescale Snapshot (GPTMTBPS)** register (see page 1163)

16.3.2 Timer Clock Source

The general purpose timer has the capability of being clocked by either the system clock or an alternate clock source. By setting the `ALTCLK` bit in the **GPTM Clock Configuration (GPTMCC)**

register, offset 0xFC8, software can selects an alternate clock source as programmed in the **Alternate Clock Configuration (ALTCLKCFG)** register, offset 0x138 in the System Control Module. The alternate clock source options available are PIOSC, RTCOSC and LFIOSC. Refer to “System Control” on page 230 for additional information.

Note: When the ALTCLK bit is set in the **GPTMCC** register to enable using the alternate clock source, the synchronization imposes restrictions on the starting count value (down-count), terminal value (up-count) and the match value. This restriction applies to all modes of operation. Each event must be spaced by 4 Timer (ALTCLK) clock periods + 2 system clock periods. If some events do not meet this requirement, then it is possible that the timer block may need to be reset for correct functionality to be restored.

Example: ALTCLK= $T_{PIOSC} = 62.5\text{ns}$ (16Mhz Trimmed)

$T_{hclk} = 1\mu\text{s}$ (1Mhz)

$$4 \cdot 62.5\text{ns} + 2 \cdot 1\mu\text{s} = 2.25\mu\text{s}$$

$$2.25\mu\text{s}/62.5\text{ns} = 36 \text{ or } 0x23$$

The minimum values for the periodic or one-shot with a match interrupt enabled are:
GPTMTAMATCHR = 0x23 **GPTMTAILR** = 0x46

16.3.3 Timer Modes

This section describes the operation of the various timer modes. When using Timer A and Timer B in concatenated mode, only the Timer A control and status bits must be used; there is no need to use Timer B control and status bits. The GPTM is placed into individual/split mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 1122). In the following sections, the variable “n” is used in bit field and register names to imply either a Timer A function or a Timer B function. Throughout this section, the timeout event in down-count mode is 0x0 and in up-count mode is the value in the **GPTM Timer n Interval Load (GPTMTnILR)** and the optional **GPTM Timer n Prescale (GPTMTnPR)** registers, with the exception of RTC mode.

16.3.3.1 One-Shot/Periodic Timer Mode

The selection of one-shot or periodic mode is determined by the value written to the **TnMR** field of the **GPTM Timer n Mode (GPTMTnMR)** register (see page 1123). The timer is configured to count up or down using the **TnCDIR** bit in the **GPTMTnMR** register.

When software sets the **TnEN** bit in the **GPTM Control (GPTMCTL)** register (see page 1131), the timer begins counting up from 0x0 or down from its preloaded value. Alternatively, if the **TnWOT** bit is set in the **GPTMTnMR** register, once the **TnEN** bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger Mode” on page 1114). Table 16-4 on page 1105 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-4. Counter Values When the Timer is Enabled in Periodic or One-Shot Modes

Register	Count Down Mode	Count Up Mode
GPTMTnR	GPTMTnILR	0x0
GPTMTnV	GPTMTnILR in concatenated mode; GPTMTnPR in combination with GPTMTnILR in individual mode	0x0
GPTMTnPS	GPTMTnPR in individual mode; not available in concatenated mode	0x0 in individual mode; not available in concatenated mode

When the timer is counting down and it reaches the timeout event (0x0), the timer reloads its start value from the **GPTMTnILR** and the **GPTMTnPR** registers on the next cycle. When the timer is counting up and it reaches the timeout event (the value in the **GPTMTnILR** and the optional

GPTMTnPR registers), the timer reloads with 0x0. If configured to be a one-shot timer, the timer stops counting and clears the **TnEN** bit in the **GPTMCTL** register. If configured as a periodic timer, the timer starts counting again on the next cycle.

In periodic, snap-shot mode (**TnMR** field is 0x2 and the **TnSNAPS** bit is set in the **GPTMTnMR** register), the value of the timer at the time-out event is loaded into the **GPTMTnR** register and the value of the prescaler is loaded into the **GPTMTnPS** register. The free-running counter value is shown in the **GPTMTnV** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry by examining the snapshot values and the current value of the free-running timer. Snapshot mode is not available when the timer is configured in one-shot mode.

In addition to reloading the count value, the GPTM can generate interrupts, CCP outputs and triggers when it reaches the time-out event. The GPTM sets the **TnTORIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 1141), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 1147). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register (see page 1138), the GPTM also sets the **TnTOMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 1144). The time-out interrupt can be disabled entirely by setting the **TACINTD** bit in the **GPTM Timer n Mode (GPTMTnMR)** register. In this case, the **TnTORIS** bit does not even set in the **GPTMRIS** register.

By setting the **TnMIE** bit in the **GPTMTnMR** register, an interrupt condition can also be generated when the Timer value equals the value loaded into the **GPTM Timer n Match (GPTMTnMATCHR)** and **GPTM Timer n Prescale Match (GPTMTnPMR)** registers. This interrupt has the same status, masking, and clearing functions as the time-out interrupt, but uses the match interrupt bits instead (for example, the raw interrupt status is monitored via **TnMRIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register). Note that the interrupt status bits are not updated by the hardware unless the **TnMIE** bit in the **GPTMTnMR** register is set, which is different than the behavior for the time-out interrupt. The ADC trigger is enabled by setting the **TnOTE** bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The μ DMA trigger is enabled by configuring and enabling the appropriate μ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 710.

The **TCACT** field of the **GPTM Timer n Mode (GPTMTnMR)** register can be configured to clear, set or toggle an output on a time-out event.

If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting down, the counter loads the new value on the next clock cycle and continues counting from the new value if the **TnILD** bit in the **GPTMTnMR** register is clear. If the **TnILD** bit is set, the counter loads the new value after the next timeout. If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting up, the timeout event is changed on the next cycle to the new value. If software updates the **GPTM Timer n Value (GPTMTnV)** register while the counter is counting up or down, the counter loads the new value on the next clock cycle and continues counting from the new value. If software updates the **GPTMTnMATCHR** or the **GPTMTnPMR** registers, the new values are reflected on the next clock cycle if the **TnMRSU** bit in the **GPTMTnMR** register is clear. If the **TnMRSU** bit is set, the new value will not take effect until the next timeout.

If the **TnSTALL** bit in the **GPTMCTL** register is set and the **RTCEN** bit is not set in the **GPTMCTL** register, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution. If the **RTCEN** bit is set, it prevents the **TnSTALL** bit from freezing the count when the processor is halted by the debugger.

The following table shows a variety of configurations for a 16-bit free-running timer while using the prescaler. All values assume a 120-MHz clock with $T_c = \text{Pending ns}$ (clock period). The prescaler can only be used when a 16/32-bit timer is configured in 16-bit mode.

Table 16-5. 16-Bit Timer With Prescaler Configurations

Prescale (8-bit value)	# of Timer Clocks (Tc) ^a	Max Time	Units
00000000	1	Pending	ms
00000001	2	Pending	ms
00000010	3	Pending	ms
-----	--	--	--
11111101	254	Pending	ms
11111110	255	Pending	ms
11111111	256	Pending	ms

a. Tc is the clock period.

Timer Compare Action Mode

The timer compare mode is an extension to the GPTM's existing one-shot and periodic modes. This mode can be used when an application requires a pin change state at some time in the future, regardless of the processor state. The compare mode does not operate when the PWM mode is active and is mutually exclusive to the PWM mode. The compare mode is enabled when the TAMR field is set to 0x1 or 0x2 (one-shot or periodic), the TnAMS bit is 0 (capture or compare mode) and the TCACT field is nonzero in the **GPTM Timer n Mode (GPTMTnMR)** register. Depending on the TCACT encoding, the timer can perform a set, clear or toggle on the corresponding CCPn pin when a timer match occurs. In 16-bit mode, the corresponding CCP pin can have an action applied, but when operating in 32-bit mode, the action can only be applied to the even CCP pin.

The TCACT field can be changed while the GPTM is enabled to generate different combinations of actions. For example, during a periodic event, encodings TCACT = 0x6 or 0x7 can be used to force the initial state of the CCPn pin before the first interrupt and following that, TCACT=0x2 and TCACT=0x3 can be used (alternately) to change the sense of the pin for the subsequent toggle, while possible changing load value for the next period.

The time-out interrupts used for one-shot and periodic modes are used in the compare action modes. Thus, the TnTORIS bits in the **GPTMRIS** register are triggered if the appropriate mask bits are set in the **GPTMIM** register.

16.3.3.2 Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the Timer A and Timer B registers are configured as an up-counter. When RTC mode is selected for the first time after reset, the counter is loaded with a value of 0x1. All subsequent load values must be written to the **GPTM Timer n Interval Load (GPTMTnILR)** registers (see page 1149). If the **GPTMTnILR** register is loaded with a new value, the counter begins counting at that value and rolls over at the fixed value of 0xFFFFFFFF. Table 16-6 on page 1107 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-6. Counter Values When the Timer is Enabled in RTC Mode

Register	Count Down Mode	Count Up Mode
GPTMTnR	Not available	0x1
GPTMTnV	Not available	0x1
GPTMTnPS	Not available	Not available

The input clock on a CCP0 input is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1-Hz rate and is passed along to the input of the counter.

When software writes the **TAEN** bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x1. When the current count value matches the preloaded value in the **GPTMTnMATCHR** registers, the GPTM asserts the **RTCRIS** bit in **GPTMRIS** and continues counting until either a hardware reset, or it is disabled by software (clearing the **TAEN** bit). When the timer value reaches the terminal count, the timer rolls over and continues counting up from 0x0. If the RTC interrupt is enabled in **GPTMIMR**, the GPTM also sets the **RTCMIS** bit in **GPTMMIS** and generates a controller interrupt. The status flags are cleared by writing the **RTCCINT** bit in **GPTMICR**.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

In addition to generating interrupts, the RTC can generate a μDMA trigger. The μDMA trigger is enabled by configuring and enabling the appropriate μDMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 710.

16.3.3.3 Input Edge-Count Mode

Note: For rising-edge detection, the input signal must be High for at least two clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the frequency.

In Edge-Count mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper count value stored in the **GPTM Timer n Prescale (GPTMTnPR)** register and the lower bits in the **GPTMTnR** register. In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge-Count mode, the **TnCMR** bit of the **GPTMTnMR** register must be cleared. The type of edge that the timer counts is determined by the **TnEVENT** fields of the **GPTMCTL** register. During initialization in down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted. In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, that the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**. Table 16-7 on page 1108 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-7. Counter Values When the Timer is Enabled in Input Edge-Count Mode

Register	Count Down Mode	Count Up Mode
GPTMTnR	GPTMTnPR in combination with GPTMTnILR	0x0
GPTMTnV	GPTMTnPR in combination with GPTMTnILR	0x0

When software writes the **TnEN** bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements or increments the counter by 1 until the event count matches **GPTMTnMATCHR** and **GPTMTnPMR**. When the counts match, the GPTM asserts the **CnMRIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode match interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnMMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In up-count mode, the current count of the input events is held in both the **GPTMTnR** and **GPTMTnV** registers. In down-count mode, the current count of the input events can be obtained by subtracting the **GPTMTnR** or **GPTMTnV** from the value made up of the **GPTMTnPR** and **GPTMTnILR** register combination.

In addition to generating interrupts, an ADC and/or a μDMA trigger can be generated. The ADC trigger is enabled by setting the **TnOTE** bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The μDMA trigger is enabled by

configuring and enabling the appropriate µDMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 710.

After the match value is reached in down-count mode, the counter is then reloaded using the value in **GPTMTnILR** and **GPTMTnPR** registers, and stopped because the GPTM automatically clears the **TnEN** bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until **TnEN** is re-enabled by software. In up-count mode, the timer is reloaded with 0x0 and continues counting.

Figure 16-2 on page 1109 shows how Input Edge-Count mode works. In this case, the timer start value is set to **GPTMTnILR** =0x000A and the match value is set to **GPTMTnMATCHR** =0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted because the timer automatically clears the **TnEN** bit after the current count matches the value in the **GPTMTnMATCHR** register.

Figure 16-2. Input Edge-Count Mode Example, Counting Down

16.3.3.4 Input Edge-Time Mode

Note: For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Time mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper timer value stored in the **GPTMTnPR** register and the lower bits in the **GPTMTnILR** register. In this mode, the timer is initialized to the value loaded in the **GPTMTnILR** and **GPTMTnPR** registers when counting down and 0x0 when counting up. The timer is capable of capturing three types of events: rising edge, falling edge, or both. The timer is placed into Edge-Time mode by setting the **TnCMR** bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the **TnEVENT** fields of the **GPTMCTL** register. Table 16-8 on page 1110 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-8. Counter Values When the Timer is Enabled in Input Event-Count Mode

Register	Count Down Mode	Count Up Mode
TnR	GPTMTnILR	0x0
TnV	GPTMTnILR	0x0

When software writes the TnEN bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current timer counter value is captured in the **GPTMTnR** and **GPTMTnPS** register and is available to be read by the microcontroller. The GPTM then asserts the CnERIS bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the CnEMIS bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In this mode, the **GPTMTnR** and **GPTMTnPS** registers hold the time at which the selected input event occurred while the **GPTMTnV** register holds the free-running timer value. These registers can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

In addition to generating interrupts, an ADC and/or a μDMA trigger can be generated. The ADC trigger is enabled by setting the TnOTE bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The μDMA trigger is enabled by configuring the appropriate μDMA channel as well as the type of trigger selected in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 710.

After an event has been captured, the timer does not stop counting. It continues to count until the TnEN bit is cleared. When the timer reaches the timeout value, it is reloaded with 0x0 in up-count mode and the value from the **GPTMTnILR** and **GPTMTnPR** registers in down-count mode.

Figure 16-3 on page 1111 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers, and is held there until another rising edge is detected (at which point the new count value is loaded into the **GPTMTnR** and **GPTMTnPS** registers).

Figure 16-3. 16-Bit Input Edge-Time Mode Example

Note: When operating in Edge-time mode, the counter uses a modulo 2^{24} count if prescaler is enabled or 2^{16} , if not. If there is a possibility the edge could take longer than the count, then another timer configured in periodic-timer mode can be implemented to ensure detection of the missed edge. The periodic timer should be configured in such a way that:

- The periodic timer cycles at the same rate as the edge-time timer
- The periodic timer interrupt has a higher interrupt priority than the edge-time timeout interrupt.
- If the periodic timer interrupt service routine is entered, software must check if an edge-time interrupt is pending and if it is, the value of the counter must be subtracted by 1 before being used to calculate the snapshot time of the event.

16.3.3.5 PWM Mode

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a 24-bit down-counter with a start value (and thus period) defined by the **GPTMTnILR** and **GPTMTnPR** registers. In this mode, the PWM frequency and period are synchronous events and therefore guaranteed to be glitch free. PWM mode is enabled with the **GPTMTnMR** register by setting the **TnAMS** bit to 0x1, the **TnCMR** bit to 0x0, and the **TnMR** field to 0x2. Table 16-9 on page 1111 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-9. Counter Values When the Timer is Enabled in PWM Mode

Register	Count Down Mode	Count Up Mode
GPTMTnR	GPTMTnILR	Not available
GPTMTnV	GPTMTnILR	Not available

When software writes the **TnEN** bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0 state. Alternatively, if the **TnWOT** bit is set in the **GPTMTnMR** register, once the **TnEN** bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger”).

Mode" on page 1114). On the next counter cycle in periodic mode, the counter reloads its start value from the **GPTMTnILR** and **GPTMTnPR** registers and continues counting until disabled by software clearing the **TnEN** bit in the **GPTMCTL** register. The timer is capable of generating interrupts based on three types of events: rising edge, falling edge, or both. The event is configured by the **TnEVENT** field of the **GPTMCTL** register, and the interrupt is enabled by setting the **TnPWMIE** bit in the **GPTMTnMR** register. When the event occurs, the **CnERIS** bit is set in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register . If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register , the GPTM also sets the **CnEMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. Note that the interrupt status bits are not updated unless the **TnPWMIE** bit is set.

In addition, when the **TnPWMIE** bit is set and a capture event occurs, the Timer automatically generates triggers to the ADC and DMA if the trigger capability is enabled by setting the **TnOTE** bit in the **GPTMCTL** register and the **CnEDMAEN** bit in the **GPTMDMAEV** register, respectively.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** and **GPTMTnPR** registers (its start state), and is deasserted when the counter value equals the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Software has the capability of inverting the output PWM signal by setting the **TnPWML** bit in the **GPTMCTL** register.

Note: If PWM output inversion is enabled, edge detection interrupt behavior is reversed. Thus, if a positive-edge interrupt trigger has been set and the PWM inversion generates a positive edge, no event-trigger interrupt asserts. Instead, the interrupt is generated on the negative edge of the PWM signal.

Figure 16-4 on page 1113 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and **TnPWML**=0 (duty cycle would be 33% for the **TnPWML**=1 configuration). For this example, the start value is **GPTMTnILR**=0xC350 and the match value is **GPTMTnMATCHR**=0x411A.

Figure 16-4. 16-Bit PWM Mode Example

When synchronizing the timers using the **GPTMSYNC** register, the timer must be properly configured to avoid glitches on the CCP outputs. Both the **TnPLO** and the **TnMRSU** bits must be set in the **GPTMTnMR** register. Figure 16-5 on page 1113 shows how the CCP output operates when the **TnPLO** and **TnMRSU** bits are set and the **GPTMTnMATCHR** value is greater than the **GPTMTnILR** value.

Figure 16-5. CCP Output, GPTMTnMATCHR > GPTMTnILR

Figure 16-6 on page 1114 shows how the CCP output operates when the **PLO** and **MRSU** bits are set and the **GPTMTnMATCHR** value is the same as the **GPTMTnILR** value. In this situation, if the **PLO** bit is 0, the CCP signal goes high when the **GPTMTnILR** value is loaded and the match would be essentially ignored.

Figure 16-6. CCP Output, GPTMTnMATCHR = GPTMTnILR

Figure 16-7 on page 1114 shows how the CCP output operates when the **PLO** and **MRSU** bits are set and the **GPTMTnILR** is greater than the **GPTMTnMATCHR** value.

Figure 16-7. CCP Output, GPTMTnILR > GPTMTnMATCHR

16.3.4 Wait-for-Trigger Mode

The Wait-for-Trigger mode allows daisy chaining of the timer modules such that once configured, a single timer can initiate multiple timing events using the Timer triggers. Wait-for-Trigger mode is enabled by setting the **TnWOT** bit in the **GPTMTnMR** register. When the **TnWOT** bit is set, Timer N+1 does not begin counting until the timer in the previous position in the daisy chain (Timer N) reaches its time-out event. The daisy chain is configured such that GPTM1 always follows GPTM0, GPTM2 follows GPTM1, and so on. If Timer A is configured as a 32-bit (16/32-bit mode) timer (controlled by the **GPTMCFG** field in the **GPTMCFG** register), it triggers Timer A in the next module. If Timer A is configured as a 16-bit (16/32-bit mode) timer, it triggers Timer B in the same module, and Timer B triggers Timer A in the next module. Figure 16-8 on page 1115 shows how the **GPTMCFG** bit affects the daisy chain. This function is valid for one-shot, periodic, and PWM modes.

Note: If the application requires cyclical daisy-chaining, the **TAWOT** bit in the **GPTMTAMR** register of Timer 0 can be set. In this case, Timer 0 waits for a trigger from the last timer module in the chain.

Figure 16-8. Timer Daisy Chain

16.3.5 Synchronizing GP Timer Blocks

The **GPTM Synchronizer Control (GPTMSYNC)** register in the GPTM0 block can be used to synchronize selected timers to begin counting at the same time. Setting a bit in the **GPTMSYNC** register causes the associated timer to perform the actions of a timeout event. An interrupt is not generated when the timers are synchronized. If a timer is being used in concatenated mode, only the bit for Timer A must be set in the **GPTMSYNC** register.

Note: All timers must use the same clock source for this feature to work correctly.

Table 16-10 on page 1115 shows the actions for the timeout event performed when the timers are synchronized in the various timer modes.

Table 16-10. Timeout Actions for GPTM Modes

Mode	Count Dir	Time Out Action
32-bit One-Shot (concatenated timers)	—	N/A
32-bit Periodic (concatenated timers)	Down	Count value = ILR
	Up	Count value = 0
32-bit RTC (concatenated timers)	Up	Count value = 0
16-bit One Shot (individual/split timers)	—	N/A
16-bit Periodic (individual/split timers)	Down	Count value = ILR
	Up	Count value = 0
16-bit Edge-Count (individual/split timers)	Down	Count value = ILR
	Up	Count value = 0
16-bit Edge-Time (individual/split timers)	Down	Count value = ILR
	Up	Count value = 0
16-bit PWM	Down	Count value = ILR

16.3.6 DMA Operation

The timers each have a dedicated µDMA channel and can provide a request signal to the µDMA controller. Pulse requests are generated by a timer via its own `dma_req` signal. A `dma_done` signal is provided from the µDMA to each timer to indicate transfer completion and trigger a µDMA done interrupt (`DMAnRIS`) in the **GPTM Raw Interrupt Status Register (GPTMRIS)** register. The request is a burst type and occurs whenever a timer raw interrupt condition occurs. The arbitration size of the µDMA transfer should be set to the amount of data that should be transferred whenever a timer event occurs.

For example, to transfer 256 items, 8 items at a time every 10 ms, configure a timer to generate a periodic timeout at 10 ms. Configure the µDMA transfer for a total of 256 items, with a burst size of 8 items. Each time the timer times out, the µDMA controller transfers 8 items, until all 256 items have been transferred. Refer to “Micro Direct Memory Access (µDMA)” on page 705 for more details about programming the µDMA controller.

A **GPTM DMA Event (GPTMDMAEV)** register is provided to enable the types of events that can cause a `dma_req` signal assertion by the timer module. Application software can enable a `dma_req` trigger for a match, capture or time-out event for each timer using the **GPTMDMAEV** register. For an individual timer, all active timer trigger events that have been enabled through the **GPTMDMAEV** register are ORed together to create a single `dma_req` pulse that is sent to the µDMA. When the µDMA transfer has completed, a `dma_done` signal is sent to the timer resulting in a `DMAnRIS` bit set in the **GPTMRIS** register.

16.3.7 ADC Operation

The timer has the capability to trigger the ADC when the `TNOTE` bit is set in the **GPTMCTL** register at offset 0x00C. The **GPTM ADC Event (GPTMADCEV)** register is additionally provided so that the type of ADC trigger can be defined. For example, by setting the `CBMADCEN` bit in the **GPTMADCEV** register, a trigger pulse will be sent to the ADC whenever a Capture Match event occurs in GPTM B. Similar to the µDMA operation, all active trigger events that have also been enabled in the **GPTMADCEV** register are ORed together to create an ADC trigger pulse.

16.3.8 Accessing Concatenated 16/32-Bit GPTM Register Values

The GPTM is placed into concatenated mode by writing a 0x0 or a 0x1 to the **GPTMCFG** bit field in the **GPTM Configuration (GPTMCFG)** register. In both configurations, certain 16/32-bit GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM Timer A Interval Load (GPTMTAILR)** register [15:0], see page 1149
- **GPTM Timer B Interval Load (GPTMTBILR)** register [15:0], see page 1150
- **GPTM Timer A (GPTMTAR)** register [15:0], see page 1157
- **GPTM Timer B (GPTMTBR)** register [15:0], see page 1158
- **GPTM Timer A Value (GPTMTAV)** register [15:0], see page 1159
- **GPTM Timer B Value (GPTMTBV)** register [15:0], see page 1160
- **GPTM Timer A Match (GPTMTAMATCHR)** register [15:0], see page 1151
- **GPTM Timer B Match (GPTMTBMATCHR)** register [15:0], see page 1152

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

`GPTMTBILR[15:0]:GPTMTAILR[15:0]`

Likewise, a 32-bit read access to **GPTMTAR** returns the value:

`GPTMTBR[15:0]:GPTMTAR[15:0]`

A 32-bit read access to **GPTMTAV** returns the value:

`GPTMTBV[15:0]:GPTMTAV[15:0]`

16.4 Initialization and Configuration

To use a GPTM, the appropriate **TIMERn** bit must be set in the **RCGCTIMER** register (see page 396). If using any CCP pins, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (see page 398). To find out which GPIO port to enable, refer to Table 31-4 on page 2068. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the CCP signals to the appropriate pins (see page 816 and Table 31-5 on page 2085).

This section shows module initialization and configuration examples for each of the supported timer modes.

16.4.1 One-Shot/Periodic Timer Mode

The GPTM is configured for One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the **TnEN** bit in the **GPTMCTL** register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0000.
3. Configure the **TnMR** field in the **GPTM Timer n Mode Register (GPTMTnMR)**:
 - a. Write a value of 0x1 for One-Shot mode.
 - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the **TnSNAPS**, **TnWOT**, **TnMTE**, and **TnCDIR** bits in the **GPTMTnMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down. In addition, if using CCP pins, the **TCACT** field can be programmed to configure the compare action.
5. Load the start value into the **GPTM Timer n Interval Load Register (GPTMTnILR)**.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the **TnEN** bit in the **GPTMCTL** register to enable the timer and start counting.
8. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

If the `TnMIE` bit in the **GPTMTnMR** register is set, the `RTCRIS` bit in the **GPTMRIS** register is set, and the timer continues counting. In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode reloads the timer and continues counting after the time-out event.

16.4.2 Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on an even CCP input. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the `TAEN` bit is cleared) before making any changes.
2. If the timer has been operating in a different mode prior to this, clear any residual set bits in the **GPTM Timer n Mode (GPTMTnMR)** register before reconfiguring.
3. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0001.
4. Write the match value to the **GPTM Timer n Match Register (GPTMTnMATCHR)**.
5. Set/clear the `RTCEN` and `TnSTALL` bit in the **GPTM Control Register (GPTMCTL)** as needed.
6. If interrupts are required, set the `RTCIM` bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the `TAEN` bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTnMATCHR** register, the GPTM asserts the `RTCRIS` bit in the **GPTMRIS** register and continues counting until Timer A is disabled or a hardware reset. The interrupt is cleared by writing the `RTCCINT` bit in the **GPTMICR** register. Note that if the **GPTMTnILR** register is loaded with a new value, the timer begins counting at this new value and continues until it reaches 0xFFFF.FFFF, at which point it rolls over.

16.4.3 Input Edge-Count Mode

A timer is configured to Input Edge-Count mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to 0x0 and the `TnMR` field to 0x3.
4. Configure the type of event(s) that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.
5. Program registers according to count direction:
 - In down-count mode, the **GPTMTnMATCHR** and **GPTMTnPmR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPmR** registers and the **GPTMTnMATCHR** and **GPTMTnPmR** registers equals the number of edge events that must be counted.
 - In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPmR** registers. Note that when executing an up-count, the value of **GPTMTnPmR** and **GPTMTnILR** must be greater than the value of **GPTMTnPmR** and **GPTMTnMATCHR**.

6. If interrupts are required, set the $CnMIM$ bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
7. Set the $TnEN$ bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
8. Poll the $CnMRIS$ bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the $CnMCINT$ bit of the **GPTM Interrupt Clear (GPTMICR)** register.

When counting down in Input Edge-Count Mode, the timer stops after the programmed number of edge events has been detected. To re-enable the timer, ensure that the $TnEN$ bit is cleared and repeat Step #4 on page 1118 through #9 on page 1119.

16.4.4 Input Edge Time Mode

A timer is configured to Input Edge Time mode by the following sequence:

1. Ensure the timer is disabled (the $TnEN$ bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the $TnCMR$ field to 0x1 and the $TnMR$ field to 0x3 and select a count direction by programming the $TnCDIR$ bit.
4. Configure the type of event that the timer captures by writing the $TnEVENT$ field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. If interrupts are required, set the $CnEIM$ bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the $TnEN$ bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
9. Poll the $CnERIS$ bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the $CnECINT$ bit of the **GPTM Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register and clearing the $TnILD$ bit in the **GPTMTnMR** register. The change takes effect at the next cycle after the write.

16.4.5 PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the $TnEN$ bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the $TnAMS$ bit to 0x1, the $TnCMR$ bit to 0x0, and the $TnMR$ field to 0x2.

4. Configure the output state of the PWM signal (whether or not it is inverted) in the `TnPWML` field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. If PWM interrupts are used, configure the interrupt condition in the `TnEVENT` field in the **GPTMCTL** register and enable the interrupts by setting the `TnPWMIE` bit in the **GPTMTnMR** register. Note that edge detect interrupt behavior is reversed when the PWM output is inverted (see page 1131).
7. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
8. Load the **GPTM Timer n Match (GPTMTnMATCHR)** register with the match value.
9. Set the `TnEN` bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Time mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

16.5 Register Map

Table 16-11 on page 1120 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- 16/32-bit Timer 0: 0x4003.0000
- 16/32-bit Timer 1: 0x4003.1000
- 16/32-bit Timer 2: 0x4003.2000
- 16/32-bit Timer 3: 0x4003.3000
- 16/32-bit Timer 4: 0x4003.4000
- 16/32-bit Timer 5: 0x4003.5000
- 16/32-bit Timer 6: 0x400E.0000
- 16/32-bit Timer 7: 0x400E.1000

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 396). There must be a delay of 3 system clocks after the Timer module clock is enabled before any Timer module registers are accessed.

Table 16-11. Timers Register Map

16.6 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

Register 1: GPTM Configuration (GPTMCFG), offset 0x000

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

Important: Bits in this register should only be changed when the TAEN and TBEN bits in the **GPTMCTL** register are cleared.

GPTM Configuration (GPTMCFG)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

16/32-bit Timer 3 base: 0x4003.3000

16/32-bit Timer 4 base: 0x4003.4000

16/32-bit Timer 5 base: 0x4003.5000

16/32-bit Timer 6 base: 0x400E.0000

16/32-bit Timer 7 base: 0x400E.1000

Offset 0x000

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	GPTMCFG	RW	0x0	GPTM Configuration The GPTMCFG values are defined as follows:
		Value	Description	
		0x0	For a 16/32-bit timer, this value selects the 32-bit timer configuration.	
		0x1	For a 16/32-bit timer, this value selects the 32-bit real-time clock (RTC) counter configuration.	
		0x2-0x3	Reserved	
		0x4	For a 16/32-bit timer, this value selects the 16-bit timer configuration. The function is controlled by bits 1:0 of GPTMTAMR and GPTMTBMR .	
		0x5-0x7	Reserved	

Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TAAMS** bit, clear the **TACMR** bit, and configure the **TAMR** field to 0x1 or 0x2.

This register controls the modes for Timer A when it is used individually. When Timer A and Timer B are concatenated, this register controls the modes for both Timer A and Timer B, and the contents of **GPTMTBMR** are ignored.

Important: Except for the **TCACT** bit field, all other bits in this register should only be changed when the **TAEN** bit in the **GPTMCTL** register is cleared.

GPTM Timer A Mode (GPTMTAMR)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

16/32-bit Timer 3 base: 0x4003.3000

16/32-bit Timer 4 base: 0x4003.4000

16/32-bit Timer 5 base: 0x4003.5000

16/32-bit Timer 6 base: 0x400E.0000

16/32-bit Timer 7 base: 0x400E.1000

Offset 0x04

Type RW, reset 0x0000.0000

Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TBAMS** bit, clear the **TBCMR** bit, and configure the **TBMR** field to 0x1 or 0x2.

This register controls the modes for Timer B when it is used individually. When Timer A and Timer B are concatenated, this register is ignored and **GPTMTAMR** controls the modes for both Timer A and Timer B.

Important: Except for the **TCACT** bit field, all other bits in this register should only be changed when the **TBEN** bit in the **GPTMCTL** register is cleared.

GPTM Timer B Mode (GPTMTBMR)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

16/32-bit Timer 3 base: 0x4003.3000

16/32-bit Timer 4 base: 0x4003.4000

16/32-bit Timer 5 base: 0x4003.5000

16/32-bit Timer 6 base: 0x400E.0000

16/32-bit Timer 7 base: 0x400E.1000

Offset 0x008

Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

Important: Bits in this register should only be changed when the **TnEN** bit for the respective timer is cleared.

		0x3		A timeout event for both Timer A and Timer B of GPTM0 is triggered.

Register 6: GPTM Interrupt Mask (GPTMIMR), offset 0x018

This register allows software to enable/disable GPTM controller-level interrupts. Setting a bit enables the corresponding interrupt, while clearing a bit disables it.

GPTM Interrupt Mask (GPTMIMR)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

Value	Description									
0	Interrupt is disabled.									
1	Interrupt is enabled.									

Register 7: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

Note: The state of the **GPTMRIS** register is not affected by disabling and then re-enabling the timer using the TnEN bits in the **GPTM Control (GPTMCTL)** register. If an application requires that all or certain status bits should not carry over after re-enabling the timer, then the appropriate bits in the **GPTMRIS** register should be cleared using the **GPTMICR** register prior to re-enabling the timer. If this is not done, any status bits set in the **GPTMRIS** register and unmasked in the **GPTMIMR** register generate an interrupt once the timer is re-enabled.

GPTM Raw Interrupt Status (GPTMRIS)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

Register 8: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register shows the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

GPTM Masked Interrupt Status (GPTMMIS)

Register 10: GPTM Timer A Interval Load (GPTMTAILR), offset 0x028

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Interval Load (GPTMTBILR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

GPTM Timer A Interval Load (GPTMTAILR)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

16/32-bit Timer 3 base: 0x4003.3000

16/32-bit Timer 4 base: 0x4003.4000

16/32-bit Timer 5 base: 0x4003.5000

16/32-bit Timer 6 base: 0x400E.0000

16/32-bit Timer 7 base: 0x400E.1000

Offset 0x028

Type RW, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	TAILR	RW	0xFFFF.FFFF	GPTM Timer A Interval Load Register Writing this field loads the counter for Timer A. A read returns the current value of GPTMTAILR.

Register 11: GPTM Timer B Interval Load (GPTMTBILR), offset 0x02C

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAILR** register. Reads from this register return the current value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the load value. Bits 31:16 are reserved in both cases.

GPTM Timer B Interval Load (GPTMTBILR)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

Type RW, reset 0x0000.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	TBILR	RW	0x0000.FFFF	GPTM Timer B Interval Load Register Writing this field loads the counter for Timer B. A read returns the current value of GPTMTBILR . When a 16/32-bit GPTM is in 32-bit mode, writes are ignored, and reads return the current value of GPTMTBILR .

Register 12: GPTM Timer A Match (GPTMTAMATCHR), offset 0x030

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTAILR**, determines the duty cycle of the output PWM signal.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAMATCHR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Match (GPTMTBMATCHR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBMATCHR**.

GPTM Timer A Match (GPTMTAMATCHR)

Bit/Field	Name	Type	Reset	Description
31:0	TAMR	RW	0xFFFF.FFFF	GPTM Timer A Match Register
				This value is compared to the GPTMTAR register to determine match events.

Register 13: GPTM Timer B Match (GPTMTBMATCHR), offset 0x034

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTBILR** determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTBILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTBILR**, determines the duty cycle of the output PWM signal.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAMATCHR** register. Reads from this register return the current match value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the match value. Bits 31:16 are reserved in both cases.

GPTM Timer B Match (GPTMTBMATCHR)

				This value is compared to the GPTMTBR register to determine match events.

Register 14: GPTM Timer A Prescale (GPTMTAPR), offset 0x038

This register allows software to extend the range of the timers when they are used individually. When in one-shot or periodic down count modes, this register acts as a true prescaler for the timer counter. When acting as a true prescaler, the prescaler counts down to 0 before the value in the **GPTMTAR** and **GPTMTAV** registers are incremented. In all other individual/split modes, this register is a linear extension of the upper range of the timer counter, holding bits 23:16 in the 16-bit modes of the 16/32-bit GPTM.

GPTM Timer A Prescale (GPTMTAPR)

16/32-bit Timer 0 base: 0x4003.0000

Register 18: GPTM Timer A (GPTMTAR), offset 0x048

This register shows the current value of the Timer A counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B (GPTMTBR)** register). In the 16-bit Input Edge Count, Input Edge Time, and PWM modes, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTAV** register. To read the value of the prescalar in periodic snapshot mode, read the **Timer A Prescale Snapshot (GPTMTAPS)** register.

GPTM Timer A (GPTMTAR)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

16/32-bit Timer 3 base: 0x4003.3000

Bit/Field	Name	Type	Reset	Description
31:0	TAR	RO	0xFFFF.FFFF	GPTM Timer A Register A read returns the current value of the GPTM Timer A Count Register , in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Register 19: GPTM Timer B (GPTMTBR), offset 0x04C

This register shows the current value of the Timer B counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAR** register. Reads from this register return the current value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler in Input Edge Count, Input Edge Time, and PWM modes, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTBV** register. To read the value of the prescalar in periodic snapshot mode, read the **Timer B Prescale Snapshot (GPTMTBPS)** register.

GPTM Timer B (GPTMTBR)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

16/32-bit Timer 3 base: 0x4003.3000

Offset 0x04C

Type RO, reset 0x0000.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	TBR	RO	0x0000.FFFF	GPTM Timer B Register A read returns the current value of the GPTM Timer B Count Register , in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

Register 20: GPTM Timer A Value (GPTMTAV), offset 0x050

When read, this register shows the current, free-running value of Timer A in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry when using the snapshot feature with the periodic operating mode. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAV** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Value (GPTMTBV)** register). In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

GPTM Timer A Value (GPTMTAV)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

Bit/Field	Name	Type	Reset	Description
31:0	TAV	RW	0xFFFF.FFFF	GPTM Timer A Value A read returns the current, free-running value of Timer A in all modes. When written, the value written into this register is loaded into the GPTMTAR register on the next clock cycle.

Note: In 16-bit mode, only the lower 16-bits of the **GPTMTAV** register can be written with a new value. Writes to the prescaler bits have no effect.

Register 21: GPTM Timer B Value (GPTMTBV), offset 0x054

When read, this register shows the current, free-running value of Timer B in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry. When written, the value written into this register is loaded into the **GPTMTBR** register on the next clock cycle.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAV** register. Reads from this register return the current free-running value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

Description

31:0	TBV	RW	0x0000.FFFF	GPTM Timer B Value
------	-----	----	-------------	--------------------

A read returns the current, free-running value of Timer A in all modes. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

Note: In 16-bit mode, only the lower 16-bits of the **GPTMTBV** register can be written with a new value. Writes to the prescaler bits have no effect.

Register 22: GPTM RTC Predivide (GPTMRTCPD), offset 0x058

This register provides the current RTC predivider value when the timer is operating in RTC mode. Software must perform an atomic access with consecutive reads of the **GPTMTAR**, **GPTMTBR**, and **GPTMRTCPD** registers.

Note: When an alternate clock source is enabled, a read of this register returns the current count -1.

GPTM RTC Predivide (GPTMRTCPD)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

	Value Description			
	0	The alternate clock source (ALTCLK) is not available to the Timer module.		
	1	The alternate clock source (ALTCLK) is available to the Timer module.		
5	SYNCCNT	RO	0x1	Synchronize Start
	Value Description			
	0	Timer is not capable of synchronizing the counter value with other GPTimers.		
	1	Timer is capable of synchronizing the counter value with other Timers.		
4	CHAIN	RO	0x1	Chain with Other Timers
	Value Description			
	0	Timer is not capable of chaining with the previously numbered Timer.		
	1	Timer is capable of chaining with the previously numbered Timer.		
	Note that although this bit is set for Timer 0A, this timer cannot chain because there is not a previously numbered Timer.			

Bit/Field	Name	Type	Reset	Description
3:0	SIZE	RO	0x0	Count Size
Value Description				
	0			Timer A and Timer B counters are 16 bits each with an 8-bit prescale counter.
	1			Timer A and Timer B counters are 32 bits each with a 16-bit prescale counter.

Register 28: GPTM Clock Configuration (GPTMCC), offset 0xFC8

The **GPTMCC** register controls the clock source for the General-Purpose Timer module.

Note: When the **ALTCLK** bit is set in the **GPTMCC** register to enable using the alternate clock source, the synchronization imposes restrictions on the starting count value (down-count), terminal value (up-count) and the match value. This restriction applies to all modes of operation. Each event must be spaced by 4 Timer (ALTCLK) clock periods + 2 system clock periods. If some events do not meet this requirement, then it is possible that the timer block may need to be reset for correct functionality to be restored.

Example: ALTCLK= $T_{PIOSC} = 62.5\text{ns}$ (16Mhz Trimmed)

$T_{hclk} = 1\mu\text{s}$ (1Mhz)

$$4 \times 62.5\text{ns} + 2 \times 1\mu\text{s} = 2.25\mu\text{s}$$

$$2.25\mu\text{s}/62.5\text{ns} = 36 \text{ or } 0x23$$

The minimum values for the periodic or one-shot with a match interrupt enabled are:

GPTMTAMATCHR = 0x23 **GPTMTAILR** = 0x46

GPTM Clock Configuration (GPTMCC)

0	ALTCLK	RW	0x0	Alternate Clock Source
		Value	Description	
		0	System clock (based on clock source and divisor factor programmed in RSCLKCFG register in the System Control Module)	
		1	Alternate clock source as defined by ALTCLKCFG register in System Control Module.	

17 Watchdog Timers

A watchdog timer can generate a non-maskable interrupt (NMI), a regular interrupt or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way. The TM4C129XKCZAD microcontroller has two Watchdog Timer Modules, one module is clocked by the system clock (Watchdog Timer 0) and the other (Watchdog Timer 1) is clocked by the clock source programmed in the **ALTCLK** field of the **Alternate Clock Configuration (ALTCLKCFG)** register, System Control offset 0x138. The two modules are identical except that WDT1 is in a different clock domain, and therefore requires synchronizers. As a result, WDT1 has a bit defined in the **Watchdog Timer Control (WDTCTL)** register to indicate when a write to a WDT1 register is complete. Software can use this bit to ensure that the previous access has completed before starting the next access.

The TM4C129XKCZAD controller has two Watchdog Timer modules with the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

17.1 Block Diagram

Figure 17-1. WDT Module Block Diagram

17.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. The watchdog interrupt can be programmed to be a non-maskable interrupt (NMI) using the INTTYPE bit in the **WDTCTL** register. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled by setting the RESEN bit in the **WDTCTL** register, the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

The watchdog timer is disabled by default out of reset. To achieve maximum watchdog protection of the device, the watchdog timer can be enabled at the start of the reset vector.

17.2.1 Register Access Timing

Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The **WRC** bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for **WRC=1** prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock.

17.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the **Rn** bit in the **Watchdog Timer Run Mode Clock Gating Control (RCGCWD)** register, see page 395.

The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If WDT1, wait for the **WRC** bit in the **WDTCTL** register to be set.
3. Set the **INTEN** bit (if interrupts are required) or the **RESEN** bit (if a reset is required after two timeouts) in the **WDTCTL** register. The Watchdog Timer starts when either of them is enabled.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

To service the watchdog, periodically reload the count value into the **WDTLOAD** register to restart the count. The interrupt can be enabled using the **INTEN** bit in the **WDTCTL** register to allow the processor to attempt corrective action if the watchdog is not serviced often enough. The **RESEN** bit in **WDTCTL** can be set so that the system resets if the failure is not recoverable using the ISR.

Note: The application should be sure not to modify the **ALTCLK** encoding in the **ALTCLKCFG** register while the WDT1 is enabled and running.

17.4 Register Map

Table 17-1 on page 1176 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address:

- WDT0: 0x4000.0000
- WDT1: 0x4000.1000

Note that the Watchdog Timer module clock must be enabled before the registers can be programmed (see page 395).

Table 17-1. Watchdog Timers Register Map

Offset	Name	Type	Reset	Description	See page
0x000	WDTLOAD	RW	0xFFFF.FFFF	Watchdog Load	1177

0xFFC	WDTPCellID3	RO	0x0000.00B1	Watchdog PrimeCell Identification 3	1197

17.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

Register 1: Watchdog Load (WDTLOAD), offset 0x000

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

Watchdog Load (WDTLOAD)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x000

Type RW, reset 0xFFFF.FFFF

Bit/Field Name Type Reset Description

31:0	WDTLOAD	RW	0xFFFF.FFFF	Watchdog Load Value
------	---------	----	-------------	---------------------

Register 2: Watchdog Value (WDTVALUE), offset 0x004

This register contains the current count value of the timer.

Watchdog Value (WDTVALUE)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x004

Type RO, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	WDTVALUE	RO	0xFFFF.FFFF	Watchdog Value Current value of the 32-bit down counter.
------	----------	----	-------------	---

Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled by setting the **INTEN** bit, all subsequent writes to the **INTEN** bit are ignored. The only mechanisms that can re-enable writes to this bit are a hardware reset or a software reset initiated by setting the appropriate bit in the **Watchdog Timer Software Reset (SRWD)** register.

Important: Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The **WRC** bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for **WRC=1** prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock and therefore does not have a **WRC** bit.

Watchdog Control (WDTCTL)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x008

Type RW, reset 0x0000.0000 (WDT0) and 0x8000.0000 (WDT1)

Bit/Field	Name	Type	Reset	Description
31	WRC	RO	1	Write Complete The WRC values are defined as follows: Value Description 0 A write access to one of the WDT1 registers is in progress. 1 A write access is not in progress, and WDT1 registers can be read or written. Note: This bit is reserved for WDT0 and has a reset value of 0.
30:3	reserved	RO	0x000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description						
2	INTTYPE	RW	0	<p>Watchdog Interrupt Type</p> <p>The INTTYPE values are defined as follows:</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Watchdog interrupt is a standard interrupt.</td></tr> <tr> <td>1</td><td>Watchdog interrupt is a non-maskable interrupt.</td></tr> </tbody> </table>	Value	Description	0	Watchdog interrupt is a standard interrupt.	1	Watchdog interrupt is a non-maskable interrupt.
Value	Description									
0	Watchdog interrupt is a standard interrupt.									
1	Watchdog interrupt is a non-maskable interrupt.									
1	RESEN	RW	0	<p>Watchdog Reset Enable</p> <p>The RESEN values are defined as follows:</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Disabled.</td></tr> <tr> <td>1</td><td>Enable the Watchdog module reset output. Setting this bit enables the Watchdog Timer.</td></tr> </tbody> </table>	Value	Description	0	Disabled.	1	Enable the Watchdog module reset output. Setting this bit enables the Watchdog Timer.
Value	Description									
0	Disabled.									
1	Enable the Watchdog module reset output. Setting this bit enables the Watchdog Timer.									
0	INTEN	RW	0	<p>Watchdog Interrupt Enable</p> <p>The INTEN values are defined as follows:</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Interrupt event disabled. Once this bit is set, it can only be cleared by a hardware reset or a software reset initiated by setting the appropriate bit in the Watchdog Timer Software Reset (SRWD) register.</td></tr> <tr> <td>1</td><td>Interrupt event enabled. Once enabled, all writes are ignored. Setting this bit enables the Watchdog Timer.</td></tr> </tbody> </table>	Value	Description	0	Interrupt event disabled. Once this bit is set, it can only be cleared by a hardware reset or a software reset initiated by setting the appropriate bit in the Watchdog Timer Software Reset (SRWD) register.	1	Interrupt event enabled. Once enabled, all writes are ignored. Setting this bit enables the Watchdog Timer.
Value	Description									
0	Interrupt event disabled. Once this bit is set, it can only be cleared by a hardware reset or a software reset initiated by setting the appropriate bit in the Watchdog Timer Software Reset (SRWD) register.									
1	Interrupt event enabled. Once enabled, all writes are ignored. Setting this bit enables the Watchdog Timer.									

Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Write to this register when a watchdog time-out interrupt has occurred to properly service the Watchdog. Value for a read or reset is indeterminate.

Note: Locking the watchdog registers by using the **WDTLOCK** register does not affect the **WDTICR** register and allows interrupts to always be serviced. Thus, a write at any time of the **WDTICR** register clears the **WDTMIS** register and reloads the 32-bit counter from the **WDTLOAD** register. The **WDTICR** register should only be written when interrupts have triggered and need to be serviced.

Watchdog Interrupt Clear (WDTICR)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x00C

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	WDTINTCLR	WO	-	Watchdog Interrupt Clear A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the WDTLOAD register. Write to this register when a watchdog time-out interrupt has occurred to properly service the Watchdog. Value for a read or reset is indeterminate.

Register 5: Watchdog Raw Interrupt Status (WDTRIS), offset 0x010

This register is the raw interrupt status register. Watchdog interrupt events can be monitored via this register if the controller interrupt is masked.

Watchdog Raw Interrupt Status (WDTRIS)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x010

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	WDTRIS	RO	0	Watchdog Raw Interrupt Status
		Value	Description	
		0	The watchdog has not timed out.	
		1	A watchdog time-out event has occurred.	

Register 6: Watchdog Masked Interrupt Status (WDTMIS), offset 0x014

This register is the masked interrupt status register. The value of this register is the logical AND of the raw interrupt bit and the Watchdog interrupt enable bit.

Watchdog Masked Interrupt Status (WDTMIS)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x014

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	WDTMIS	RO	0	Watchdog Masked Interrupt Status
		Value	Description	
		0	The watchdog has not timed out or the watchdog timer interrupt is masked.	
		1	A watchdog time-out event has been signalled to the interrupt controller.	

Register 7: Watchdog Test (WDTTEST), offset 0x418

This register provides user-enabled stalling when the microcontroller asserts the CPU halt flag during debug.

Watchdog Test (WDTTEST)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x418

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	STALL	RW	0	Watchdog Stall Enable
		Value	Description	
		0	The watchdog timer continues counting if the microcontroller is stopped with a debugger.	
		1	If the microcontroller is stopped with a debugger, the watchdog timer stops counting. Once the microcontroller is restarted, the watchdog timer resumes counting.	
7:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers, except for the **Watchdog Test (WDTTEST)** register. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

Watchdog Lock (WDTLOCK)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0xC00

Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0 WDTLOCK RW 0x0000.0000 Watchdog Lock

A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value re-applies the lock, preventing any register updates, except for the **WDTTEST** register. Avoid writes to the **WDTTEST** register when the watchdog registers are locked.

A read of this register returns the following values:

Value	Description
0x0000.0001	Locked
0x0000.0000	Unlocked

Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

Watchdog Peripheral Identification 4 (WDTPeriphID4)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0xFD0

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PID4	RO	0x00	WDT Peripheral ID Register [7:0]

Register 10: Watchdog Peripheral Identification 5 (WDTPeriphID5), offset 0xFD4

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

Watchdog Peripheral Identification 5 (WDTPeriphID5)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0xFD4

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

18 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. Two identical converter modules are included, which share 24 input channels.

The TM4C129XKCZAD ADC module features 12-bit conversion resolution and supports 24 input channels, plus an internal temperature sensor. Each ADC module contains four programmable sequencers allowing the sampling of multiple analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. In addition, the conversion value can optionally be diverted to a digital comparator module. Each ADC module provides eight digital comparators. Each digital comparator evaluates the ADC conversion value against its two user-defined values to determine the operational range of the signal. The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. A phase shifter can delay the start of sampling by a specified phase angle. When using both ADC modules, it is possible to configure the converters to start the conversions coincidentally or within a relative phase from each other, see “Sample Phase Control” on page 1205.

The TM4C129XKCZAD microcontroller provides two ADC modules with each having the following features:

- 24 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of one million samples/second
- Optional, programmable phase delay
- Sample and hold window programmability
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
 - Controller (software)
 - Timers
 - Analog Comparators
 - PWM
 - GPIO
- Hardware averaging of up to 64 samples
- Eight digital comparators

- Converter uses two external reference signals (VREFA+ and VREFA-) or VDDA and GND_A as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Dedicated channel for each sample sequencer
 - ADC module uses burst requests for DMA
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate ADC clock

18.1 Block Diagram

The TM4C129XKCZAD microcontroller contains two identical Analog-to-Digital Converter modules. These two modules, ADC0 and ADC1, share the same 24 analog input channels. Each ADC module operates independently and can therefore execute different sample sequences, sample any of the analog input channels at any time, and generate different interrupts and triggers. Figure 18-1 on page 1199 shows how the two modules are connected to analog inputs and the system bus.

Figure 18-1. Implementation of Two ADC Blocks

Figure 18-2 on page 1200 provides details on the internal configuration of the ADC controls and data registers.

Figure 18-2. ADC Module Block Diagram

18.2 Signal Description

The following table lists the external signals of the ADC module and describes the function of each. The **AINx** signals are analog functions for some GPIO signals. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the ADC signals. These signals are configured by clearing the corresponding **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding **AMSEL** bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769. The **VREFA+** and **VREFA-** signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function and are not 5-V tolerant.

Table 18-1. ADC Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
AIN0	G2	PE3	I	Analog	Analog-to-digital converter input 0.
AIN1	G1	PE2	I	Analog	Analog-to-digital converter input 1.
AIN2	H2	PE1	I	Analog	Analog-to-digital converter input 2.
AIN3	H3	PE0	I	Analog	Analog-to-digital converter input 3.
AIN4	B2	PD7	I	Analog	Analog-to-digital converter input 4.
AIN5	B3	PD6	I	Analog	Analog-to-digital converter input 5.
AIN6	B4	PD5	I	Analog	Analog-to-digital converter input 6.
AIN7	A4	PD4	I	Analog	Analog-to-digital converter input 7.

Table 18-1. ADC Signals (212BGA) (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
AIN8	B5	PE5	I	Analog	Analog-to-digital converter input 8.
AIN9	A5	PE4	I	Analog	Analog-to-digital converter input 9.
AIN10	C6	PB4	I	Analog	Analog-to-digital converter input 10.
AIN11	B6	PB5	I	Analog	Analog-to-digital converter input 11.
AIN12	D1	PD3	I	Analog	Analog-to-digital converter input 12.
AIN13	D2	PD2	I	Analog	Analog-to-digital converter input 13.
AIN14	C1	PD1	I	Analog	Analog-to-digital converter input 14.
AIN15	C2	PD0	I	Analog	Analog-to-digital converter input 15.
AIN16	J1	PK0	I	Analog	Analog-to-digital converter input 16.
AIN17	J2	PK1	I	Analog	Analog-to-digital converter input 17.
AIN18	K1	PK2	I	Analog	Analog-to-digital converter input 18.
AIN19	K2	PK3	I	Analog	Analog-to-digital converter input 19.
AIN20	A7	PE6	I	Analog	Analog-to-digital converter input 20.
AIN21	B7	PE7	I	Analog	Analog-to-digital converter input 21.
AIN22	A8	PP7	I	Analog	Analog-to-digital converter input 22.
AIN23	B8	PP6	I	Analog	Analog-to-digital converter input 23.
VREFA+	F4	fixed	-	Analog	A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 32-44 on page 2134.
VREFA-	G5	fixed	-	Analog	A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 32-44 on page 2134.

18.3 Functional Description

The TM4C129XKCZAD ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence. In addition, the µDMA can be used to more efficiently move data from the sample sequencers without CPU intervention.

18.3.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 18-2 on page 1202 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. Each sample that is captured is stored in the FIFO. In this implementation, each FIFO entry is a 32-bit word, with the lower 12 bits containing the conversion result.

Table 18-2. Samples and FIFO Depth of Sequencers

Sequencer	Number of Samples	Depth of FIFO
SS3	1	1
SS2	4	4
SS1	4	4
SS0	8	8

For a given sample sequence, each sample is defined by bit fields in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)**, **ADC Sample Sequence Extended Input Multiplexer Select (ADCSSEMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn** and **ADCSSEMUXn** fields select the input pin, while the **ADCSSCTLn** fields contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASENn** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register and should be configured before being enabled. Sampling is then initiated by setting the **SSn** bit in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. In addition, sample sequences may be initiated on multiple ADC modules simultaneously using the **GSYNC** and **SYNCWAIT** bits in the **ADCPSSI** register during the configuration of each ADC module. For more information on using these bits, refer to page 1249.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence are allowed. In the **ADCSSCTLn** register, the **IEn** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END** bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFOOn)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTATn)** registers along with **FULL** and **EMPTY** status flags. If a write is attempted when the FIFO is full, the write does not occur and an overflow condition is indicated. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

18.3.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- DMA operation

- Sequence prioritization
- Trigger configuration
- Comparator configuration
- External voltage reference
- Sample phase control
- Module clocking

18.3.2.1 Interrupts

The register configurations of the sample sequencers and digital comparators dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the MASK bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIS)** register, which shows the raw status of the various interrupt signals; and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the **ADCIM** register. Sequencer interrupts are cleared by writing a 1 to the corresponding IN bit in **ADCISC**. Digital comparator interrupts are cleared by writing a 1 to the **ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)** register.

18.3.2.2 DMA Operation

DMA may be used to increase efficiency by allowing each sample sequencer to operate independently and transfer data without processor intervention or reconfiguration.

The ADC asserts single and burst µDMA request signals (`dma_sreq` and `dma_req`) to the µDMA controller based on the FIFO level. The `dma_req` signal is generated when the FIFO in question is half-full (that is, at 4 samples for SS0, 2 samples for SS1 and SS2, and at 1 sample for SS3). If, for example, the **ADCSSCTL0** register has six samples to transfer, a burst of four values occurs followed by two single transfers (`dma_sreq`). The `dma_done` signals (one per sample sequencer) are sent to the ADC to allow for a triggering of `DMAINRn` interrupt bits in the **ADCRIS** register. The µDMA is enabled for a specific sample sequencer by setting the appropriate `ADENn` bit in the **ADCACTSS** register at offset 0x000.

To use the µDMA with the ADC module, the application must enable the ADC channel through **DMA Channel Map Select n (DMACHMAPn)** register in the µDMA.

Refer to the “Micro Direct Memory Access (µDMA)” on page 705 for more details about programming the µDMA controller.

18.3.2.3 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

18.3.2.4 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. Trigger sources include processor (default), analog comparators, an external signal on a GPIO specified by the **GPIO ADC Control (GPIOADCCTL)** register, a GP Timer, a

PWM generator, and continuous sampling. The processor triggers sampling by setting the **SSx** bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

Care must be taken when using the continuous sampling trigger. If a sequencer's priority is too high, it is possible to starve other lower priority sequencers. Generally, a sample sequencer using continuous sampling should be set to the lowest priority. Continuous sampling can be used with a digital comparator to cause an interrupt when a particular voltage is seen on an input.

18.3.2.5 Sample and Hold Window Control

The ADC module provides the capability of programming the sample and hold window of each step in a sequence through the **ADC Sample Sequence n Sample and Hold Time (ADCSSTSHn)** register. Each **TSHn** field can be written with a different sample and hold width, which is represented in ADC clocks. The table below gives the allowed encodings:

Table 18-3. Sample and Hold Width in ADC Clocks

TSHn Encoding	N _{SH}
0x0	4
0x1	reserved
0x2	8
0x3	reserved
0x4	16
0x5	reserved
0x6	32
0x7	reserved
0x8	64
0x9	reserved
0xA	128
0xB	reserved
0xC	256
0xD-0xF	reserved

Since both source resistance and conversion frequency are functions of the sample and hold number (N_{SH}), the system designer must evaluate how changing this value can effect system performance. Source resistance can be calculated by the following equation:

$$R_S = ((N_{SH} * T_{ADC})/C_{ADC} * \ln(2^N)) - R_{ADC}$$

where:

- N_{SH} is the number of ADC conversion clock periods in the sample time
- T_{ADC} is the ADC conversion clock period, which is 1/16 MHz for 1 Msps
- C_{ADC} is the ADC equivalent input capacitance, which equals 10 pF
- N is the resolution which is 12-bits
- R_{ADC} is the ADC equivalent input resistance which is 2.5 kΩ

Conversion frequency can be calculated using the following equation:

$$F_{CONV} = 1 / ((N_{SH} + 12) * T_{ADC})$$

where:

- N_{SH} is the number of ADC conversion clock periods in the sample time
- T_{ADC} is the ADC conversion clock period, which is 1/16 MHz for 1 Msps

These two equations show that when N_{SH} is increased, F_{CONV} is reduced and R_S is increased:

Table 18-4. R_S and F_{CONV} Values with Varying N_{SH} Values and $T_{ADC} = 1/16$ MHz

N_{SH}	4	8	16	32	64	128	256
R_S (Ω)	506	3,511	9,522	21,545	45,590	93,680	189,859
F_{CONV} (Ksps)	1000	800	571	364	211	114	60

The system designer must take into consideration both of these factors for optimal ADC operation.

18.3.2.6 Sample Phase Control

The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. If the converters are running at the same sample rate, they may be configured to start the conversions coincidentally or one ADC may be programmed to lag up to 15 clock cycles relative to the other ADC. The sample time can be delayed from the standard sampling time by programming the **PHASE** field in the **ADC Sample Phase Control (ADCSPC)** register. Figure 18-3 on page 1205 shows an example of various phase relationships at a 1 Msps rate.

Figure 18-3. ADC Sample Phases

This feature can be used to double the sampling rate of an input. Both ADC Module 0 and ADC Module 1 can be programmed to sample the same input. ADC module 0 can sample at the standard position (the **PHASE** field in the **ADCSPC** register is 0x0). ADC Module 1 can be configured to sample with a phase lag (**PHASE** is nonzero). For a sample rate of samples/second at , the **TSHn** field of all of the sequencer samples of both ADCs must be programmed to 0x0 and the **PHASE** field of one of the ADC modules must be set to 0x8. The two modules can be synchronized using the **GSYNC** and **SYNCWAIT** bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. Software can then combine the results from the two modules to create a sample rate of one million samples/second at 16MHz as shown in Figure 18-4 on page 1206.

Figure 18-4. Doubling the ADC Sample Rate

Using the **ADCSPC** register, ADC0 and ADC1 may provide a number of interesting applications:

- Coincident continuous sampling of different signals. The sample sequence steps run coincidentally in both converters. In this situation, the **TSHn** of matching sample steps of both ADC module sequencers must be the same and the **PHASE** field must be 0x0 in both ADC module **ADCSPC** registers. The **TSHn** field is found in the **ADC Sample Sequence n Sample and Hold Time (ADCSSTSHn)** register.
 - ADC Module 0, **ADCSPC** = 0x0, sampling AIN0
 - ADC Module 1, **ADCSPC** = 0x0, sampling AIN1
- Skewed sampling of the same signal. The skew is determined by both the **TSHn** field in the **ADCSSTSHn** registers and the **PHASE** field in the **ADCSPC** register. For the fastest skewed sample rate, all **TSHn** fields must be programmed to 0x0. If **TSHn**=0x0 for all sequencers and the **PHASE** field of one ADC is 0x8, the configuration doubles the conversion bandwidth of a single input when software combines the results as shown in Figure 18-5 on page 1207.
 - ADC Module 0, **ADCSPC** = 0x0, sampling AIN0
 - ADC Module 1, **ADCSPC** = 0x8, sampling AIN0

Note that it is not required that the **TSHn** fields be the same in a skewed sample. If an application has varying analog input resistance, then **TSHn** and **PHASE** may vary according to operational requirements.

Figure 18-5. Skewed Sampling

18.3.2.7 Module Clocking

The ADC digital block is clocked by the system clock and the ADC analog block is clocked from a separate conversion clock (ADC Clock). The ADC clock frequency can be up to 32 MHz to generate a conversion rate of 2 Msps. A 16 MHz ADC clock provides a 1 Msps sampling rate. There are three sources of the ADC clock:

- Divided PLL VCO. The PLL VCO frequency can be configured to generate up to a 32-MHz clock for a conversion rate of 2 Msps. The CS field in the **ADCCC** register must be programmed to 0x0 to select the PLL VCO and the CLKDIV field is used to set the appropriate clock divisor for the desired frequency.
- 16 MHz PIOSC. Using the PIOSC provides a conversion rate near 1 Msps. To use the PIOSC to clock the ADC, first power up the PLL and then enable the PIOSC in the CS bit field in the **ADCCC** register, then disable the PLL.
- MOSC. The MOSC clock source must be 16 MHz for a 1 Msps conversion rate and 32 MHz for a 2 Msps conversion rate.

The system clock must be at the same frequency or higher than the ADC clock. All ADC modules share the same clock source to facilitate the synchronization of data samples between conversion units, the selection and programming of which is provided by ADC0's **ADCCC** register. The ADC modules do not run at different conversion rates.

18.3.2.8 Busy Status

The **BUSY** bit of the **ADCACTSS** register is used to indicate when the ADC is busy with a current conversion. When there are no triggers pending which may start a new conversion in the immediate cycle or next few cycles, the **BUSY** bit reads as 0. Software must read the status of the **BUSY** bit as clear before disabling the ADC clock by writing to the **Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC)** register.

18.3.2.9 Dither Enable

The **ADCCTL** register provides a dither enable bit to reduce random noise in ADC sampling. The **DITHER** bit is enabled by default at reset. Dither mode can be disabled by clearing the **DITHER** bit in the **ADDCCTL** register.

18.3.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off, and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 1251). A single averaging circuit has been implemented, thus all input channels receive the same amount of averaging whether they are single-ended or differential.

Figure 18-6 shows an example in which the **ADCSAC** register is set to 0x2 for 4x hardware oversampling and the **IE1** bit is set for the sample sequence, resulting in an interrupt after the second averaged value is stored in the FIFO.

Figure 18-6. Sample Averaging Example

18.3.4 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module uses a Successive Approximation Register (SAR) architecture to deliver a 12-bit, low-power, high-precision conversion value. The successive approximation uses a switched capacitor array to perform the dual functions of sampling and holding the signal as well as providing the 12-bit DAC operation.

Figure 18-7 shows the ADC input equivalency diagram; for parameter values, see “Analog-to-Digital Converter (ADC)” on page 2134.

Figure 18-7. ADC Input Equivalency Diagram

The ADC operates from both the 3.3-V analog and 1.2-V digital power supplies. The ADC clock can be configured to reduce power consumption when ADC conversions are not required (see “System Control” on page 250). The analog inputs are connected to the ADC through specially balanced input paths to minimize the distortion and cross-talk on the inputs. Detailed information on the ADC power supplies and analog inputs can be found in “Analog-to-Digital Converter (ADC)” on page 2134.

18.3.4.1 Voltage Reference

The ADC uses internal signals VREFP and VREFN as references to produce a conversion value from the selected analog input. VREFP can be connected to either VREFA+ or VDDA and VREFN can be connected to either VREFA- or GNDA as configured by the VREF bit in the **ADC Control (ADCCTL)** register, as shown in Figure 18-8.

Figure 18-8. ADC Voltage Reference

The range of this conversion value is from 0x000 to 0xFFFF. In single-ended-input mode, the 0x000 value corresponds to the voltage level on VREFN; the 0xFFFF value corresponds to the voltage level on VREFP. This configuration results in a resolution that can be calculated using the following equation:

$$\text{mV per ADC code} = (\text{VREFP} - \text{VREFN}) / 4096$$

While the analog input pads can handle voltages beyond this range, the analog input voltages must remain within the limits prescribed by Table 32-44 on page 2134 to produce accurate results. The $V_{\text{REFA}+}$ and $V_{\text{REFA}-}$ specifications define the useful range for the external voltage references on $V_{\text{REFA}+}$ and $V_{\text{REFA}-}$, see Table 32-44 on page 2134. Care must be taken to supply a reference voltage of acceptable quality. Figure 18-9 on page 1211 shows the ADC conversion function of the analog inputs.

Figure 18-9. ADC Conversion Result

18.3.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the D_n bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** register. Differential pair 0 samples analog inputs 0 and 1; differential pair 1 samples analog inputs 2 and 3; and so on (see Table 18-5 on page 1211). The ADC does not support other differential pairings such as analog input 0 with analog input 3.

Table 18-5. Differential Sampling Pairs

Differential Pair	Analog Inputs
0	0 and 1
1	2 and 3
2	4 and 5
3	6 and 7
4	8 and 9
5	10 and 11
6	12 and 13

Table 18-5. Differential Sampling Pairs (continued)

Differential Pair	Analog Inputs
7	14 and 15
8	16 and 17
9	18 and 19
10	20 and 21
11	22 and 23

The voltage sampled in differential mode is the difference between the odd and even channels:

- Input Positive Voltage: V_{IN_EVEN} = V_{IN_EVEN} (even channel)
- Input Negative Voltage: V_{IN_ODD} = V_{IN_ODD} (odd channel)

The input differential voltage is defined as: $V_{IN_D} = V_{IN+} - V_{IN-}$, therefore:

- If $V_{IN_D} = 0$, then the conversion result = 0x800
- If $V_{IN_D} > 0$, then the conversion result > 0x800 (range is 0x800–0xFFFF)
- If $V_{IN_D} < 0$, then the conversion result < 0x800 (range is 0–0x800)

When using differential sampling, the following definitions are relevant:

- Input Common Mode Voltage: $V_{IN_{CM}} = (V_{IN+} + V_{IN-}) / 2$
- Reference Positive Voltage: V_{REFP}
- Reference Negative Voltage: V_{REFN}
- Reference Differential Voltage: $V_{REF_D} = V_{REFP} - V_{REFN}$
- Reference Common Mode Voltage: $V_{REF_{CM}} = (V_{REFP} + V_{REFN}) / 2$

The following conditions provide optimal results in differential mode:

- Both V_{IN_EVEN} and V_{IN_ODD} must be in the range of (V_{REFP} to V_{REFN}) for a valid conversion result
- The maximum possible differential input swing, or the maximum differential range, is: $-V_{REF_D}$ to $+V_{REF_D}$, so the maximum peak-to-peak input differential signal is $(+V_{REF_D} - -V_{REF_D}) = 2 * V_{REF_D}$ = $2 * (V_{REFP} - V_{REFN})$
- In order to take advantage of the maximum possible differential input swing, $V_{IN_{CM}}$ should be very close to $V_{REF_{CM}}$, see Table 32-44 on page 2134.

If $V_{IN_{CM}}$ is not equal to $V_{REF_{CM}}$, the differential input signal may clip at either maximum or minimum voltage, because either single ended input can never be larger than V_{REFP} or smaller than V_{REFN} , and it is not possible to achieve full swing. Thus any difference in common mode between the input voltage and the reference voltage limits the differential dynamic range of the ADC.

Because the maximum peak-to-peak differential signal voltage is $2 * (V_{REFP} - V_{REFN})$, the ADC codes are interpreted as:

$$\text{mV per ADC code} = (2 * (\text{VREFP} - \text{VREFN})) / 4096$$

Figure 18-10 shows how the differential voltage, ΔV , is represented in ADC codes.

Figure 18-10. Differential Voltage Representation

18.3.6 Internal Temperature Sensor

The temperature sensor serves two primary purposes: 1) to notify the system that internal temperature is too high or low for reliable operation and 2) to provide temperature measurements for calibration of the Hibernate module RTC trim value.

The temperature sensor does not have a separate enable, because it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC. In addition, the temperature sensor has a second power-down input in the 3.3 V domain which provides control by the Hibernation module.

The internal temperature sensor converts a temperature measurement into a voltage. This voltage value, V_{TSENS} , is given by the following equation (where TEMP is the temperature in °C):

$$V_{TSENS} = 2.7 - ((TEMP + 55) / 75)$$

This relation is shown in Figure 18-11 on page 1214.

Figure 18-11. Internal Temperature Sensor Characteristic

The temperature sensor reading can be sampled in a sample sequence by setting the `TSn` bit in the **ADCSSCTLn** register. The sample and hold width should be configured for at least 16 ADC clocks using the **ADCSSSTSHn** register. The temperature reading from the temperature sensor can also be given as a function of the ADC value. The following formula calculates temperature (TEMP in °C) based on the ADC reading (ADC_{CODE} , given as an unsigned decimal number from 0 to 4095) and the maximum ADC voltage range (VREFP - VREFN):

$$TEMP = 147.5 - ((75 * (VREFP - VREFN) * ADC_{CODE}) / 4096)$$

18.3.7 Digital Comparator Unit

An ADC is commonly used to sample an external signal and to monitor its value to ensure that it remains in a given range. To automate this monitoring procedure and reduce the amount of processor overhead that is required, each module provides eight digital comparators.

Conversions from the ADC that are sent to the digital comparators are compared against the user programmable limits in the **ADC Digital Comparator Range (ADCDCCMPn)** registers. The ADC can be configured to generate an interrupt depending on whether the ADC is operating within the low, mid or high-band region configured in the `ADCDCCMPn` bit fields. The digital comparators four operational modes (Once, Always, Hysteresis Once, Hysteresis Always) can be additionally applied to the interrupt configuration.

18.3.7.1 Output Functions

ADC conversions can either be stored in the ADC Sample Sequence FIFOs or compared using the digital comparator resources as defined by the `SnDCOP` bits in the **ADC Sample Sequence n Operation (ADCSSOPn)** register. These selected ADC conversions are used by their respective digital comparator to monitor the external signal. Each comparator has two possible output functions: processor interrupts and triggers.

Each function has its own state machine to track the monitored signal. Even though the interrupt and trigger functions can be enabled individually or both at the same time, the same conversion

data is used by each function to determine if the right conditions have been met to assert the associated output.

Interrupts

The digital comparator interrupt function is enabled by setting the **CIE** bit in the **ADC Digital Comparator Control (ADCDCCTL_n)** register. This bit enables the interrupt function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, and the **DCONSS_x** bit is set in the **ADCIM** register, an interrupt is sent to the interrupt controller.

Note: For a 1 Msps rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the μDMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the μDMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

Note: Only a single **DCONSS_n** bit should be set at any given time. Setting more than one of these bits results in the **INRDC** bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

Triggers

The digital comparator trigger function is enabled by setting the **CTE** bit in the **ADCDCCTL_n** register. This bit enables the trigger function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, the corresponding digital comparator trigger to the PWM module is asserted.

18.3.7.2 Operational Modes

Four operational modes are provided to support a broad range of applications and multiple possible signaling requirements: Always, Once, Hysteresis Always, and Hysteresis Once. The operational mode is selected using the **CIM** or **CTM** field in the **ADCDCCTL_n** register.

Always Mode

In the Always operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria. The result is a string of assertions on the interrupt or trigger while the conversions are within the appropriate range.

Once Mode

In the Once operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria, and the previous ADC conversion value did not. The result is a single assertion of the interrupt or trigger when the conversions are within the appropriate range.

Hysteresis-Always Mode

The Hysteresis-Always operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Always mode, the associated interrupt or trigger is asserted in the following cases: 1) the ADC conversion value meets its comparison criteria or 2) a previous ADC conversion value has met the comparison criteria, and the hysteresis condition has not been cleared by entering the opposite region. The result is a string of assertions on the interrupt or trigger that continue until the opposite region is entered.

Hysteresis-Once Mode

The Hysteresis-Once operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Once mode, the associated interrupt or trigger is asserted only when the ADC conversion value meets its comparison criteria, the hysteresis condition is clear, and the previous ADC conversion did not meet the comparison criteria. The result is a single assertion on the interrupt or trigger.

18.3.7.3 Function Ranges

The two comparison values, COMP0 and COMP1, in the **ADC Digital Comparator Range (ADCDCCMPn)** register effectively break the conversion area into three distinct regions. These regions are referred to as the low-band (less than COMP0), mid-band (greater than COMP0 but less than or equal to COMP1), and high-band (greater than or equal to COMP1) regions. COMP0 and COMP1 may be programmed to the same value, effectively creating two regions, but COMP1 must always be greater than or equal to the value of COMP0. A COMP1 value that is less than COMP0 generates unpredictable results.

Low-Band Operation

To operate in the low-band region, the CIC field or the CTC field in the **ADCDCCCTLn** register must be programmed to 0x0. This setting causes interrupts or triggers to be generated in the low-band region as defined by the programmed operational mode. An example of the state of the interrupt/trigger signal in the low-band region for each of the operational modes is shown in Figure 18-12 on page 1216. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 18-12. Low-Band Operation (CIC=0x0 and/or CTC=0x0)

Mid-Band Operation

To operate in the mid-band region, the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x1. This setting causes interrupts or triggers to be generated in the mid-band region according the operation mode. Only the Always and Once operational modes are available in the mid-band region. An example of the state of the interrupt/trigger signal in the mid-band region for each of the allowed operational modes is shown in Figure 18-13 on page 1217. Note that a "0" in a column following the operational mode name (Always or Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 18-13. Mid-Band Operation (CIC=0x1 and/or CTC=0x1)

High-Band Operation

To operate in the high-band region, the CIC field or the CTC field in the **ADCDCCTLn** register must be programmed to 0x3. This setting causes interrupts or triggers to be generated in the high-band region according the operation mode. An example of the state of the interrupt/trigger signal in the high-band region for each of the allowed operational modes is shown in Figure 18-14 on page 1218. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 18-14. High-Band Operation (CIC=0x3 and/or CTC=0x3)

18.4 Initialization and Configuration

18.4.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps: enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock using the **RCGCADC** register (see page 412).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 398). To find out which GPIO ports to enable, refer to “Signal Description” on page 1200.
3. Set the GPIO AFSEL bits for the ADC input pins (see page 799). To determine which GPIOs to configure, see Table 31-4 on page 2068.
4. Configure the **AIN_x** signals to be analog inputs by clearing the corresponding **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register (see page 810).
5. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 815) in the associated GPIO block.
6. If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

18.4.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization because each sample sequencer is completely programmable.

The configuration for each sample sequencer should be as follows:

1. Ensure that the sample sequencer is disabled by clearing the corresponding ASENn bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
2. Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
3. When using a PWM generator as the trigger source, use the **ADC Trigger Source Select (ADCTSSEL)** register to specify in which PWM module the generator is located. The default register reset selects PWM module 0 for all generators.
4. For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUXn** and **ADCSSEMUXn** registers.
5. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTLn** register. When programming the last nibble, ensure that the **END** bit is set. Failure to set the **END** bit causes unpredictable behavior.
6. If interrupts are to be used, set the corresponding **MASK** bit in the **ADCIM** register.
7. Enable the sample sequencer logic by setting the corresponding ASENn bit in the **ADCACTSS** register.

18.5 Register Map

Table 18-6 on page 1219 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to that ADC module's base address of:

- ADC0: 0x4003.8000
- ADC1: 0x4003.9000

Note that the ADC module clock must be enabled before the registers can be programmed (see page 412). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

18.6 Register Descriptions

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

ADC Active Sample Sequencer (ADCACTSS)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x000

Type RW, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															BUSY
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved				ADEN3	ADEN2	ADEN1	ADENO	reserved				ASEN3	ASEN2	ASEN1	ASENO
Type	RO	RO	RO	RO	RW	RW	RW	RW	RO	RO	RO	RO	RW	RW	RW	RW
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	BUSY	RO	0	ADC Busy
		Value	Description	
	0	ADC is idle		
	1	ADC is busy		
		Note:	In order to use the BUSY bit, the ADC Event Multiplexer Select (ADCEMUX) register must be programmed such that no trigger is selected (bit field encoding is 0xE). The NEVER encoding in the ADCEMUX register allows the ADC to safely be put in Deep-Sleep mode.	
15:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	ADEN3	RW	0	ADC SS3 DMA Enable
		Value	Description	
	0	DMA for Sample Sequencer 3 is disabled.		
	1	DMA for Sample Sequencer 3 is enabled.		
10	ADEN2	RW	0	ADC SS2 DMA Enable
		Value	Description	
	0	DMA for Sample Sequencer 2 is disabled.		
	1	DMA for Sample Sequencer 2 is enabled.		

Bit/Field	Name	Type	Reset	Description
9	ADEN1	RW	0	ADC SS1 DMA Enable Value Description 0 DMA for Sample Sequencer 1 is disabled. 1 DMA for Sample Sequencer 1 is enabled.
8	ADENO	RW	0	ADC SS1 DMA Enable Value Description 0 DMA for Sample Sequencer 1 is disabled. 1 DMA for Sample Sequencer 1 is enabled.
7:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ASEN3	RW	0	ADC SS3 Enable Value Description 0 Sample Sequencer 3 is disabled. 1 Sample Sequencer 3 is enabled.
2	ASEN2	RW	0	ADC SS2 Enable Value Description 0 Sample Sequencer 2 is disabled. 1 Sample Sequencer 2 is enabled.
1	ASEN1	RW	0	ADC SS1 Enable Value Description 0 Sample Sequencer 1 is disabled. 1 Sample Sequencer 1 is enabled.
0	ASEN0	RW	0	ADC SS0 Enable Value Description 0 Sample Sequencer 0 is disabled. 1 Sample Sequencer 0 is enabled.

Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without sending the interrupts to the interrupt controller.

ADC Raw Interrupt Status (ADCRIS)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x004

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	INRDC	RO	0	Digital Comparator Raw Interrupt Status
		Value	Description	
		0	All bits in the ADCDCISC register are clear.	
		1	At least one bit in the ADCDCISC register is set, meaning that a digital comparator interrupt has occurred.	
15:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	DMAINR3	RO	0	SS3 DMA Raw Interrupt Status
		Value	Description	
		0	The DMA interrupt has not occurred.	
		1	The sample sequence 3 DMA interrupt is asserted.	
		This bit is cleared by writing a 1 to the DMAINR3 bit in the ADCISC register.		
10	DMAINR2	RO	0	SS2 DMA Raw Interrupt Status
		Value	Description	
		0	The DMA interrupt has not occurred.	
		1	The sample sequence 2 DMA interrupt is asserted.	
		This bit is cleared by writing a 1 to the DMAINR2 bit in the ADCISC register.

This bit is cleared by writing a 1 to the IN0 bit in the ADCISC register.										

Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the sample sequencer and digital comparator raw interrupt signals are sent to the interrupt controller. Each raw interrupt signal can be masked independently.

Note: For a 1 Msps rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the µDMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the µDMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

Note: Only a single DCONSSn bit should be set at any given time. Setting more than one of these bits results in the **INRDC** bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

2	MASK2	RW	0	SS2 Interrupt Mask Value Description 0 The status of Sample Sequencer 2 does not affect the SS2 interrupt status. 1 The raw interrupt signal from Sample Sequencer 2 (ADCRIS register INR2 bit) is sent to the interrupt controller.
1	MASK1	RW	0	SS1 Interrupt Mask Value Description 0 The status of Sample Sequencer 1 does not affect the SS1 interrupt status. 1 The raw interrupt signal from Sample Sequencer 1 (ADCRIS register INR1 bit) is sent to the interrupt controller.
0	MASK0	RW	0	SS0 Interrupt Mask Value Description 0 The status of Sample Sequencer 0 does not affect the SS0 interrupt status. 1 The raw interrupt signal from Sample Sequencer 0 (ADCRIS register INR0 bit) is sent to the interrupt controller.

Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequencer interrupt conditions and shows the status of interrupts generated by the sample sequencers and the digital comparators which have been sent to the interrupt controller. When read, each bit field is the logical AND of the respective INR and MASK bits. Sample sequencer interrupts are cleared by writing a 1 to the corresponding bit position. Digital comparator interrupts are cleared by writing a 1 to the appropriate bits in the **ADCDCISC** register. If software is polling the **ADCRIS** instead of generating interrupts, the sample sequence INRn bits are still cleared via the **ADCISC** register, even if the INn bit is not set.

Bit/Field	Name	Type	Reset	Description
1	IN1	RW1C	0	SS1 Interrupt Status and Clear Value Description 0 No interrupt has occurred or the interrupt is masked. 1 Both the INR1 bit in the ADCRIS register and the MASK1 bit in the ADCIM register are set, providing a level-based interrupt to the interrupt controller. This bit is cleared by writing a 1. Clearing this bit also clears the INR1 bit in the ADCRIS register.
0	IN0	RW1C	0	SS0 Interrupt Status and Clear Value Description 0 No interrupt has occurred or the interrupt is masked. 1 Both the INR0 bit in the ADCRIS register and the MASK0 bit in the ADCIM register are set, providing a level-based interrupt to the interrupt controller. This bit is cleared by writing a 1. Clearing this bit also clears the INR0 bit in the ADCRIS register.

Register 5: ADC Overflow Status (ADCOSTAT), offset 0x010

This register indicates overflow conditions in the sample sequencer FIFOs. Once the overflow condition has been handled by software, the condition can be cleared by writing a 1 to the corresponding bit position.

ADC Overflow Status (ADCOSTAT)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x010

Type RW1C, reset 0x0000.0000

31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										
3	OV3	RW1C	0	SS3 FIFO Overflow										

Value Description

- 0 The FIFO has not overflowed.
- 1 The FIFO for Sample Sequencer 3 has hit an overflow condition, meaning that the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped.

This bit is cleared by writing a 1.

2	OV2	RW1C	0	SS2 FIFO Overflow
---	-----	------	---	-------------------

Value Description

- 0 The FIFO has not overflowed.
- 1 The FIFO for Sample Sequencer 2 has hit an overflow condition, meaning that the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped.

This bit is cleared by writing a 1.

1	OV1	RW1C	0	SS1 FIFO Overflow
---	-----	------	---	-------------------

Value Description

- 0 The FIFO has not overflowed.
- 1 The FIFO for Sample Sequencer 1 has hit an overflow condition, meaning that the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped.

This bit is cleared by writing a 1.

Bit/Field	Name	Type	Reset	Description
0	OV0	RW1C	0	SS0 FIFO Overflow
Value Description				
		0		The FIFO has not overflowed.
		1		The FIFO for Sample Sequencer 0 has hit an overflow condition, meaning that the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped.
This bit is cleared by writing a 1.				

Register 6: ADC Event Multiplexer Select (ADCEMUX), offset 0x014

The **ADCEMUX** selects the event (trigger) that initiates sampling for each sample sequencer. Each sample sequencer can be configured with a unique trigger source.

ADC Event Multiplexer Select (ADCEMUX)

ADC0 base: 0x4003.8000

Register 8: ADC Trigger Source Select (ADCTSSEL), offset 0x01C

If a PWM Generator n is selected as a trigger source through the **EMn** bit field in the **ADC Event Multiplexer Select (ADCEMUX)** register, the **ADCTSSEL** register is programmed to identify in which PWM module instance the generator creating the trigger is located. The register resets to 0x0000.0000, which selects PWM module 0 for all generators. Note that field **PS3** selects the PWM module that maps to Generator 3; **PS2** selects the PWM module that maps to Generator 2, and so on.

The priorities assigned to the sequencers must be uniquely mapped. The ADC may not operate properly if two or more fields are equal.</p>

Register 10: ADC Sample Phase Control (ADCSPC), offset 0x024

The **ADC Sample Phase Control (ADCSPC)** register is used to insert a delay in ADC module sampling. This feature can be used with the SYNCWAIT and GSYNC bit in the **ADCPSSI** register to provide concurrent sampling of two different signals by two different ADC modules or skewed sampling of two ADC modules to increase the effective sampling rate. For concurrent sampling, the PHASE field of each ADC module must be the same and the sample and hold times (TSH_n) for the matching sample steps of each ADC must be the same. For example, both ADC0 and ADC1 would program PHASE = 0x0 in the **ADCSPC** register and might both have the following configuration for their **ADCSSTSH0** register:

- TSH7=0x4
- TSH6=0x2
- TSH5=0x2
- TSH4=0x8
- TSH3=0x6
- TSH2=0x2
- TSH1=0x4
- TSH0=0x2

For skewed sampling with a consistent phase lag, the TSH_n field in the **ADCSSTSHn** register must be the same for all sample steps of an ADC and for both ADC Modules. The desired lag can be calculated by adding the sample and hold time (TSH_n) to the twelve clock conversion time to determine the total number of clocks in a sample period. For example to create a 180.0° phase lag, the PHASE of the lagging ADC is calculated as:

$$\text{PHASE} = (\text{TSH}_n + 12)/2, \text{ where TSH}_n \text{ is in ADC_Clocks}$$

For situations where a predictable phase lag is not required, sample and hold times (TSH_n) of ADC modules can vary.

Note: Care should be taken when the PHASE field is non-zero, as the resulting delay in sampling the AIN_x input may result in undesirable system consequences. The time from ADC trigger to sample is increased and could make the response time longer than anticipated. The added latency could have ramifications in the system design. Designers should carefully consider the impact of this delay.

ADC Sample Phase Control (ADCSPC)

Register 11: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

This register also provides a means to configure and then initiate concurrent sampling on all ADC modules. To do this, the first ADC module should be configured. The **ADCPSSI** register for that module should then be written. The appropriate SS bits should be set along with the **SYNCWAIT** bit. Additional ADC modules should then be configured following the same procedure. Once the final ADC module is configured, its **ADCPSSI** register should be written with the appropriate SS bits set along with the **GSYNC** bit. All of the ADC modules then begin concurrent sampling according to their configuration.

ADC Processor Sample Sequence Initiate (ADCPSSI)

Register 12: ADC Sample Averaging Control (ADCSAC), offset 0x030

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from 2^{AVG} consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG=7 provides unpredictable results.

ADC Sample Averaging Control (ADCSAC)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x030

Register 15: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register, along with the **ADCSSEMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If the corresponding **EMUXn** bit in the **ADCSSEMUX0** register is set, the **MUXn** field in this register selects from **AIN[23:16]**. When the corresponding **EMUXn** bit is clear, the **MUXn** field selects from **AIN[15:0]**. This register is 32 bits wide and contains information for eight possible samples.

Note: Channels **AIN[31:24]** do not exist on this microcontroller. Configuring **MUXn** to be **0x8-0xF** when the corresponding **EMUXn** bit is set results in undefined behavior.

ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x040

Type RW, reset 0x0000.0000

Type	RW	RW	RW	RW												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:28	MUX7	RW	0x0	8th Sample Input Select The MUX7 field is used during the eighth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. The value set here indicates the corresponding pin, for example, a value of 0x1 when EMUX7 is clear indicates the input is AIN1 . A value of 0x1 when EMUX7 is set indicates the input is AIN17 . If differential sampling is enabled (the D7 bit in the ADCSSCTL0 register is set), this field must be set to the pair number "i", where the paired inputs are "2i and 2i+1".
27:24	MUX6	RW	0x0	7th Sample Input Select The MUX6 field is used during the seventh sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
23:20	MUX5	RW	0x0	6th Sample Input Select The MUX5 field is used during the sixth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
19:16	MUX4	RW	0x0	5th Sample Input Select The MUX4 field is used during the fifth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.

Bit/Field	Name	Type	Reset	Description
15:12	MUX3	RW	0x0	4th Sample Input Select The MUX3 field is used during the fourth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
11:8	MUX2	RW	0x0	3rd Sample Input Select The MUX2 field is used during the third sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
7:4	MUX1	RW	0x0	2nd Sample Input Select The MUX1 field is used during the second sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
3:0	MUX0	RW	0x0	1st Sample Input Select The MUX0 field is used during the first sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.

Register 16: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the `END` bit must be set for the final sample, whether it be after the first sample, eighth sample, or any sample in between. This register is 32 bits wide and contains information for eight possible samples.

ADC Sample Sequence Control 0 (ADCSSCTL0)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x044

Type RW, reset 0x0000.0000

Register 17: ADC Sample Sequence Result FIFO 0 (ADCSS FIFO0), offset 0x048**Register 18: ADC Sample Sequence Result FIFO 1 (ADCSS FIFO1), offset 0x068****Register 19: ADC Sample Sequence Result FIFO 2 (ADCSS FIFO2), offset 0x088****Register 20: ADC Sample Sequence Result FIFO 3 (ADCSS FIFO3), offset 0x0A8**

Important: This register is read-sensitive. See the register description for details.

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSS FIFO0** register is used for Sample Sequencer 0, **ADCSS FIFO1** for Sequencer 1, **ADCSS FIFO2** for Sequencer 2, and **ADCSS FIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCOSTAT** and **ADCUSTAT** registers.

ADC Sample Sequence Result FIFO n (ADCSS FIFO_n)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x048

Type RO, reset -

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	DATA	RO	-	Conversion Result Data

Register 21: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C

Register 22: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C

Register 23: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C

Register 24: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC

This register provides a window into the sample sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO with the head and tail pointers both pointing to index 0. The **ADCSSFSTAT0** register provides status on FIFO0, which has 8 entries; **ADCSSFSTAT1** on FIFO1, which has 4 entries; **ADCSSFSTAT2** on FIFO2, which has 4 entries; and **ADCSSFSTAT3** on FIFO3 which has a single entry.

Register 27: ADC Sample Sequence Extended Input Multiplexer Select 0 (ADCSSEMUX0), offset 0x058

This register, along with the **ADCSSMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If a bit in this register is set, the corresponding **MUXn** field in the **ADCSSMUX0** register selects from **AIN[23 : 16]**. When a bit in this register is clear, the corresponding **MUXn** field selects from **AIN[15 : 0]**. This register is 32 bits wide and contains information for eight possible samples.

Note that this register is not used when the differential channel designation is used (the **D_n** bit is set in the **ADCSSCTL0** register) because the **ADCSSMUX0** register can select all the available pairs.

ADC Sample Sequence Extended Input Multiplexer Select 0 (ADCSSEMUX0)

7:5	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	EMUX1	RW	0x0	2th Sample Input Select (Upper Bit) The EMUX1 field is used during the second sample of a sequence executed with the sample sequencer. This bit has the same description as EMUX7.
3:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	EMUX0	RW	0x0	1st Sample Input Select (Upper Bit) The EMUX0 field is used during the first sample of a sequence executed with the sample sequencer. This bit has the same description as EMUX7.

Register 28: ADC Sample Sequence 0 Sample and Hold Time (ADCSSTSH0), offset 0x05C

This register controls the sample period size for each sample of sequencer 0. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1204.

Note: If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks (TSHn = 0x4).

3:0	TSH0	RW	0x0	1st Sample and Hold Period Select The TSH0 field is used during the first sample of a sequence executed with the sample sequencer.

Register 29: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060

Register 30: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080

This register, along with the **ADCSSEMUX1** or **ADCSSEMUX2** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 1 or 2. If the corresponding **EMUXn** bit in the **ADCSSEMUX1** or **ADCSSEMUX2** register is set, the **MUXn** field in this register selects from **AIN[23 : 16]**. When the corresponding **EMUXn** bit is clear, the **MUXn** field selects from **AIN[15 : 0]**. These registers are 16 bits wide and contain information for four possible samples. See the **ADCSSMUX0** register on page 1255 for detailed bit descriptions. The **ADCSSMUX1** register affects Sample Sequencer 1 and the **ADCSSMUX2** register affects Sample Sequencer 2.

Note: Channels **AIN[31 : 24]** do not exist on this microcontroller. Configuring **MUXn** to be **0x8-0xF** when the corresponding **EMUXn** bit is set results in undefined behavior.

Register 31: ADC Sample Sequence Control 1 (ADCSSCTL1), offset 0x064**Register 32: ADC Sample Sequence Control 2 (ADCSSCTL2), offset 0x084**

These registers contain the configuration information for each sample for a sequence executed with Sample Sequencer 1 or 2. When configuring a sample sequence, the END bit must be set for the final sample, whether it be after the first sample, fourth sample, or any sample in between. These registers are 16-bits wide and contain information for four possible samples. See the **ADCSSCTL0** register on page 1257 for detailed bit descriptions. The **ADCSSCTL1** register configures Sample Sequencer 1 and the **ADCSSCTL2** register configures Sample Sequencer 2.

15 TS3 RW 0 4th Sample Temp Sensor Select

Value	Description
0	The input pin specified by the ADCSSMUXn register is read during the fourth sample of the sample sequence.
1	The temperature sensor is read during the fourth sample of the sample sequence.

14 IE3 RW 0 4th Sample Interrupt Enable

Value	Description
0	The raw interrupt is not asserted to the interrupt controller.
1	The raw interrupt signal (INR0 bit) is asserted at the end of the fourth sample's conversion. If the MASK0 bit in the ADCIM register is set, the interrupt is promoted to the interrupt controller.

It is legal to have multiple samples within a sequence generate interrupts.

Register 35: ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1), offset 0x074

Register 36: ADC Sample Sequence 2 Digital Comparator Select (ADCSSDC2), offset 0x094

These registers determine which digital comparator receives the sample from the given conversion on Sample Sequence n if the corresponding $S_{n}DCOP$ bit in the **ADCSSOPn** register is set. The **ADCSSDC1** register controls the selection for Sample Sequencer 1 and the **ADCSSDC2** register controls the selection for Sample Sequencer 2.

11:8 S2DCSEL RW 0x0 Sample 2 Digital Comparator Select
This field has the same encodings as S3DCSEL but is used during the third sample.

Bit/Field	Name	Type	Reset	Description
7:4	S1DCSEL	RW	0x0	Sample 1 Digital Comparator Select This field has the same encodings as S3DCSEL but is used during the second sample.
3:0	S0DCSEL	RW	0x0	Sample 0 Digital Comparator Select This field has the same encodings as S3DCSEL but is used during the first sample.

Register 37: ADC Sample Sequence Extended Input Multiplexer Select 1 (ADCSSEMUX1), offset 0x078

Register 38: ADC Sample Sequence Extended Input Multiplexer Select 2 (ADCSSEMUX2), offset 0x098

This register, along with the **ADCSSMUX1** or **ADCSSMUX2** register, defines the analog input configuration for each sample in a sequence executed with either Sample Sequencer 1 or 2. If a bit in this register is set, the corresponding **MUXn** field in the **ADCSSMUX1** or **ADCSSMUX2** register selects from **AIN[23 : 16]**. When a bit in this register is clear, the corresponding **MUXn** field selects from **AIN[15 : 0]**. This register is 16 bits wide and contains information for four possible samples. The **ADCSSEMUX1** register controls Sample Sequencer 1 and the **ADCSSEMUX2** register controls Sample Sequencer 2.

Note that this register is not used when the differential channel designation is used (the **D_n** bit is set in the **ADCSSCTL1** or **ADCSSCTL2** register) because the **ADCSSMUX1** or **ADCSSMUX2** register can select all the available pairs.

Register 39: ADC Sample Sequence 1 Sample and Hold Time (ADCSSTSH1), offset 0x07C

Register 40: ADC Sample Sequence 2 Sample and Hold Time (ADCSSTSH2), offset 0x09C

These registers control the sample period size for each sample step of sequencer 1 and sequencer 2. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1204.

Note: If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks ($TSHn = 0x4$).

Register 41: ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3), offset 0x0A0

This register, along with the **ADCSSEMUX3** register, defines the analog input configuration for the sample in a sequence executed with Sample Sequencer 3. If the EMUX0 bit in the **ADCSSEMUX3** register is set, the MUX0 field in this register selects from AIN[23 : 16]. When the EMUX0 bit is clear, the MUX0 field selects from AIN[15 : 0]. This register is four bits wide and contains information for one possible sample. See the **ADCSSMUX0** register on page 1255 for detailed bit descriptions.

Register 42: ADC Sample Sequence Control 3 (ADCSSCTL3), offset 0x0A4

This register contains the configuration information for a sample executed with Sample Sequencer 3. This register is 4 bits wide and contains information for one possible sample. See the **ADCSSCTL0** register on page 1257 for detailed bit descriptions.

Note: When configuring a sample sequence in this register, the END0 bit must be set.

ADC Sample Sequence Control 3 (ADCSSCTL3)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0xA4

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TS0	RW	0	1st Sample Temp Sensor Select Value Description 0 The input pin specified by the ADCSSMUXn register is read during the first sample of the sample sequence. 1 The temperature sensor is read during the first sample of the sample sequence.
2	IE0	RW	0	Sample Interrupt Enable Value Description 0 The raw interrupt is not asserted to the interrupt controller. 1 The raw interrupt signal (INR0 bit) is asserted at the end of this sample's conversion. If the MASK0 bit in the ADCIM register is set, the interrupt is promoted to the interrupt controller. It is legal to have multiple samples within a sequence generate interrupts.
1	END0	RW	0	End of Sequence This bit must be set before initiating a single sample sequence. Value Description 0 Sampling and conversion continues. 1 This is the end of sequence.

Bit/Field	Name	Type	Reset	Description
0	D0	RW	0	Sample Differential Input Select
Value Description				
		0		The analog inputs are not differentially sampled.
		1		The analog input is differentially sampled. The corresponding ADCSSMUXn nibble must be set to the pair number "i", where the paired inputs are "2i and 2i+1".
Because the temperature sensor does not have a differential option, this bit must not be set when the TS0 bit is set.				

Register 43: ADC Sample Sequence 3 Operation (ADCSSOP3), offset 0x0B0

This register determines whether the sample from the given conversion on Sample Sequence 3 is saved in the Sample Sequence 3 FIFO or sent to the digital comparator unit.

Register 47: ADC Digital Comparator Reset Initial Conditions (ADCDCRIC), offset 0xD00

This register provides the ability to reset any of the digital comparator interrupt or trigger functions back to their initial conditions. Resetting these functions ensures that the data that is being used by the interrupt and trigger functions in the digital comparator unit is not stale.

ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)

ADC0 base: 0x4003.8000

23 DCTRIG7 WO 0 Digital Comparator Trigger 7

Value Description

0 No effect.

1 Resets the Digital Comparator 7 trigger unit to its initial conditions.

When the trigger has been cleared, this bit is automatically cleared.

Because the digital comparators use the current and previous ADC conversion values to determine when to assert the trigger, it is important to reset the digital comparator to initial conditions when starting a new sequence so that stale data is not used. After setting this bit, software should wait until the bit clears before continuing.

22 DCTRIG6 WO 0 Digital Comparator Trigger 6

Value Description

0 No effect.

1 Resets the Digital Comparator 6 trigger unit to its initial conditions.

When the trigger has been cleared, this bit is automatically cleared.

Because the digital comparators use the current and previous ADC conversion values to determine when to assert the trigger, it is important to reset the digital comparator to initial conditions when starting a new sequence so that stale data is not used.

19 Universal Asynchronous Receivers/Transmitters (UARTs)

The TM4C129XKCZAD controller includes eight Universal Asynchronous Receiver/Transmitter (UART) with the following features:

- Programmable baud-rate generator allowing speeds up to 7.5 Mbps for regular speed (divide by 16) and 15 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
 - 5, 6, 7, or 8 data bits
 - Even, odd, stick, or no-parity bit generation/detection
 - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
 - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
 - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
 - Support of normal 3/16 and low-power (1.41-2.23 µs) bit durations
 - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem functionality available on the following UARTs:
 - UART0 (modem flow control and modem status)
 - UART1 (modem flow control and modem status)
 - UART2 (modem flow control)
 - UART3 (modem flow control)
 - UART4 (modem flow control)
- EIA-485 9-bit support

- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive
 - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
 - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock

19.1 Block Diagram

Figure 19-1. UART Module Block Diagram

19.2 Signal Description

The following table lists the external signals of the UART module and describes the function of each. The UART signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Assignment" lists the possible GPIO pin

placements for these UART signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the UART function. The number in parentheses is the encoding that must be programmed into the PMC_n field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the UART signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 769.

19.3 Functional Description

Each TM4C129XKCZAD UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 1335). Transmit and receive are both enabled out of reset. Before any

control registers are programmed, the UART must be disabled by clearing the **UARTEN** bit in **UARTCTL**. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the **UARTCTL** register.

19.3.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 19-2 on page 1311 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

Figure 19-2. UART Character Frame

19.3.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divisor allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 1331) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 1332). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$\text{BRD} = \text{BRDI} + \text{BRDF} = \text{UARTSysClk} / (\text{ClkDiv} * \text{Baud Rate})$$

where **UARTSysClk** is the system clock connected to the UART, and **ClkDiv** is either 16 (if **HSE** in **UARTCTL** is clear) or 8 (if **HSE** is set). By default, this will be the main system clock described in “Clock Control” on page 240. Alternatively, the UART may be clocked from the internal precision oscillator (PIOSC), independent of the system clock selection. This will allow the UART clock to be programmed independently of the system clock PLL settings. See the **UARTCC** register for more details.

The 6-bit fractional number (that is to be loaded into the **DIVFRAC** bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8x or 16x the baud-rate (referred to as **Baud8** and **Baud16**, depending on the setting of the **HSE** bit (bit 5) in **UARTCTL**). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during

receive operations. Note that the state of the `HSE` bit has no effect on clock generation in ISO 7816 smart card mode (when the `SMART` bit in the `UARTCTL` register is set).

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 1333), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated when a write operation to `UARTLCRH` is performed, so any changes to the baud-rate divisor must be followed by a write to the `UARTLCRH` register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- **UARTIBRD** write, **UARTFBRD** write, and **UARTLCRH** write
- **UARTFBRD** write, **UARTIBRD** write, and **UARTLCRH** write
- **UARTIBRD** write and **UARTLCRH** write
- **UARTFBRD** write and **UARTLCRH** write

19.3.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit FIFO. The `BUSY` bit in the **UART Flag (UARTFR)** register (see page 1327) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The `BUSY` bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the `UnRx` signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of Baud16 or fourth cycle of Baud8 depending on the setting of the `HSE` bit (bit 5) in **UARTCTL** (described in “Transmit/Receive Logic” on page 1311).

The start bit is valid and recognized if the `UnRx` signal is still low on the eighth cycle of Baud16 (`HSE` clear) or the fourth cycle of Baud 8 (`HSE` set), otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of Baud16 or 8th cycle of Baud8 (that is, one bit period later) according to the programmed length of the data characters and value of the `HSE` bit in **UARTCTL**. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if the `UnRx` signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

19.3.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the `UnTx` and `UnRx` pins for the SIR protocol. These signals should be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before

data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of $3/16$ th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW and driving the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal ($1.63 \mu s$, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCTL** register (see page 1335).

Whether the device is in normal or low-power IrDA mode, a start bit is deemed valid if the decoder is still Low, one period of IrLPBaud16 after the Low was first detected. This enables a normal-mode UART to receive data from a low-power mode UART that can transmit pulses as small as $1.41 \mu s$. Thus, for both low-power and normal mode operation, the **ILPDVSR** field in the **UARTILPR** register must be programmed such that $1.42 \text{ MHz} < F_{\text{IrLPBaud16}} < 2.12 \text{ MHz}$, resulting in a low-power pulse duration of $1.41\text{--}2.11 \mu s$ (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than $1.4 \mu s$ are accepted as valid pulses.

Figure 19-3 on page 1313 shows the UART transmit and receive signals, with and without IrDA modulation.

Figure 19-3. IrDA Data Modulation

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10-ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

19.3.5 ISO 7816 Support

The UART offers basic support to allow communication with an ISO 7816 smartcard. When bit 3 (SMART) of the **UARTCTL** register is set, the **UnTx** signal is used as a bit clock, and the **UnRx** signal is used as the half-duplex communication line connected to the smartcard. A GPIO signal can be used to generate the reset signal to the smartcard. The remaining smartcard signals should be provided by the system design. The maximum clock rate in this mode is system clock / 16.

When using ISO 7816 mode, the **UARTLCRH** register must be set to transmit 8-bit words (**WLEN** bits 6:5 configured to 0x3) with EVEN parity (**PEN** set and **EPS** set). In this mode, the UART automatically uses 2 stop bits, and the **STP2** bit of the **UARTLCRH** register is ignored.

If a parity error is detected during transmission, **UnRx** is pulled Low during the second stop bit. In this case, the UART aborts the transmission, flushes the transmit FIFO and discards any data it contains, and raises a parity error interrupt, allowing software to detect the problem and initiate retransmission of the affected data. Note that the UART does not support automatic retransmission in this case.

19.3.6 Modem Handshake Support

This section describes how to configure and use the modem flow control and status signals for a UART when connected as a DTE (data terminal equipment) or as a DCE (data communications equipment). In general, a modem is a DCE and a computing device that connects to a modem is the DTE.

19.3.6.1 Signaling

The status signals provided by a UART differ based on whether the UART is used as a DTE or DCE. When used as a DTE, the modem flow control and status signals are defined as:

- **UnCTS** is Clear To Send
- **UnDSR** is Data Set Ready
- **UnDCD** is Data Carrier Detect
- **UnRTI** is Ring Indicator
- **UnRTS** is Request To Send
- **UnDTR** is Data Terminal Ready

When used as a DCE, the modem flow control and status signals are defined as:

- **UnCTS** is Request To Send
- **UnDSR** is Data Terminal Ready
- **UnRTS** is Clear To Send
- **UnDTR** is Data Set Ready

Note that the support for DCE functions Data Carrier Detect and Ring Indicator are not provided. If these signals are required, their function can be emulated by using a general-purpose I/O signal and providing software support.

19.3.6.2 Flow Control

Flow control can be accomplished by either hardware or software. The following sections describe the different methods.

Hardware Flow Control (RTS/CTS)

Hardware flow control between two devices is accomplished by connecting the $\overline{\text{UnRTS}}$ output to the Clear-To-Send input on the receiving device, and connecting the Request-To-Send output on the receiving device to the $\overline{\text{UnCTS}}$ input.

The $\overline{\text{UnCTS}}$ input controls the transmitter. The transmitter may only transmit data when the $\overline{\text{UnCTS}}$ input is asserted. The $\overline{\text{UnRTS}}$ output signal indicates the state of the receive FIFO. $\overline{\text{UnCTS}}$ remains asserted until the preprogrammed watermark level is reached, indicating that the Receive FIFO has no space to store additional characters.

The **UARTCTL** register bits 15 (CTSEN) and 14 (RTSEN) specify the flow control mode as shown in Table 19-2 on page 1315.

Table 19-2. Flow Control Mode

CTSEN	RTSEN	Description
1	1	RTS and CTS flow control enabled
1	0	Only CTS flow control enabled
0	1	Only RTS flow control enabled
0	0	Both RTS and CTS flow control disabled

Note that when RTSEN is 1, software cannot modify the $\overline{\text{UnRTS}}$ output value through the **UARTCTL** register Request to Send (RTS) bit, and the status of the RTS bit should be ignored.

Software Flow Control (Modem Status Interrupts)

Software flow control between two devices is accomplished by using interrupts to indicate the status of the UART. Interrupts may be generated for the $\overline{\text{UnDSR}}$, $\overline{\text{UnDCD}}$, $\overline{\text{UnCTS}}$, and $\overline{\text{UnRTI}}$ signals using bits 3:0 of the **UARTIM** register, respectively. The raw and masked interrupt status may be checked using the **UARTRIS** and **UARTMIS** register. These interrupts may be cleared using the **UARTICR** register.

19.3.7 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the **9BITEN** bit in the **UART9BITADDR** register. This feature is useful in a multi-drop configuration of the UART where a single master connected to multiple slaves can communicate with a particular slave through its address or set of addresses along with a qualifier for an address byte. All the slaves check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then it receives or sends further data. If the address does not match, it drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and it can be configured with the **UART9BITADDR** register. The matching can be extended to a set of addresses using the address mask in the **UART9BITAMASK** register. By default, the **UART9BITAMASK** is 0xFF, meaning that only the specified address is matched.

When not finding a match, the rest of the data bytes with the 9th bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared 9th bit are stored in the FIFO. Software can mask this interrupt in case μ DMA and/or FIFO operations are enabled for this instance and processor intervention is not required. All the

send transactions with 9-bit mode are data bytes and the 9th bit is cleared. Software can override the 9th bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The Transmit FIFO does not hold the address/data bit, hence software should take care of enabling the address bit appropriately.

19.3.8 FIFO Operation

The UART has two 16x8 FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 1322). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the **FEN** bit in **UARTLCRH** (page 1333).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 1327) and the **UART Receive Status (UARTRSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits), and the **UARTRSR** register shows overrun status via the **OE** bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 1339). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and $\frac{7}{8}$. For example, if the $\frac{1}{4}$ option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the $\frac{1}{2}$ mark.

19.3.9 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the TXIFLSEL bit in the **UARTIFLS** register is met, or if the **EOT** bit in **UARTCTL** is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the RXIFLSEL bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 1349).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 1341) by setting the corresponding **IM** bits. If interrupts are not used, the raw interrupt status is always visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 1345).

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by writing a 1 to the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 1353).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period when the **HSE** bit is clear or over a 64-bit period when the **HSE** bit is set. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the **RXRIS** bit is set. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, or by clearing the interrupt by writing a 1 to the **RXIC** bit.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the **RXRIS** bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt by writing a 1 to the **RXIC** bit.

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the **TXRIS** bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, or by clearing the interrupt by writing a 1 to the **TXIC** bit.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the **TXRIS** bit is set. It is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by writing a 1 to the **TXIC** bit.

19.3.10 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the **LBE** bit in the **UARTCTL** register (see page 1335). In loopback mode, data transmitted on the **UnTx** output is received on the **UnRx** input. Note that the **LBE** bit should be set before the UART is enabled.

19.3.11 DMA Operation

The UART provides an interface to the μDMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the **UARTIFLS** register. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the μDMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, set the **RXDMAE** bit of the **DMA Control (UARTDMACTL)** register. To enable DMA operation for the transmit channel, set the **TXDMAE** bit of the **UARTDMACTL** register. The UART can also be configured to stop using DMA for the receive

channel if a receive error occurs. If the **DMAERR** bit of the **UARTDMACR** register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

When the µDMA is finished transferring data to the TX FIFO or from the RX FIFO, a **dma_done** signal is sent to the UART to indicate completion. The **dma_done** status is indicated through the **DMATXRIS** and **DMARXIS** bits of the **UARTRIS** register. An interrupt can be generated from these status bits by setting the **DMATXIM** and/or **DMARXIM** bits in the **UARTIM** register.

Note: The **DMATXRIS** bit can be used to indicate the µDMA's completion of data transfer to the TX FIFO. To indicate transfer completion from the UART's serializer, the end-of-transmission bit (**EOT** bit) should be enabled in the **UARTCTL** register. An interrupt can be generated on an end-of-transmission completion by setting the **EOTIM** bit of the **UARTIM** register.

See “Micro Direct Memory Access (µDMA)” on page 705 for more details about programming the µDMA controller.

19.4 Initialization and Configuration

To enable and initialize the UART, the following steps are necessary:

1. Enable the UART module using the **RCGCUART** register (see page 404).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 398). To find out which GPIO port to enable, refer to Table 31-5 on page 2085.
3. Set the GPIO **AFSEL** bits for the appropriate pins (see page 799). To determine which GPIOs to configure, see Table 31-4 on page 2068.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected (see page 801 and page 809).
5. Configure the **PMCl_n** fields in the **GPIOPCTL** register to assign the UART signals to the appropriate pins (see page 816 and Table 31-5 on page 2085).

To use the UART, the peripheral clock must be enabled by setting the appropriate bit in the **RCGCUART** register (page 404). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (page 398) in the System Control module. To find out which GPIO port to enable, refer to Table 31-5 on page 2085.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz, and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled
- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), because the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in “Baud-Rate Generation” on page 1311, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the DIVINT field of the **UARTIBRD** register (see page 1331) should be set to 10 decimal or 0xA. The value to be loaded into the **UARTFBRD** register (see page 1332) is calculated by the equation:

$$\text{UARTFBRD [DIVFRAC]} = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the **UARTEN** bit in the **UARTCTL** register.
2. Write the integer portion of the BRD to the **UARTIBRD** register.
3. Write the fractional portion of the BRD to the **UARTFBRD** register.
4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Configure the UART clock source by writing to the **UARTCC** register.
6. Optionally, configure the µDMA channel (see “Micro Direct Memory Access (µDMA)” on page 705) and enable the DMA option(s) in the **UARTDMACTL** register.
7. Enable the UART by setting the **UARTEN** bit in the **UARTCTL** register.

19.5 Register Map

Table 19-3 on page 1320 lists the UART registers. The offset listed is a hexadecimal increment to the register's address, relative to that UART's base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000
- UART2: 0x4000.E000
- UART3: 0x4000.F000
- UART4: 0x4001.0000
- UART5: 0x4001.1000
- UART6: 0x4001.2000
- UART7: 0x4001.3000

The UART module clock must be enabled before the registers can be programmed (see page 404). There must be a delay of 3 system clocks after the UART module clock is enabled before any UART module registers are accessed.

The UART must be disabled (see the **UARTEN** bit in the **UARTCTL** register on page 1335) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

Note: Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)

- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

19.6 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

Register 1: UART Data (UARTDR), offset 0x000

Important: This register is read-sensitive. See the register description for details.

This register is the data register (the interface to the FIFOs).

For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

UART Data (UARTDR)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

UART3 base: 0x4000.F000

UART4 base: 0x4001.0000

UART5 base: 0x4001.1000

UART6 base: 0x4001.2000

UART7 base: 0x4001.3000

Offset 0x000

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	OE	RO	0	UART Overrun Error
		Value	Description	
		0	No data has been lost due to a FIFO overrun.	
		1	New data was received when the FIFO was full, resulting in data loss.	

Bit/Field	Name	Type	Reset	Description						
10	BE	RO	0	<p>UART Break Error</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No break condition has occurred</td></tr> <tr> <td>1</td><td>A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).</td></tr> </tbody> </table> <p>In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the received data input goes to a 1 (marking state), and the next valid start bit is received.</p>	Value	Description	0	No break condition has occurred	1	A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).
Value	Description									
0	No break condition has occurred									
1	A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).									
9	PE	RO	0	<p>UART Parity Error</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No parity error has occurred</td></tr> <tr> <td>1</td><td>The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.</td></tr> </tbody> </table> <p>In FIFO mode, this error is associated with the character at the top of the FIFO.</p>	Value	Description	0	No parity error has occurred	1	The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.
Value	Description									
0	No parity error has occurred									
1	The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.									
8	FE	RO	0	<p>UART Framing Error</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No framing error has occurred</td></tr> <tr> <td>1</td><td>The received character does not have a valid stop bit (a valid stop bit is 1).</td></tr> </tbody> </table>	Value	Description	0	No framing error has occurred	1	The received character does not have a valid stop bit (a valid stop bit is 1).
Value	Description									
0	No framing error has occurred									
1	The received character does not have a valid stop bit (a valid stop bit is 1).									
7:0	DATA	RW	0x00	<p>Data Transmitted or Received</p> <p>Data that is to be transmitted via the UART is written to this field. When read, this field contains the data that was received by the UART.</p>						

Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared on reset.

Read-Only Status Register

UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

UART3 base: 0x4000.F000

UART4 base: 0x4001.0000

UART5 base: 0x4001.1000

UART6 base: 0x4001.2000

UART7 base: 0x4001.3000

Offset 0x004

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

3	OE	RO	0	UART Overrun Error
---	----	----	---	--------------------

Value	Description
0	No data has been lost due to a FIFO overrun.
1	New data was received when the FIFO was full, resulting in data loss.

This bit is cleared by a write to **UARTECR**.

The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO.

Bit/Field	Name	Type	Reset	Description						
2	BE	RO	0	<p>UART Break Error</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No break condition has occurred</td></tr> <tr> <td>1</td><td>A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).</td></tr> </tbody> </table> <p>This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.</p>	Value	Description	0	No break condition has occurred	1	A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).
Value	Description									
0	No break condition has occurred									
1	A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).									
1	PE	RO	0	<p>UART Parity Error</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No parity error has occurred</td></tr> <tr> <td>1</td><td>The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.</td></tr> </tbody> </table> <p>This bit is cleared to 0 by a write to UARTECR.</p>	Value	Description	0	No parity error has occurred	1	The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.
Value	Description									
0	No parity error has occurred									
1	The parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.									
0	FE	RO	0	<p>UART Framing Error</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No framing error has occurred</td></tr> <tr> <td>1</td><td>The received character does not have a valid stop bit (a valid stop bit is 1).</td></tr> </tbody> </table> <p>This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO.</p>	Value	Description	0	No framing error has occurred	1	The received character does not have a valid stop bit (a valid stop bit is 1).
Value	Description									
0	No framing error has occurred									
1	The received character does not have a valid stop bit (a valid stop bit is 1).									

Write-Only Error Clear Register

UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

UART3 base: 0x4000.F000

UART4 base: 0x4001.0000

UART5 base: 0x4001.1000

UART6 base: 0x4001.2000

UART7 base: 0x4001.3000

Offset 0x004

Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	WO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	WO	0x00	Error Clear A write to this register of any data clears the framing, parity, break, and overrun flags.

Register 3: UART Flag (UARTFR), offset 0x018

The **UARTFR** register is the flag register. After reset, the TXFF, RXFF, and BUSY bits are 0, and TXFE and RXFE bits are 1.

Note: Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

UART Flag (UARTFR)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

UART3 base: 0x4000.F000

UART4 base: 0x4001.0000

UART5 base: 0x4001.1000

UART6 base: 0x4001.2000

UART7 base: 0x4001.3000

Offset 0x018

Type RO, reset 0x0000.0090

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	RI	RO	0	Ring Indicator
	Value	Description		
	0	The UnRI signal is not asserted.		
	1	The UnRI signal is asserted.		

Bit/Field	Name	Type	Reset	Description						
7	TXFE	RO	1	<p>UART Transmit FIFO Empty</p> <p>The meaning of this bit depends on the state of the FEN bit in the UARTLCRH register.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The transmitter has data to transmit.</td></tr> <tr> <td>1</td><td>If the FIFO is disabled (FEN is 0), the transmit holding register is empty. Value	Description									
0	The U1CTS signal is not asserted.									
1	The UnCTS signal is asserted.									

Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset.

The internal IrLPBaud16 clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the IrLPBaud16 clock. The low-power divisor value is calculated as follows:

$$\text{ILPDVSR} = \text{SysClk} / F_{\text{IrLPBaud16}}$$

where $F_{\text{IrLPBaud16}}$ is nominally 1.8432 MHz.

Because the IrLPBaud16 clock is used to sample transmitted data irrespective of mode, the ILPDVSR field must be programmed in both low power and normal mode, such that $1.42 \text{ MHz} < F_{\text{IrLPBaud16}} < 2.12 \text{ MHz}$, resulting in a low-power pulse duration of 1.41–2.11 μs (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4 μs are accepted as valid pulses.

Note: Zero is an illegal value. Programming a zero value results in no IrLPBaud16 pulses being generated.

UART IrDA Low-Power Register (UARTILPR)

7:0	ILPDVSR	RW	0x00	IrDA Low-Power Divisor This field contains the 8-bit low-power divisor value.

Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 1311 for configuration details.

Register 6: UART Fractional Baud-Rate Divisor (UARTFBRD), offset 0x028

The **UARTFBRD** register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the **UARTFBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 1311 for configuration details.

5:0	DIVFRAC	RW	0x0	Fractional Baud-Rate Divisor

Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

UART Line Control (UARTLCRH)

UART0 base: 0x4000.C000

UART6 base: 0x4001.2000

UART7 base: 0x4001.3000

Offset 0x02C

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	SPS	RW	0	UART Stick Parity Select When bits 1, 2, and 7 of UARTLCRH are set, the parity bit is transmitted and checked as a 0. When bits 1 and 7 are set and 2 is cleared, the parity bit is transmitted and checked as a 1. When this bit is cleared, stick parity is disabled.
6:5	WLEN	RW	0x0	UART Word Length The bits indicate the number of data bits transmitted or received in a frame as follows: Value Description 0x0 5 bits (default) 0x1 6 bits 0x2 7 bits 0x3 8 bits

Bit/Field	Name	Type	Reset	Description
4	FEN	RW	0	UART Enable FIFOs Value Description 0 The FIFOs are disabled (Character mode). The FIFOs become 1-byte-deep holding registers. 1 The transmit and receive FIFO buffers are enabled (FIFO mode).
3	STP2	RW	0	UART Two Stop Bits Select Value Description 0 One stop bit is transmitted at the end of a frame. 1 Two stop bits are transmitted at the end of a frame. The receive logic does not check for two stop bits being received. When in 7816 smartcard mode (the SMART bit is set in the UARTCTL register), the number of stop bits is forced to 2.
2	EPS	RW	0	UART Even Parity Select Value Description 0 Odd parity is performed, which checks for an odd number of 1s. 1 Even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits. This bit has no effect when parity is disabled by the PEN bit.
1	PEN	RW	0	UART Parity Enable Value Description 0 Parity is disabled and no parity bit is added to the data frame. 1 Parity checking and generation is enabled.
0	BRK	RW	0	UART Send Break Value Description 0 Normal use. 1 A Low level is continually output on the UnTx signal, after completing transmission of the current character. For the proper execution of the break command, software must set this bit for at least two frames (character periods).

Register 8: UART Control (UARTCTL), offset 0x030

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set.

To enable the UART module, the **UARTEN** bit must be set. If software requires a configuration change in the module, the **UARTEN** bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

Note: Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

Note: The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by clearing bit 4 (FEN) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the TXRIS and RXRIS bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

UART Interrupt FIFO Level Select (UARTIFLS)

Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

Note: Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

0	RIIM	RW	0	UART Ring Indicator Modem Interrupt Mask
				Value Description
			0	The RIRIS interrupt is suppressed and not sent to the interrupt controller.
			1	An interrupt is sent to the interrupt controller when the RIRIS bit in the UARTRIS register is set.

Register 11: UART Raw Interrupt Status (UARTRIS), offset 0x03C

The **UARTRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt. A write has no effect.

UART Raw Interrupt Status (UARTRIS)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

UART3 base: 0x4000.F000

0	RIMIS	RO	0	UART Ring Indicator Modem Masked Interrupt Status Value Description 0 An interrupt has not occurred or is masked. 1 An unmasked interrupt was signaled due to Ring Indicator. This bit is cleared by writing a 1 to the RIIC bit in the UARTICR register.

Register 13: UART Interrupt Clear (UARTICR), offset 0x044

The **UARTICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

Note that bits [3:0] are only implemented on UART1. These bits are reserved on UART0 and UART2.

7:0	MASK	RW	0xFF	Self Address Mask for 9-Bit Mode This field contains the address mask that creates a set of addresses that should be matched.

Register 17: UART Peripheral Properties (UARTPP), offset 0xFC0

The **UARTPP** register provides information regarding the properties of the UART module.

UART Peripheral Properties (UARTPP)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

UART3 base: 0x4000.F000

UART4 base: 0x4001.0000

UART5 base: 0x4001.1000

UART6 base: 0x4001.2000

UART7 base: 0x4001.3000

Offset 0xFC0

Type RO, reset 0x0000.000F

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	MSE	RO	0x1	Modem Support Extended
	Value	Description		
	0	The UART module does not provide extended support for modem control.		
	1	The UART module provides extended support for modem control including <code>UARTnDTR</code> , <code>UARTnDSR</code> , <code>UARTnDCD</code> , and <code>UARTnRI</code> .		
2	MS	RO	0x1	Modem Support
	Value	Description		
	0	The UART module does not provide support for modem control.		
	1	The UART module provides support for modem control including <code>UARTnRTS</code> and <code>UARTnCTS</code> .		
1	NB	RO	0x1	9-Bit Support
	Value	Description		
	0	The UART module does not provide support for the transmission of 9-bit data for RS-485 support.		
	1	The UART module provides support for the transmission of 9-bit data for RS-485 support.		

Bit/Field	Name	Type	Reset	Description
0	SC	RO	0x1	Smart Card Support
				Value Description
			0	The UART module does not provide smart card support.
			1	The UART module provides smart card support.

Register 18: UART Clock Configuration (UARTCC), offset 0xFC8

The **UARTCC** register controls the baud clock source for the UART module. For more information, see the section called “Peripheral Clock Sources” on page 244.

Note: If the PIOSC is used for the UART baud clock, the system clock frequency must be at least 9 MHz in Run mode.

UART Clock Configuration (UARTCC)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

UART3 base: 0x4000.F000

UART4 base: 0x4001.0000

UART5 base: 0x4001.1000

UART6 base: 0x4001.2000

UART7 base: 0x4001.3000

Offset 0xFC8

Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:4 reserved RO 0x0000.0000 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

3:0 CS RW 0 UART Baud Clock Source

The following table specifies the source that generates for the UART baud clock:

Value	Description
0x0	System clock (based on clock source and divisor factor programmed in RSCLKCFG register in the System Control Module)
0x1-0x4	reserved
0x5	Alternate clock source as defined by ALTCLKCFG register in System Control Module.
0x5-0xF	Reserved

Register 19: UART Peripheral Identification 4 (UARTPeriphID4), offset 0xFD0

The **UARTPeriphIDn** registers are hard-coded and the fields within the registers determine the reset values.

UART Peripheral Identification 4 (UARTPeriphID4)

UART0 base: 0x4000.C000

UART1 base: 0x4000.D000

UART2 base: 0x4000.E000

UART3 base: 0x4000.F000

UART4 base: 0x4001.0000

UART5 base: 0x4001.1000

20 Quad Synchronous Serial Interface (QSSI)

The TM4C129XKCZAD microcontroller includes four Quad-Synchronous Serial Interface (QSSI) modules. All four of the modules support Advanced and Bi-SSI interfaces as well as a Quad-SSI enhancement to provide faster throughput of data. The QSSI module acts as a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, or Texas Instruments synchronous serial interfaces. The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The transmit and receive paths are buffered with internal, independent FIFO memories allowing up to eight 16-bit values in Legacy mode and 8-bit values in Advanced, Bi-, and Quad-modes. The CPU can access data in these FIFOs as well as the QSSI's control and status information. A μDMA interface is also provided to allow the transmit and receive FIFOs to be programmed as source/destination addresses in the μDMA module.

The TM4C129XKCZAD QSSI modules have the following features:

- Four QSSI channels with Advanced, Bi- and Quad-SSI functionality
- Programmable interface operation for Freescale SPI or Texas Instruments synchronous serial interfaces in Legacy Mode. Support for Freescale interface in Bi- and Quad-SSI mode.
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
 - Separate channels for transmit and receive
 - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
 - Transmit single request asserted when there is space in the FIFO; burst request asserted when four or more entries are available to be written in the FIFO
 - Maskable μDMA interrupts for receive and transmit complete
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock.

20.1 Block Diagram

The following figure below shows a block diagram of an QSSI module with Advanced, Bi- and Quad-SSI.

Figure 20-1. QSSI Module with Advanced, Bi-SSI and Quad-SSI Support

20.2 Signal Description

The following table lists the external signals of the QSSI module and describes the function of each. The QSSI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The "Pin Mux/Pin Assignment" column in the following table lists the possible GPIO pin placements for the QSSI signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the QSSI function. The number in

parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the QSSI signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 769. Note that for the QSSI module, when operating in Legacy Mode, `SSIInXDAT0` functions as `SSIInTX` and `SSIInXDAT1` functions as `SSIInRX`.

Table 20-1. SSI Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
SSI0Clk	T6	PA2 (15)	I/O	TTL	SSI module 0 clock
SSI0Fss	U5	PA3 (15)	I/O	TTL	SSI module 0 frame signal
SSI0XDAT0	V4	PA4 (15)	I/O	TTL	SSI Module 0 Bi-directional Data Pin 0 (SSI0TX in Legacy SSI Mode).
SSI0XDAT1	W4	PA5 (15)	I/O	TTL	SSI Module 0 Bi-directional Data Pin 1 (SSI0RX in Legacy SSI Mode).
SSI0XDAT2	V5	PA6 (13)	I/O	TTL	SSI Module 0 Bi-directional Data Pin 2.
SSI0XDAT3	R7	PA7 (13)	I/O	TTL	SSI Module 0 Bi-directional Data Pin 3.
SSI1Clk	B6	PB5 (15)	I/O	TTL	SSI module 1 clock.
SSI1Fss	C6	PB4 (15)	I/O	TTL	SSI module 1 frame signal.
SSI1XDAT0	A5	PE4 (15)	I/O	TTL	SSI Module 1 Bi-directional Data Pin 0 (SSI1TX in Legacy SSI Mode).
SSI1XDAT1	B5	PE5 (15)	I/O	TTL	SSI Module 1 Bi-directional Data Pin 1 (SSI1RX in Legacy SSI Mode).
SSI1XDAT2	A4	PD4 (15)	I/O	TTL	SSI Module 1 Bi-directional Data Pin 2.
SSI1XDAT3	B4	PD5 (15)	I/O	TTL	SSI Module 1 Bi-directional Data Pin 3.
SSI2Clk	D1 U14	PD3 (15) PG7 (15)	I/O	TTL	SSI module 2 clock.
SSI2Fss	D2 V12	PD2 (15) PG6 (15)	I/O	TTL	SSI module 2 frame signal.
SSI2XDAT0	C1 K15	PD1 (15) PG5 (15)	I/O	TTL	SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode).
SSI2XDAT1	C2 K17	PD0 (15) PG4 (15)	I/O	TTL	SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode).
SSI2XDAT2	B2 M16	PD7 (15) PG3 (15)	I/O	TTL	SSI Module 2 Bi-directional Data Pin 2.
SSI2XDAT3	B3 V11	PD6 (15) PG2 (15)	I/O	TTL	SSI Module 2 Bi-directional Data Pin 3.
SSI3Clk	T7 E3	PF3 (14) PQ0 (14)	I/O	TTL	SSI module 3 clock.
SSI3Fss	W6 E2	PF2 (14) PQ1 (14)	I/O	TTL	SSI module 3 frame signal.
SSI3XDAT0	V6 H4	PF1 (14) PQ2 (14)	I/O	TTL	SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode).
SSI3XDAT1	U6 M4	PF0 (14) PQ3 (14)	I/O	TTL	SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode).
SSI3XDAT2	V7 D6	PF4 (14) PP0 (15)	I/O	TTL	SSI Module 3 Bi-directional Data Pin 2.
SSI3XDAT3	W7 D7	PF5 (14) PP1 (15)	I/O	TTL	SSI Module 3 Bi-directional Data Pin 3.

20.3 Functional Description

The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The QSSI also supports the µDMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the µDMA module. µDMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 1407).

20.3.1 Bit Rate Generation

The QSSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (SysClk). The clock is first divided by an even prescale value CPSDVSR from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 1399). The clock is further divided by a value from 1 to 256, which is 1 + SCR, where SCR is the value programmed in the **SSI Control 0 (SSICR0)** register (see page 1391).

The frequency of the output clock SSInClk is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

Note: SYSCLK or ALTCLK is used as the source for the SSInClk depending on how the CS field in the **SSI Clock Configuration (SSICC)** register is configured. For master legacy mode, the SYSCLK or ALTCLK must be at least two times faster than the SSInClk, with the restriction that SSInClk cannot be faster than 60 MHz. For slave mode, SYSCLK or ALTCLK must be at least 12 times faster than the SSInClk. In slave legacy mode, the maximum frequency of SSInClk is 10 MHz.

See “Synchronous Serial Interface (SSI)” on page 2140 to view legacy SSI and QSSI timing parameters.

20.3.2 FIFO Operation

20.3.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 1396), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to a legacy SSI serial conversion and transmission to the attached slave or master, respectively, through the SSInDAT0/SSInTX pin.

In slave mode, the legacy SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the 8th most recent value in the transmit FIFO. If less than 8 values have been written to the transmit FIFO since the SSI module clock was enabled using the Rn bit in the **RCGSSI** register or if the QSSI is reset using the **SRSSI** register, then 0 is transmitted. Care should be taken to ensure that valid data is in the FIFO as needed. The QSSI can be configured to generate an interrupt or a µDMA request when the FIFO is empty.

Note: When operating in Legacy Mode, the QuadSSI's SSInXDAT0 signal functions as SSInTX.

20.3.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data using the legacy serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register. If the receive FIFO is full when the master or slave receives new data, the data is held off until the receive FIFO has space.

When configured as a master or slave, serial data received through the SSInDAT1/SSInRX pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

Note: When operating in Legacy Mode, the QSSI's SSInXDAT1 signal functions as SSInRX.

20.3.3 Advanced, Bi- and Quad- SSI Function

Bi-SSI uses two data pins, SSInXDAT0 and SSInXDAT1, that can be configured to receive or transmit data. In Quad-SSI mode, SSInXDAT0, SSInXDAT1, SSInXDAT2 and SSInXDAT3 allow four bits of data to be received or transmitted at once. Note that in bi- and quad-SSI data transfers are only half-duplex.

By programming the MODE bits in the **SSICR1** register, Advanced, Bi- or Quad- SSI can be enabled. A direction bit, DIR, is provided to program the direction of operation during a Bi- or Quad SSI-transaction. Since Bi- and Quad-SSI cannot be full duplex, the DIR bit defines whether or not the RX FIFO is disabled. In Advanced operation, if the QSSI module TX (write) mode is enabled, the RX FIFO is automatically prevented from receiving any data. When Advanced SSI is in RX (read) mode, it operates as a full-duplex interface.

In Bi- and Quad-SSI mode, because only 8-bit data is allowed, the DSS bit field must be programmed to 0x7 in the **SSICR0** register before transferring data to the Rx and TX FIFOs. For a data transmit, the 8-bit data packet is placed in a TX FIFO entry bits [7:0] and the mode of operation is inserted in the three most significant bits of the TX FIFO entry. The mode of operation bits [15:13] in the TX FIFO are used by the QSSI module for configuring the data on the proper pins. The following modes that may be placed on bits [15:13] of the FIFO entry are:

- Bi-SSI mode (0x1)
- Quad-SSI mode (0x2)
- Advanced SSI mode (0x3)

When data is first written to the TX FIFO, a SSInFss is asserted low indicating the start of a frame. At the end of transmission, bit 12 of the last data entry in the TX FIFO signifies whether a frame is ending. When the EOM bit is 1 it indicates a End of Message (EOM or STOP frame) and SSInFss is subsequently forced high. The EOM bit is cleared in the **SSICR1** register on the same clock that the write to TXFIFO is completed. An EOM bit value of 0 indicates no change in transmission. If TX FIFO is emptied and SSInFSS is still asserted low, it remains low but SSInCLK is not pulsed. Likewise, if SSInFss is high when the TX FIFO is empty, it remains high.

During a Bi-SSI transmit frame, data is shifted out by two bits and placed on the corresponding two SSInDATn pins. For a Quad-SSI transmit frame data is shifted out by four bits and placed on the corresponding four SSInDATn pins.

In Bi-, Quad- and Advanced SSI, the lower byte of the Rx FIFO contains received data. The upper byte contains no valid information.

Note: While the master is in Bi- or Quad-SSI mode, if the DSS bit in the **SSICR0** register is not set to 0x7, the QSSI module reverts to Legacy mode and behavior is not guaranteed.

The **SSICR1** register bits **DIR** and **MODE** are used to program what operation is needed for the next data bytes that are being loaded into the FIFO. Table 20-2 on page 1378 shows available modes of operation:

Table 20-2. QSSI Transaction Encodings

DIR	MODE	Operation
X	0x0	SSI Legacy operation supporting 4 to 16 data bits
0	0x1	Transmit (TX) Bi-SSI with 8-bits of packet data
0	0x2	Transmit (TX) Quad-SSI with 8-bits of packet data
0	0x3	Transmit (TX) Advanced SSI mode with 8-bits of packet data and write RX FIFO disabled
1	0x1	Receive (RX) Bi-SSI with 8-bits of packet data
1	0x2	Receive (RX) Quad-SSI with 8-bits of packet data
1	0x3	Full duplex Advance SSI with 8-bits of packet data

Note: $SPO = 0$ and $SPH = 0$ is the only frame structure allowed for Advanced, Bi- and Quad-mode.

Different transactions can follow one another in the FIFOs. The following transaction combinations are allowed:

- Legacy SSI mode (if configured for this mode, switching to any other alternate mode is not recommended)
- Advanced SSI mode followed by Bi-SSI mode
- Advanced SSI mode followed by Quad-SSI mode
- Advanced SSI mode followed by Bi-SSI mode followed by Advanced SSI mode
- Advanced SSI mode followed by Quad-SSI mode followed by Advanced SSI mode

Note that switching between Quad-SSI and Bi-SSI is not encouraged in a single transaction.

20.3.4 SSInFss Function

For enhanced modes of operation, the **SSInFss** signal can be programmed to assert low at the start of each byte transfer for one clock or the entire frame. This is configured by programming the **FSSHLDfrm** bit in the **SSICR1** register. The **EOM** bit is also provided to signify end of frame transmission. This bit is embedded in the TXFIFO entry for use at the interface to deassert **SSInFss** at the appropriate time. The **FSSHLDfrm** bit can also be used when operating in 8-bit Legacy SSI mode.

The functionality of the **FSSHLDfrm** bit for both Legacy SSI mode and the enhanced modes are as follows:

Table 20-3. SSInFss Functionality

Mode	FSSHLDfrm	Description
Legacy Mode	0	For Freescale format, with SPH = 0, the SSInFss signal is asserted low between continuous transfers. For SPH = 1, the SSInFss signal is deasserted (high) between continuous transfers. For TI format, the SSInFss signal is deasserted (high) after every data transfer.
	1	For Freescale format with any SPH value, the SSInFss signal is forced high between continuous transfers; it is asserted low when there is available data in the Tx FIFO; otherwise it is forced high to be ready for a new frame
Advanced/Bi-/Quad-SSI Mode	0	SSInFss is asserted low after every byte of data
	1	New data written to the TX FIFO notifies SSInFss to assert low until the Tx FIFO is empty.

20.3.5 High Speed Clock Operation

In master mode, QSSI module can enable a high speed clock by setting the HSCLKEN bit in the **SSI Control 1 (SSICR1)** register. In this mode of operation, SSInCLK from the QSSI master operation is reflected back as a loopback clock, HSPEEDCLK, to the QSSI module. This allows faster timing since the logic can be used to adjust clock to external data relationships. HSPEEDCLK captures RX data in a separate register . This allows the time between the clock as seen by a remote device and the internal clock to match more closely.

Receive data is captured in a separate register sampled on loop-back clock (HSPEEDCLK) and the RX FIFO write control registered on HSPEEDCLK. If the HSCKEN = 1, the corresponding shift register and FIFO write enable will be selected for use. This supports faster QSSI master speed.

Note: For proper functionality of high speed mode, the HSCLKEN bit in the **SSICR1** register should be set before any SSI data transfer or after applying a reset to the QSSI module. In addition, the SSE bit must be set to 0x1 before the HSCLKEN bit is set.

20.3.6 Interrupts

The QSSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service (when the transmit FIFO is half full or less)
- Receive FIFO service (when the receive FIFO is half full or more)
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission
- Receive DMA transfer complete
- Transmit DMA transfer complete

All of the interrupt events are ORed together before being sent to the interrupt controller, so the QSSI generates a single interrupt request to the controller regardless of the number of active interrupts. Each of the seven individual maskable interrupts can be masked by clearing the appropriate bit in the **SSI Interrupt Mask (SSIIM)** register (see page 1400). Setting the appropriate mask bit enables the interrupt.

The individual outputs, along with a combined interrupt output, allow use of either a global interrupt service routine or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 1402 and page 1404, respectively).

The RX FIFO has an associated time-out counter which starts to down count at the same time the RX FIFO is flagged as not empty by the **RNE** bit in the **SSISR** register. The counter is reset any time a new or next byte is written to the RX FIFO, thus the counter will continue to count down to zero unless there is new activity. The time-out period is 32 periods based on the period of **SSInClk**. When the counter reaches zero, a time-out interrupt bit, **RTRIS**, is set in the **SSIRIS** register. The time-out interrupt can be cleared by writing a 1 to the **RTIC** bit of the **SSI Interrupt Clear (SSIIC)** register or by emptying the RX FIFO. If the interrupt is cleared and there is residual data left in the RX FIFO or new data entries have been written, the timer count down initiates and the interrupt will be reasserted after 32 periods have been counted.

The End-of-Transmission (EOT) interrupt indicates that the data has been transmitted completely and is only valid for Master mode devices/operations. This interrupt can be used to indicate when it is safe to turn off the QSSI module clock or enter sleep mode. In addition, because transmitted data and received data complete at exactly the same time, the interrupt can also indicate that read data is ready immediately, without waiting for the receive FIFO time-out period to complete.

Note: In Freescale SPI mode only, a condition can be created where an EOT interrupt is generated for every byte transferred even if the FIFO is full. If the **EOT** bit has been set to 0 in an integrated slave QSSI and the **μDMA** has been configured to transfer data from this QSSI to a Master QSSI on the device using external loopback, an EOT interrupt is generated by the QSSI slave for every byte even if the FIFO is full.

20.3.7 Frame Formats

Each data frame is between 4 and 16 bits long in Legacy mode and 8-bits in Advanced/Bi-/Quad-SI mode and is transmitted starting with the MSB. There are two basic frame types that can be selected by programming the **FRF** bit in the **SSICR0** register:

- Texas Instruments synchronous serial
- Freescale SPI

Note: Advanced, Bi- and Quad-SI modules only supports Freescale mode when **SPH=0; SPO=0** and **DDS=0x8** in the **SSI Control 0 (SSICR0)** register.

For both formats, the serial clock (**SSInClk**) is held inactive while the QSSI is idle, and **SSInClk** transitions at the programmed frequency only during active transmission or reception of data. The idle state of **SSInClk** is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI frame format, the serial frame (**SSInFss**) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the **SSInFss** pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the QSSI and the off-chip slave device drive their output data on the rising edge of **SSInClk** and latch data from the other device on the falling edge.

The following table gives a synopsis of the features supported in each frame format when operating in Legacy Mode:

Table 20-4. Legacy Mode TI, Freescale SPI Frame Format Features

Feature	TI Mode	Freescale SPI Mode
Frame Hold	Not Available	Available
High Speed (Master RX Only)	Not Available	Available
SPO/SPH Configuration	Not Available	Available and can be used in combination with Frame Hold and High Speed Mode
Frequency (system clock : SSInCLK)	Master 1:2 Slave 1:12	Master 1:2 Slave 1:12

For Advanced, Bi- and Quad-SSI modes using the Freescale SPI Format or the Bi- and Quad-SSI modes using the TI format, the following features are supported:

- Frame Hold
- High Speed (Master RX Only)
- SPO/SPH Configuration with `SPO=0` and `SPH=0` only allowed
- Frequency (system clock : SSInCLK):
 - Master 1:2
 - Slave 1:12

20.3.7.1 Texas Instruments Synchronous Serial Frame Format

Figure 20-2 on page 1381 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

Figure 20-2. TI Synchronous Serial Frame Format (Single Transfer)

In this mode, `SSInClk` and `SSInFss` are forced Low, and the transmit data line `SSInDAT0/SSInTX` is tristated whenever the QSSI is idle. Once the bottom entry of the transmit FIFO contains data, `SSInFss` is pulsed High for one `SSInClk` period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of `SSInClk`, the MSB of the 4 to 16-bit data frame is shifted out on the `SSInDAT0/SSInTX` pin. Likewise, the MSB of the received data is shifted onto the `SSInDAT1/SSInRX` pin by the off-chip serial slave device.

Both the QSSI and the off-chip serial slave device then clock each data bit into their serial shifter on each falling edge of `SSInClk`. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of `SSInClk` after the LSB has been latched.

Figure 20-3 on page 1382 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

Figure 20-3. TI Synchronous Serial Frame Format (Continuous Transfer)

20.3.7.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the **SSInFss** signal behaves as a slave select. If operating in Legacy Mode and using the Freescale SPI Frame Format, the inactive state and phase of the **SSInClk** signal are programmable through the **SPO** and **SPH** bits in the **SSICR0** control register. If operating in Advanced/Bi-/Quad-SSI mode, the **SPO** and **SPH** bits must be programmed to 0.

SPO Clock Polarity Bit

When the **SPO** clock polarity control bit is clear, it produces a steady state Low value on the **SSInClk** pin. If the **SPO** bit is set, a steady state High value is placed on the **SSInClk** pin when data is not being transferred.

SPH Phase Control Bit

The **SPH** phase control bit selects the clock edge that captures data and allows it to change state. The state of this bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the **SPH** phase control bit is clear, data is captured on the first clock edge transition. If the **SPH** bit is set, data is captured on the second clock edge transition.

20.3.7.3 Freescale SPI Frame Format with **SPO=0** and **SPH=0**

Single and continuous transmission signal sequences for Freescale SPI format with **SPO=0** and **SPH=0** are shown in Figure 20-4 on page 1383 and Figure 20-5 on page 1383.

Note: This is the only Freescale SPI frame format configuration that can be used when operating in Advanced/Bi-/Quad-SSI mode.

Figure 20-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0

Note: Q is undefined.

Figure 20-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0

In this configuration, during idle periods:

- SSInClk is forced Low
- SSInFss is forced High
- The transmit data line SSInDAT0 / SSInTX is arbitrarily forced Low
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low, causing slave data to be enabled onto the SSInDAT1 / SSInRX input line of the master. The master SSInDAT0 / SSInTX output pad is enabled.

One half SSInClk period later, valid master data is transferred to the SSInDAT0 / SSInTX pin. Once both the master and slave data have been set, the SSInClk master clock pin goes High after one additional half SSInClk period.

The data is now captured on the rising and propagated on the falling edges of the SSInClk signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the SSInFss line is returned to its idle High state one SSInClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSInFss signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSInFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSInFss pin is returned to its idle state one SSInClk period after the last bit has been captured.

20.3.7.4 Freescale SPI Frame Format with SPO=0 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=0 and SPH=1 is shown in Figure 20-6 on page 1384, which covers both single and continuous transfers.

Note: This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

Figure 20-6. Freescale SPI Frame Format with SPO=0 and SPH=1

Note: Q is undefined.

In this configuration, during idle periods:

- SSInClk is forced Low
- SSInFss is forced High
- The transmit data line SSInDAT0 / SSInTX is arbitrarily forced Low
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low. The master SSInDAT0 / SSInTX output is enabled. After an additional one-half SSInClk period, both master and slave valid data are enabled onto their respective transmission lines. At the same time, the SSInClk is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the SSInClk signal.

In the case of a single word transfer, after all bits have been transferred, the SSInFss line is returned to its idle High state one SSInClk period after the last bit has been captured.

For continuous back-to-back transfers, the SSInFss pin is held Low between successive data words, and termination is the same as that of the single word transfer.

20.3.7.5 Freescale SPI Frame Format with SPO=1 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=1 and SPH=0 are shown in Figure 20-7 on page 1385 and Figure 20-8 on page 1385.

Note: This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

Figure 20-7. Freescale SPI Frame Format (Single Transfer) with SPO=1 and SPH=0

Note: Q is undefined.

Figure 20-8. Freescale SPI Frame Format (Continuous Transfer) with SPO=1 and SPH=0

In this configuration, during idle periods:

- SSInClk is forced High
- SSInFss is forced High
- The transmit data line SSInDAT0 / SSInTX is arbitrarily forced Low
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low, causing slave data to be immediately transferred onto the SSInDAT1/SSInRX line of the master. The master SSInDAT0/SSInTX output pad is enabled.

One-half period later, valid master data is transferred to the SSInDAT0/SSInTX line. Once both the master and slave data have been set, the SSInClk master clock pin becomes Low after one additional half SSInClk period, meaning that data is captured on the falling edges and propagated on the rising edges of the SSInClk signal.

In the case of a single word transmission, after all bits of the data word are transferred, the SSInFss line is returned to its idle High state one SSInClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSInFss signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is clear. Therefore, the master device must raise the SSInFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSInFss pin is returned to its idle state one SSInClk period after the last bit has been captured.

20.3.7.6 Freescale SPI Frame Format with SPO=1 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=1 and SPH=1 is shown in Figure 20-9 on page 1386, which covers both single and continuous transfers.

Note: This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

Figure 20-9. Freescale SPI Frame Format with SPO=1 and SPH=1

Note: Q is undefined.

In this configuration, during idle periods:

- SSInClk is forced High
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is arbitrarily forced Low
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low. The master SSInDAT0/SSInTX output pad is enabled. After an additional one-half SSInClk period, both master and slave data are enabled onto their respective transmission lines. At the same time, SSInClk is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SSInClk signal.

After all bits have been transferred, in the case of a single word transmission, the SSInFss line is returned to its idle high state one SSInClk period after the last bit has been captured.

For continuous back-to-back transmissions, the SSInFss pin remains in its active Low state until the final bit of the last word has been captured and then returns to its idle state as described above.

For continuous back-to-back transfers, the SSInFss pin is held Low between successive data words and termination is the same as that of the single word transfer.

20.3.8 DMA Operation

The QSSI peripheral provides an interface to the μDMA controller with separate channels for transmit and receive. The μDMA operation of the QSSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When μDMA operation is enabled, the QSSI asserts a μDMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever at least one empty location is in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst μDMA transfer requests are handled automatically by the μDMA controller depending how the μDMA channel is configured. To enable μDMA operation for the receive channel, the RXDMAE bit of the **DMA Control (SSIDMACTL)** register should be set. To enable μDMA operation for the transmit channel, the TXDMAE bit of **SSIDMACTL** should be set. If the μDMA is enabled and has completed a data transfer from the Tx FIFO, the DMATXRIS bit is set in the **SSIRIS** register. If a data transfer by the μDMA from the Rx FIFO completes, the DMARXRIS bit is set. The EOT bit in the **SSIRIS** register is also provided to indicate when the Tx FIFO is empty and the last bit has been transmitted out of the serializer.

See “Micro Direct Memory Access (μDMA)” on page 705 for more details about programming the μDMA controller.

20.4 Initialization and Configuration

To enable and initialize the QSSI, the following steps are necessary:

1. Enable the QSSI module using the **RCGCSSI** register (see page 406).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 398). To find out which GPIO port to enable, refer to Table 31-5 on page 2085.
3. Set the GPIO AFSEL bits for the appropriate pins (see page 799). To determine which GPIOs to configure, see Table 31-4 on page 2068.
4. Configure the PMCh fields in the **GPIOPCTL** register to assign the QSSI signals to the appropriate pins. See page 816 and Table 31-5 on page 2085.
5. Program the **GPIODEN** register to enable the pin's digital function. In addition, the drive strength, drain select and pull-up/pull-down functions must be configured. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 769 for more information.

Note: Pull-ups can be used to avoid unnecessary toggles on the QSSI pins, which can take the slave to a wrong state. In addition, if the SSIClk signal is programmed to steady state high through the SPO bit in the SSICR0 register, then software must also configure the GPIO port pin corresponding to the SSInClk signal as a pull-up in the **GPIO Pull-Up Select (GPIOPUR)** register, GPIO offset 0x510.

For each of the frame formats, the QSSI is configured using the following steps:

1. If initializing out of reset, ensure that the SSE bit in the **SSICR1** register is clear before making any configuration changes. Otherwise, configuration changes for Advanced SSI can be made while the SSE bit is set.
2. Select whether the QSSI is a master or slave:
 - a. For master operations, set the **SSICR1** register to 0x0000.0000.
 - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
 - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the QSSI clock source by writing to the **SSICC** register.
4. Configure the clock prescale divisor by writing the **SSICPSR** register.
5. Write the **SSICR0** register with the following configuration:
 - Serial clock rate (SCR)
 - Desired clock phase/polarity, if using Freescale SPI mode (SPH and SPO)
 - The protocol mode: Freescale SPI or TI SSF
 - The data size (DSS)
6. Optionally, configure the μDMA channel (see “Micro Direct Memory Access (μDMA)” on page 705) and enable the DMA option(s) in the **SSIDMACTL** register.
7. If this is the first initialization out of reset, enable the QSSI by setting the SSE bit in the **SSICR1** register.

As an example, assume the QSSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (SPO=1, SPH=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\begin{aligned} \text{SSInClk} &= \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR})) \\ 1 \times 10^6 &= 20 \times 10^6 / (\text{CPSDVSR} * (1 + \text{SCR})) \end{aligned}$$

In this case, if CPSDVSR=0x2, SCR must be 0x9.

The configuration sequence would be as follows:

1. Ensure that the **SSE** bit in the **SSICR1** register is clear.
2. Write the **SSICR1** register with a value of 0x0000.0000.
3. Write the **SSICPSR** register with a value of 0x0000.0002.
4. Write the **SSICR0** register with a value of 0x0000.09C7.
5. The QSSI is then enabled by setting the **SSE** bit in the **SSICR1** register.

20.4.1 Enhanced Mode Configuration

If the QSSI module supports the Advanced/Bi-/Quad features, then these modes can be enabled after initializing the QSSI module. Below is an example of configuring the QSSI to transmit two data bytes in Advanced SSI mode followed by 2 bytes in Bi-SSI mode:

1. Set the **MODE** bit to 0x3, and the **FSSHLDFA** bit to 1 in the **SSICR1** register. To operate in the master mode, program the **MS** bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
2. Write one data byte to the TX FIFO; set the **EOM** bit to 1 and write the second data byte to the Tx FIFO.
3. Set the **MODE** bit to 0x1 and the **FSSHLDFA** bit to 1 in the **SSICR1** register. To operate in the master mode, program the **MS** bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
4. Fill the Tx FIFO with one data byte.
5. Set the **EOM** bit in the **SSICR1** register.
6. Fill the Tx FIFO with one data byte.

20.5 Register Map

Table 20-5 on page 1389 lists the QSSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that QSSI module's base address:

- QSSI0: 0x4000.8000
- QSSI1: 0x4000.9000
- QSSI2: 0x4000.A000
- QSSI3: 0x4000.B000

Note that the QSSI module clock must be enabled before the registers can be programmed (see page 406). The **Rn** bit of the **PRSSI** register must be read as 0x1 before any QSSI module registers are accessed.

Table 20-5. SSI Register Map

Offset	Name	Type	Reset	Description	See page
0x000	SSICR0	RW	0x0000.0000	QSSI Control 0	1391

Table 20-5. SSI Register Map (continued)

Offset	Name	Type	Reset	Description	See page
0x004	SSICR1	RW	0x0000.0000	QSSI Control 1	1393
0x008	SSIDR	RW	0x0000.0000	QSSI Data	1396
0x00C	SSISR	RO	0x0000.0003	QSSI Status	1397
0x010	SSICPSR	RW	0x0000.0000	QSSI Clock Prescale	1399
0x014	SSIIM	RW	0x0000.0000	QSSI Interrupt Mask	1400
0x018	SSIRIS	RO	0x0000.0008	QSSI Raw Interrupt Status	1402
0x01C	SSIMIS	RO	0x0000.0000	QSSI Masked Interrupt Status	1404
0x020	SSIICR	W1C	0x0000.0000	QSSI Interrupt Clear	1406
0x024	SSIDMACTL	RW	0x0000.0000	QSSI DMA Control	1407

20.6 Register Descriptions

The remainder of this section lists and describes the QSSI registers, in numerical order by address offset.

Register 1: QSSI Control 0 (SSICR0), offset 0x000

The **SSICR0** register contains bit fields that control various functions within the QSSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

QSSI Control 0 (SSICR0)

QSSI0 base: 0x4000.8000
 QSSI1 base: 0x4000.9000
 QSSI2 base: 0x4000.A000
 QSSI3 base: 0x4000.B000
 Offset 0x000
 Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
15:8	SCR	RW	0x00	<p>QSSI Serial Clock Rate</p> <p>This bit field is used to generate the transmit and receive bit rate of the QSSI. The bit rate is:</p> $BR = SysClk / (CPSDVSR * (1 + SCR))$ <p>where CPSDVSR is an even value from 2-254 programmed in the SSICPSR register, and SCR is a value from 0-255.</p>						
7	SPH	RW	0	<p>QSSI Serial Clock Phase</p> <p>This bit is only applicable to the Freescale SPI Format.</p> <p>The SPH control bit selects the clock edge that captures data and allows it to change state. This bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Data is captured on the first clock edge transition.</td> </tr> <tr> <td>1</td> <td>Data is captured on the second clock edge transition.</td> </tr> </tbody> </table>	Value	Description	0	Data is captured on the first clock edge transition.	1	Data is captured on the second clock edge transition.
Value	Description									
0	Data is captured on the first clock edge transition.									
1	Data is captured on the second clock edge transition.									
6	SPO	RW	0	<p>QSSI Serial Clock Polarity</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>A steady state Low value is placed on the SSInClk pin.</td> </tr> <tr> <td>1</td> <td>A steady state High value is placed on the SSInClk pin when data is not being transferred.</td> </tr> </tbody> </table> <p>Note: If this bit is set, then software must also configure the GPIO port pin corresponding to the SSInClk signal as a pull-up in the GPIO Pull-Up Select (GPIOPUR) register, GPIO offset 0x510.</p>	Value	Description	0	A steady state Low value is placed on the SSInClk pin.	1	A steady state High value is placed on the SSInClk pin when data is not being transferred.
Value	Description									
0	A steady state Low value is placed on the SSInClk pin.									
1	A steady state High value is placed on the SSInClk pin when data is not being transferred.									

Bit/Field	Name	Type	Reset	Description
5:4	FRF	RW	0x0	QSSI Frame Format Select Note: When operating in Advanced/Bi-/Quad-SSI mode these bits must be programmed to 0x0 (Freescale SPI Frame Format).
				Value Frame Format 0x0 Freescale SPI Frame Format 0x1 Texas Instruments Synchronous Serial Frame Format 0x2-0x3 Reserved
3:0	DSS	RW	0x0	QSSI Data Size Select Note: When operating in Advanced, Bi- or Quad-SSI, data size can only be 8-bit. All other fields will be ignored.
				Value Data Size 0x0-0x2 Reserved 0x3 4-bit data 0x4 5-bit data 0x5 6-bit data 0x6 7-bit data 0x7 8-bit data 0x8 9-bit data 0x9 10-bit data 0xA 11-bit data 0xB 12-bit data 0xC 13-bit data 0xD 14-bit data 0xE 15-bit data 0xF 16-bit data

Register 2: QSSI Control 1 (SSICR1), offset 0x004

The **SSICR1** register contains bit fields that control various functions within the QSSI module. Master and slave mode functionality is controlled by this register.

QSSI Control 1 (SSICR1)

QSS10 base: 0x4000.8000
QSS11 base: 0x4000.9000
QSS12 base: 0x4000.A000
QSS13 base: 0x4000.B000
Offset 0x004
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:12	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
11	EOM	RW	0	<p>Stop Frame (End of Message)</p> <p>This bit is applicable when MODE is set to Advanced, Bi- or Quad- SSI. This bit is inserted into bit 12 of the TXFIFO data entry by the QSSI module.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No change is transmission status.</td></tr> <tr> <td>1</td><td>End of message (Stop Frame).</td></tr> </tbody> </table>	Value	Description	0	No change is transmission status.	1	End of message (Stop Frame).
Value	Description									
0	No change is transmission status.									
1	End of message (Stop Frame).									
10	FSSHLDfrm	RW	0	<p>FSS Hold Frame</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Pulse SSInFss at every byte (the DSS bit in the SSICR0 register must be set to 0x7 (data size 8 bits) in this configuration)</td></tr> <tr> <td>1</td><td>Hold SSInFss for the whole frame</td></tr> </tbody> </table>	Value	Description	0	Pulse SSInFss at every byte (the DSS bit in the SSICR0 register must be set to 0x7 (data size 8 bits) in this configuration)	1	Hold SSInFss for the whole frame
Value	Description									
0	Pulse SSInFss at every byte (the DSS bit in the SSICR0 register must be set to 0x7 (data size 8 bits) in this configuration)									
1	Hold SSInFss for the whole frame									
9	HSCLKEN	RW	0	<p>High Speed Clock Enable</p> <p>High speed clock enable is available only when operating as a master.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Use Input Clock</td></tr> <tr> <td>1</td><td>Use High Speed Clock</td></tr> </tbody> </table> <p>Note: For proper functionality of high speed mode, the HSCLKEN bit in the SSICR1 register should be set before any SSI data transfer or after applying a reset to the QSSI module. In addition, the SSE bit must be set to 0x1 before the HSCLKEN bit is set.</p>	Value	Description	0	Use Input Clock	1	Use High Speed Clock
Value	Description									
0	Use Input Clock									
1	Use High Speed Clock									

Bit/Field	Name	Type	Reset	Description										
8	DIR	RW	0	<p>QSSI Direction of Operation</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>TX (Transmit Mode) write direction</td></tr> <tr> <td>1</td><td>RX (Receive Mode) read direction</td></tr> </tbody> </table>	Value	Description	0	TX (Transmit Mode) write direction	1	RX (Receive Mode) read direction				
Value	Description													
0	TX (Transmit Mode) write direction													
1	RX (Receive Mode) read direction													
7:6	MODE	RW	0x0	<p>QSSI Mode</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>Legacy SSI mode</td></tr> <tr> <td>0x1</td><td>Bi-SSI mode</td></tr> <tr> <td>0x2</td><td>Quad-SSI Mode</td></tr> <tr> <td>0x3</td><td>Advanced SSI Mode with 8-bit packet size</td></tr> </tbody> </table>	Value	Description	0x0	Legacy SSI mode	0x1	Bi-SSI mode	0x2	Quad-SSI Mode	0x3	Advanced SSI Mode with 8-bit packet size
Value	Description													
0x0	Legacy SSI mode													
0x1	Bi-SSI mode													
0x2	Quad-SSI Mode													
0x3	Advanced SSI Mode with 8-bit packet size													
5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										
4	EOT	RW	0	<p>End of Transmission</p> <p>This bit is only valid for Master mode devices and operations (MS = 0x0).</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The TXRIS interrupt indicates that the transmit FIFO is half full or less.</td></tr> <tr> <td>1</td><td>The End of Transmit interrupt mode for the TXRIS interrupt is enabled.</td></tr> </tbody> </table> <p>Note: In Freescale SPI mode only, a condition can be created where an EOT interrupt is generated for every byte transferred even if the FIFO is full. If the EOT bit has been set to 0 in an integrated slave QSSI and the µDMA has been configured to transfer data from this QSSI to a Master QSSI on the device using external loopback, an EOT interrupt is generated by the QSSI slave for every byte even if the FIFO is full.</p>	Value	Description	0	The TXRIS interrupt indicates that the transmit FIFO is half full or less.	1	The End of Transmit interrupt mode for the TXRIS interrupt is enabled.				
Value	Description													
0	The TXRIS interrupt indicates that the transmit FIFO is half full or less.													
1	The End of Transmit interrupt mode for the TXRIS interrupt is enabled.													
3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										
2	MS	RW	0	<p>QSSI Master/Slave Select</p> <p>This bit selects Master or Slave mode and can be modified only when the QSSI is disabled (SSE=0).</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The QSSI is configured as a master.</td></tr> <tr> <td>1</td><td>The QSSI is configured as a slave.</td></tr> </tbody> </table>	Value	Description	0	The QSSI is configured as a master.	1	The QSSI is configured as a slave.				
Value	Description													
0	The QSSI is configured as a master.													
1	The QSSI is configured as a slave.													

Bit/Field	Name	Type	Reset	Description
1	SSE	RW	0	<p>QSSI Synchronous Serial Port Enable</p> <p>Value Description</p> <p>0 QSSI operation is disabled.</p> <p>1 QSSI operation is enabled.</p> <p>Note: The HSCLKEN bit in the SSICR1 register should be set only after applying reset to the QSSI module and enabling the QSSI by setting the SSE bit, and before any SSI data transfer. All other bits in the SSICR1 register and all bits in SSICR0 register can only be programmed when the SSE is clear.</p>
0	LBM	RW	0	<p>QSSI Loopback Mode</p> <p>Value Description</p> <p>0 Normal serial port operation enabled.</p> <p>1 Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.</p>

Register 3: QSSI Data (SSIDR), offset 0x008

Important: This register is read-sensitive. See the register description for details.

The **SSIDR** register is 16-bits wide. When the **SSIDR** register is read, the entry in the receive FIFO that is pointed to by the current FIFO read pointer is accessed. When a data value is removed by the QSSI receive logic from the incoming data frame, it is placed into the entry in the receive FIFO pointed to by the current FIFO write pointer.

When the **SSIDR** register is written to, the entry in the transmit FIFO that is pointed to by the write pointer is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. Each data value is loaded into the transmit serial shifter, then serially shifted out onto the SSInDAT0/SSInTX pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

QSSI Data (SSIDR)

QSSI0 base: 0x4000.8000

QSSI1 base: 0x4000.9000

QSSI2 base: 0x4000.A000

QSSI3 base: 0x4000.B000

Offset 0x008

Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:16 reserved RO 0x0000 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

15:0 DATA RW 0x0000 QSSI Receive/Transmit Data
A read operation reads the receive FIFO. A write operation writes the transmit FIFO.

Software must right-justify data when the QSSI is programmed for a data size that is less than 16 bits. Unused bits at the top are ignored by the transmit logic. The receive logic automatically right-justifies the data.

Register 4: QSSI Status (SSISR), offset 0x00C

The **SSISR** register contains bits that indicate the FIFO fill status and the QSSI busy status.

QSSI Status (SSISR)

QSSI0 base: 0x4000.8000

QSSI1 base: 0x4000.9000

QSSI2 base: 0x4000.A000

QSSI3 base: 0x4000.B000

Offset 0x00C

Type RO, reset 0x0000.0003

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	BSY	RO	0	QSSI Busy Bit
		Value	Description	
		0	The QSSI is idle.	
		1	The QSSI is currently transmitting and/or receiving a frame, or the transmit FIFO is not empty.	
3	RFF	RO	0	QSSI Receive FIFO Full
		Value	Description	
		0	The receive FIFO is not full.	
		1	The receive FIFO is full.	
2	RNE	RO	0	QSSI Receive FIFO Not Empty
		Value	Description	
		0	The receive FIFO is empty.	
		1	The receive FIFO is not empty.	
1	TNF	RO	1	QSSI Transmit FIFO Not Full
		Value	Description	
		0	The transmit FIFO is full.	
		1	The transmit FIFO is not full.	

Bit/Field	Name	Type	Reset	Description
0	TFE	RO	1	QSSI Transmit FIFO Empty
Value Description				
			0	The transmit FIFO is not empty.
			1	The transmit FIFO is empty.

Register 5: QSSI Clock Prescale (SSICPSR), offset 0x010

The **SSICPSR** register specifies the division factor which is used to derive the SSInClk from the system clock. The clock is further divided by a value from 1 to 256, which is $1 + \text{SCR}$. SCR is programmed in the **SSICR0** register. The frequency of the SSInClk is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

QSSI Clock Prescale (SSICPSR)

QSSI0 base: 0x4000.8000

QSSI1 base: 0x4000.9000

QSSI2 base: 0x4000.A000

QSSI3 base: 0x4000.B000

Offset 0x010

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CPSDVSR	RW	0x00	QSSI Clock Prescale Divisor This value must be an even number from 2 to 254, depending on the frequency of SSInClk. The LSB always returns 0 on reads.

Register 6: QSSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared on reset.

On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit clears the mask, enabling the interrupt to be sent to the interrupt controller. Clearing a bit sets the corresponding mask, preventing the interrupt from being signaled to the controller.

QSSI Interrupt Mask (SSIIM)

QSSI0 base: 0x4000.8000

QSSI1 base: 0x4000.9000

QSSI2 base: 0x4000.A000

QSSI3 base: 0x4000.B000

Offset 0x014

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	EOTIM	RW	0	End of Transmit Interrupt Mask
	Value	Description		
	0	The end of transmit interrupt is masked.		
	1	The end of transmit interrupt is not masked.		
5	DMATXIM	RW	0	QSSI Transmit DMA Interrupt Mask
	Value	Description		
	0	The transmit DMA interrupt is masked.		
	1	The transmit DMA interrupt is not masked.		
4	DMARXIM	RW	0	QSSI Receive DMA Interrupt Mask
	Value	Description		
	0	The receive DMA interrupt is masked.		
	1	The receive DMA interrupt is not masked.		
3	TXIM	RW	0	QSSI Transmit FIFO Interrupt Mask
	Value	Description		
	0	The transmit FIFO interrupt is masked.		
	1	The transmit FIFO interrupt is not masked.		

Bit/Field	Name	Type	Reset	Description
2	RXIM	RW	0	QSSI Receive FIFO Interrupt Mask Value Description 0 The receive FIFO interrupt is masked. 1 The receive FIFO interrupt is not masked.
1	RTIM	RW	0	QSSI Receive Time-Out Interrupt Mask Value Description 0 The receive FIFO time-out interrupt is masked. 1 The receive FIFO time-out interrupt is not masked.
0	RORIM	RW	0	QSSI Receive Overrun Interrupt Mask Value Description 0 The receive FIFO overrun interrupt is masked. 1 The receive FIFO overrun interrupt is not masked.

Register 7: QSSI Raw Interrupt Status (SSIRIS), offset 0x018

The **SSIRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

QSSI Raw Interrupt Status (SSIRIS)

QSSI0 base: 0x4000.8000

QSSI1 base: 0x4000.9000

QSSI2 base: 0x4000.A000

QSSI3 base: 0x4000.B000

Offset 0x018

Type RO, reset 0x0000.0008

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	EOTRIS	RO	0	End of Transmit Raw Interrupt Status Value Description 0 No interrupt. 1 The transmit FIFO is empty, and the last bit has been transmitted out of the serializer. This bit is cleared when a 1 is written to the EOTIC bit in the SSI Interrupt Clear (SSIICR) register.
5	DMATXRIS	RO	0	QSSI Transmit DMA Raw Interrupt Status Value Description 0 No interrupt. 1 The transmit DMA has completed. This bit is cleared when a 1 is written to the DMATXIC bit in the SSI Interrupt Clear (SSIICR) register.
4	DMARXRIS	RO	0	QSSI Receive DMA Raw Interrupt Status Value Description 0 No interrupt. 1 The receive DMA has completed. This bit is cleared when a 1 is written to the DMARXIC bit in the SSI Interrupt Clear (SSIICR) register.

Bit/Field	Name	Type	Reset	Description						
3	TXRIS	RO	1	<p>QSSI Transmit FIFO Raw Interrupt Status</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No interrupt.</td></tr> <tr> <td>1</td><td>If the EOT bit in the SSICR1 register is clear, the transmit FIFO is half empty or less. If the EOT bit is set, the transmit FIFO is empty, and the last bit has been transmitted out of the serializer.</td></tr> </tbody> </table> <p>This bit is cleared when the transmit FIFO is more than half full (if the EOT bit is clear) or when it has any data in it (if the EOT bit is set).</p>	Value	Description	0	No interrupt.	1	If the EOT bit in the SSICR1 register is clear, the transmit FIFO is half empty or less. If the EOT bit is set, the transmit FIFO is empty, and the last bit has been transmitted out of the serializer.
Value	Description									
0	No interrupt.									
1	If the EOT bit in the SSICR1 register is clear, the transmit FIFO is half empty or less. If the EOT bit is set, the transmit FIFO is empty, and the last bit has been transmitted out of the serializer.									
2	RXRIS	RO	0	<p>QSSI Receive FIFO Raw Interrupt Status</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No interrupt.</td></tr> <tr> <td>1</td><td>The receive FIFO is half full or more.</td></tr> </tbody> </table> <p>This bit is cleared when the receive FIFO is less than half full.</p>	Value	Description	0	No interrupt.	1	The receive FIFO is half full or more.
Value	Description									
0	No interrupt.									
1	The receive FIFO is half full or more.									
1	RTRIS	RO	0	<p>QSSI Receive Time-Out Raw Interrupt Status</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No interrupt.</td></tr> <tr> <td>1</td><td>The receive time-out has occurred.</td></tr> </tbody> </table> <p>This bit is cleared when a 1 is written to the RTIC bit in the SSI Interrupt Clear (SSICR) register.</p>	Value	Description	0	No interrupt.	1	The receive time-out has occurred.
Value	Description									
0	No interrupt.									
1	The receive time-out has occurred.									
0	RORRIS	RO	0	<p>QSSI Receive Overrun Raw Interrupt Status</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No interrupt.</td></tr> <tr> <td>1</td><td>The receive FIFO has overflowed</td></tr> </tbody> </table> <p>This bit is cleared when a 1 is written to the RORIC bit in the SSI Interrupt Clear (SSICR) register.</p>	Value	Description	0	No interrupt.	1	The receive FIFO has overflowed
Value	Description									
0	No interrupt.									
1	The receive FIFO has overflowed									

Register 8: QSSI Masked Interrupt Status (SSIMIS), offset 0x01C

The **SSIMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

QSSI Masked Interrupt Status (SSIMIS)

QSSI0 base: 0x4000.8000
 QSSI1 base: 0x4000.9000
 QSSI2 base: 0x4000.A000
 QSSI3 base: 0x4000.B000
 Offset 0x01C
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	EOTMIS	RO	0	End of Transmit Masked Interrupt Status
	Value	Description		
	0	An interrupt has not occurred or is masked.		
	1	An unmasked interrupt was signaled due to the transmission of the last data bit.		
	This bit is cleared when a 1 is written to the EOTIC bit in the SSI Interrupt Clear (SSIIICR) register.			
5	DMATXMS	RO	0	QSSI Transmit DMA Masked Interrupt Status
	Value	Description		
	0	An interrupt has not occurred or is masked.		
	1	An unmasked interrupt was signaled due to the completion of the transmit DMA.		
	This bit is cleared when a 1 is written to the DMATXIC bit in the SSI Interrupt Clear (SSIIICR) register.			
4	DMARXMIS	RO	0	QSSI Receive DMA Masked Interrupt Status
	Value	Description		
	0	An interrupt has not occurred or is masked.		
	1	An unmasked interrupt was signaled due to the completion of the receive DMA.		
	This bit is cleared when a 1 is written to the DMARXIC bit in the SSI Interrupt Clear (SSIIICR) register.			

Bit/Field	Name	Type	Reset	Description						
3	TXMIS	RO	0	<p>QSSI Transmit FIFO Masked Interrupt Status</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>An interrupt has not occurred or is masked.</td></tr> <tr> <td>1</td><td>An unmasked interrupt was signaled due to the transmit FIFO being half empty or less (if the EOT bit is clear) or due to the transmission of the last data bit (if the EOT bit is set).</td></tr> </tbody> </table> <p>This bit is cleared when the transmit FIFO is more than half empty (if the EOT bit is clear) or when it has any data in it (if the EOT bit is set).</p>	Value	Description	0	An interrupt has not occurred or is masked.	1	An unmasked interrupt was signaled due to the transmit FIFO being half empty or less (if the EOT bit is clear) or due to the transmission of the last data bit (if the EOT bit is set).
Value	Description									
0	An interrupt has not occurred or is masked.									
1	An unmasked interrupt was signaled due to the transmit FIFO being half empty or less (if the EOT bit is clear) or due to the transmission of the last data bit (if the EOT bit is set).

21 Inter-Integrated Circuit (I²C) Interface

The Inter-Integrated Circuit (I²C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I²C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I²C bus may also be used for system testing and diagnostic purposes in product development and manufacturing. The TM4C129XKCZAD microcontroller includes providing the ability to communicate (both transmit and receive) with other I²C devices on the bus.

The TM4C129XKCZAD controller includes I²C modules with the following features:

- Devices on the I²C bus can be designated as either a master or a slave
 - Supports both transmitting and receiving data as either a master or a slave
 - Supports simultaneous master and slave operation
- Four I²C modes
 - Master transmit
 - Master receive
 - Slave transmit
 - Slave receive
- Two 8-entry FIFOs for receive and transmit data
 - FIFOs can be independently assigned to master or slave
- Four transmission speeds:
 - Standard (100 Kbps)
 - Fast-mode (400 Kbps)
 - Fast-mode plus (1 Mbps)
 - High-speed mode (3.33 Mbps)
- Glitch suppression
- SMBus support through software
 - Clock low timeout interrupt
 - Dual slave address capability
 - Quick command capability
- Master and slave interrupt generation
 - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)

- Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Separate channels for transmit and receive
 - Ability to execute single data transfers or burst data transfers using the RX and TX FIFOs in the I²C

21.1 Block Diagram

Figure 21-1. I²C Block Diagram

21.2 Signal Description

The following table lists the external signals of the I²C interface and describes the function of each. The I²C interface signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the I²C signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the I²C function. The number in parentheses is the encoding that must be programmed into the PMCn field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the I²C signal to the specified GPIO port pin. Note that the I²CSDA pin should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 769.

Table 21-1. I²C Signals (212BGA)

I ² C9SDA	W3 B7	PA1 (2) PE7 (2)	I/O	OD	I ² C module 9 data.

21.3 Functional Description

Each I²C module is comprised of both master and slave functions and is identified by a unique address. A master-initiated communication generates the clock signal, SCL. For proper operation, the SDA pin must be configured as an open-drain signal. Due to the internal circuitry that supports high-speed operation, the SCL pin must not be configured as an open-drain signal, although the internal circuitry causes it to act as if it were an open drain signal. Both SDA and SCL signals must be connected to a positive supply voltage using a pull-up resistor. A typical I²C bus configuration is shown in Figure 21-2. Refer to the *I²C-bus specification and user manual* to determine the size of the pull-ups needed for proper operation.

See “Inter-Integrated Circuit (I²C) Interface” on page 2143 for I²C timing diagrams.

Figure 21-2. I²C Bus Configuration

21.3.1 I²C Bus Functional Overview

The I²C bus uses only two signals: SDA and SCL, named I²CSDA and I²CSCL on TM4C129XKCZAD microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I^2C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 1426) is unrestricted, but each data byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

21.3.1.1 START and STOP Conditions

The protocol of the I^2C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 21-3.

Figure 21-3. START and STOP Conditions

The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I^2C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due to an error), the interrupt pin becomes active and the data may be read from the **I^2C Master Data (I2CMDR)** register. When the I^2C module operates in Master receiver mode, the ACK bit is normally set causing the I^2C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I^2C bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, the STARTRIS and STOPRIS bits in the **I^2C Slave Raw Interrupt Status (I2CSRIS)** register indicate detection of start and stop conditions on the bus and the **I^2C Slave Masked Interrupt Status (I2CSMIS)** register can be configured to allow STARTRIS and STOPRIS to be promoted to controller interrupts (when interrupts are enabled).

21.3.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 21-4. After the START condition, a slave address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the **I2CMSA** register). If the R/S bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/transmit formats are then possible within a single transfer.

Figure 21-4. Complete Data Transfer with a 7-Bit Address

The first seven bits of the first byte make up the slave address (see Figure 21-5). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

Figure 21-5. R/S Bit in First Byte

21.3.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 21-6).

Figure 21-6. Data Validity During Bit Transfer on the I²C Bus

21.3.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in "Data Validity" on page 1427.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

If the slave is required to provide a manual ACK or NACK, the **I²C Slave ACK Control (I2CSACKCTL)** register allows the slave to NACK for invalid data or command or ACK for valid data or command. When this operation is enabled, the MCU slave module I²C clock is pulled low after the last data bit until this register is written with the indicated response.

21.3.1.5 Repeated Start

The I²C master module has the capability of executing a repeated START (transmit or receive) after an initial transfer has occurred.

A repeated start sequence for a Master transmit is as follows:

1. When the device is in the idle state, the Master writes the slave address to the **I2CMSCA** register and configures the R/S bit for the desired transfer type.
2. Data is written to the **I2CMDR** register.
3. When the **BUSY** bit in the **I2CMCS** register is 0 , the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSCA** register and then writes 0x3 to initiate the repeated START.

A repeated start sequence for a Master receive is similar:

1. When the device is in idle, the Master writes the slave address to the **I2CMSCA** register and configures the R/S bit for the desired transfer type.
2. The master reads data from the **I2CMDR** register.
3. When the **BUSY** bit in the **I2CMCS** register is 0 , the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSCA** register and then writes 0x3 to initiate the repeated START.

For more information on repeated START, refer to Figure 21-12 on page 1441 and Figure 21-13 on page 1442.

21.3.1.6 Clock Low Timeout (CLTO)

The I²C slave can extend the transaction by pulling the clock low periodically to create a slow bit transfer rate. The I²C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the **I²C Master Clock Low Timeout Count (I2CMCLKOCNT)** register. The lower four bits are not user visible and are 0x0. The CNTL value programmed in the **I2CMCLKOCNT** register has to be greater than 0x01. The application can program the eight most significant bits of the counter to reflect the acceptable cumulative low period in transaction. The count is loaded at the START condition and counts down on each falling edge of the internal bus clock of the Master. Note that the internal bus clock generated for this counter keeps running at the programmed I²C speed even if SCL is held low on the bus. Upon reaching terminal count, the master state machine forces ABORT on the bus by issuing a STOP condition at the instance of SCL and SDA release.

As an example, if an I²C module was operating at 100 kHz speed, programming the **I2CMCLKOCNT** register to 0xDA would translate to the value 0xDA0 since the lower four bits are set to 0x0. This would translate to a decimal value of 3488 clocks or a cumulative clock low period of 34.88 ms at 100 kHz.

The **CLKRIS** bit in the **I²C Master Raw Interrupt Status (I2CMRIS)** register is set when the clock timeout period is reached, allowing the master to start corrective action to resolve the remote slave state. In addition, the **CLKTO** bit in the **I²C Master Control/Status (I2CMCS)** register is set; this bit

is cleared when a STOP condition is sent or during the I²C master reset. The status of the raw SDA and SCL signals are readable by software through the SDA and SCL bits in the **I²C Master Bus Monitor (I2CMBMON)** register to help determine the state of the remote slave.

In the event of a CLTO condition, application software must choose how it intends to attempt bus recovery. Most applications may attempt to manually toggle the I²C pins to force the slave to let go of the clock signal (a common solution is to attempt to force a STOP on the bus). If a CLTO is detected before the end of a burst transfer, and the bus is successfully recovered by the master, the master hardware attempts to finish the pending burst operation. Depending on the state of the slave after bus recovery, the actual behavior on the bus varies. If the slave resumes in a state where it can acknowledge the master (essentially, where it was before the bus hang), it continues where it left off. However, if the slave resumes in a reset state (or if a forced STOP by the master causes the slave to enter the idle state), it may ignore the master's attempt to complete the burst operation and NAK the first data byte that the master sends or requests.

Since the behavior of slaves cannot always be predicted, it is suggested that the application software always write the STOP bit in the **I²C Master Configuration (I2CMCR)** register during the CLTO interrupt service routine. This limits the amount of data the master attempts to send or receive upon bus recovery to a single byte, and after the single byte is on the wire, the master issues a STOP. An alternative solution is to have the application software reset the I²C peripheral before attempting to manually recover the bus. This solution allows the I²C master hardware to be returned to a known good (and idle) state before attempting to recover a stuck bus and prevents any unwanted data from appearing on the wire.

Note: The Master Clock Low Timeout counter counts for the entire time SCL is held Low continuously. If SCL is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the **I2CMCLKOCNT** register and begins counting down from this value.

21.3.1.7 Dual Address

The I²C interface supports dual address capability for the slave. The additional programmable address is provided and can be matched if enabled. In legacy mode with dual address disabled, the I²C slave provides an ACK on the bus if the address matches the OAR field in the **I2CSOAR** register. In dual address mode, the I²C slave provides an ACK on the bus if either the OAR field in the **I2CSOAR** register or the OAR2 field in the **I2CSOAR2** register is matched. The enable for dual address is programmable through the OAR2EN bit in the **I2CSOAR2** register and there is no disable on the legacy address.

The OAR2SEL bit in the **I2CSCSR** register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, it indicates either legacy operation or no address match.

21.3.1.8 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a 1 (High) on SDA, while another master transmits a 0 (Low), switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

If arbitration is lost when the I²C master is initiating a BURST with the TX FIFO enabled, the application should execute the following steps to correctly handle the arbitration loss:

1. Flush and disable the TX FIFO
2. Clear and mask the TXFE interrupt by clearing the TXFEIM bit in the **I2CMIMR** register.

Once the bus is IDLE, the TXFIFO can be filled and enabled, the TXFE bit can be unmasked and a new BURST transaction can be initiated.

21.3.1.9 Glitch Suppression in Multi-Master Configuration

When a multi-master configuration is being used, the PULSEL bit in the **I2CMTPR** register can be programmed to provide glitch suppression on the SCL and SDA lines and assure proper signal values. The glitch suppression value is in terms of buffered system clocks. Note that all signals will be delayed internally when glitch suppression is nonzero. For example, if PULSEL is set to 0x7, 31 clocks should be added onto the calculation for the expected transaction time.

21.3.1.10 SMBus Operation

The SMBus interface is based on the I²C protocol; however, some differences exist between the two. These differences must be handled through software in order to make sure the SMBus protocol, including timing specifications, is met. Note that the SMBus 2.0 specification limits the maximum frequency of the interface to 100 KHz, as a result, I²C Standard speed operation is used for SMBus.

The SMBus/ I²C slave can extend the transaction if it is not ready by pulling the clock low. The SMBus specification allows the maximum timeout for such elongated transaction to be between 25 to 35 ms. The I²C specification does not have this requirement. The I²C module supports a programmable count to support clock-low timeout for the master to error out and take appropriate action as required. This feature is explained in “Clock Low Timeout (CLTO)” on page 1428. Note that if transactions are extended, a timeout period should be programmed in the **I2CMCLKOCNT** register, and the CLKRIS bit in the **I2CMRIS** register should not be masked.

Unlike the I²C slave, the SMBus slave must respond with an ACK response to its address regardless of whether it is ready or not. As a result, the I²C slave sends an ACK response to its address and a NACK response on the data byte if it is not ready. The ARBLST bit in the **I2CMCS** register is set if there were any issues with the transfer. In addition, the slave can send a NACK at any time to force the master to stop sending additional bytes.

The I²C Interface supports μDMA for efficient data handling. The μDMA operation needs FIFOs to be enabled for appropriate transfer type to perform I²C Master for burst transfers and all types of Slave transfers. The I²C interface is supported by two channels, one for Rx (I²C to Memory) and one for Tx (Memory to I²C) transfers.. See “FIFO and μDMA Operation” on page 1434 for more information.

Quick Command

Quick Command is a simple, compact SMBus protocol that sends an address and 1-bit of data in the R/S bit of the I²C header byte to communicate a command to the slave, typically a "turn off" or "turn on". The I²C master peripheral has the ability to send a Quick Command by writing the target address and R/S value into the **I2CMCSA** register followed by a write to **I2CMCS** with a value of 0x27. SMBus requires the slave to be able to accept and process commands and the master to generate the Quick Command transactions. The master also has the capability to stop the transaction after acknowledgement from a slave.

The I²C slave peripheral requires special handling when a Quick Command is sent. In the case where a master sends a Quick Command with the R/S (data) bit cleared, the QCMDST bit in **I2CSCSR** is set, and the QCMDRW bit shows the data value (which in this case is 0) when the STOPRIS bit is set in **I2CSRIS** and the STOP interrupt is asserted. In this scenario, a DATARIS interrupt bit is not

set. When the master sends a Quick Command with the R/S (data) bit set, the DATARIS bit is set to notify the slave to write a data byte to **I2CSDR** in which bit 7 is set. A “dummy write” of 0xFF to the **I2CSDR** register is recommended. After the write to **I2CSDR**, the STOP interrupt is asserted and the QCMDST and QCMDRW bits are set in the **I2CSCSR** register to indicate that a quick command read occurred and the last transaction was a Quick Command. Therefore, when the slave must receive a Quick Command, it should be expecting such a command because it must write the **I2CSDR** with a specific value when R/S is set.

21.3.2 Available Speed Modes

The I²C bus can run in Standard mode (100 kbps), Fast mode (400 kbps), Fast mode plus (1 Mbps) or High-Speed mode (3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines). The selected mode should match the speed of the other I²C devices on the bus.

21.3.2.1 Standard, Fast, and Fast Plus Modes

Standard, Fast, and Fast Plus modes are selected using a value in the **I²C Master Timer Period (I2CMTPR)** register that results in an SCL frequency of 100 kbps for Standard mode, 400 kbps for Fast mode, or 1 Mbps for Fast mode plus.

The I²C clock rate is determined by the parameters *CLK_PRD*, *TIMER_PRD*, *SCL_LP*, and *SCL_HP* where:

CLK_PRD is the system clock period

SCL_LP is the low phase of SCL (fixed at 6)

SCL_HP is the high phase of SCL (fixed at 4)

TIMER_PRD is the programmed value in the **I2CMTPR** register (see page 1460). This value is determined by replacing the known variables in the equation below and solving for *TIMER_PRD*.

The I²C clock period is calculated as follows:

$$SCL_PERIOD = 2 \times (1 + TIMER_PRD) \times (SCL_LP + SCL_HP) \times CLK_PRD$$

For example:

$$CLK_PRD = 50 \text{ ns}$$

$$TIMER_PRD = 2$$

$$SCL_LP=6$$

$$SCL_HP=4$$

yields a SCL frequency of:

$$1/SCL_PERIOD = 333 \text{ KHz}$$

Table 21-2 gives examples of the timer periods that should be used to generate Standard, Fast mode, and Fast mode plus SCL frequencies based on various system clock frequencies.

Table 21-2. Examples of I²C Master Timer Period Versus Speed Mode

System Clock	Timer Period	Standard Mode	Timer Period	Fast Mode	Timer Period	Fast Mode Plus
4 MHz	0x01	100 Kbps	-	-	-	-
6 MHz	0x02	100 Kbps	-	-	-	-

Table 21-2. Examples of I²C Master Timer Period Versus Speed Mode (continued)

System Clock	Timer Period	Standard Mode	Timer Period	Fast Mode	Timer Period	Fast Mode Plus
12.5 MHz	0x06	89 Kbps	0x01	312 Kbps	-	-
16.7 MHz	0x08	93 Kbps	0x02	278 Kbps	-	-
20 MHz	0x09	100 Kbps	0x02	333 Kbps	-	-
25 MHz	0x0C	96.2 Kbps	0x03	312 Kbps	-	-
33 MHz	0x10	97.1 Kbps	0x04	330 Kbps	-	-
40 MHz	0x13	100 Kbps	0x04	400 Kbps	0x01	1000 Kbps
50 MHz	0x18	100 Kbps	0x06	357 Kbps	0x02	833 Kbps
80 MHz	0x27	100 Kbps	0x09	400 Kbps	0x03	1000 Kbps
100 MHz	0x31	100 Kbps	0x0C	385 Kbps	0x04	1000 Kbps
120 MHz	Pending	Pending	Pending	Pending	Pending	Pending

21.3.2.2 High-Speed Mode

The TM4C129XKCZAD I²C peripheral has support for High-speed operation as both a master and slave. High-Speed mode is configured by setting the HS bit in the **I²C Master Control/Status (I2CMCS)** register. High-Speed mode transmits data at a high bit rate with a 66.6%/33.3% duty cycle, but communication and arbitration are done at Standard, Fast mode, or Fast-mode plus speed, depending on which is selected by the user. When the HS bit in the **I2CMCS** register is set, current mode pull-ups are enabled.

The clock period can be selected using the equation below, but in this case, SCL_LP=2 and SCL_HP=1.

$$SCL_PERIOD = 2 \times (1 + TIMER_PRD) \times (SCL_LP + SCL_HP) \times CLK_PRD$$

So for example:

```
CLK_PRD = 25 ns
TIMER_PRD = 1
SCL_LP=2
SCL_HP=1
```

yields a SCL frequency of:

$$1/T = 3.33 \text{ Mhz}$$

Table 21-3 on page 1432 gives examples of timer period and system clock in High-Speed mode. Note that the HS bit in the **I2CMTPR** register needs to be set for the TPR value to be used in High-Speed mode.

Table 21-3. Examples of I²C Master Timer Period in High-Speed Mode

System Clock	Timer Period	Transmission Mode
40 MHz	0x01	3.33 Mbps
50 MHz	0x02	2.77 Mbps
80 MHz	0x03	3.33 Mbps

When operating as a master, the protocol is shown in Figure 21-7. The master is responsible for sending a master code byte in either Standard (100 Kbps) or Fast-mode (400 Kbps) before it begins

transferring in High-speed mode. The master code byte must contain data in the form of 0000.1XXX and is used to tell the slave devices to prepare for a High-speed transfer. The master code byte should never be acknowledged by a slave since it is only used to indicate that the upcoming data is going to be transferred at a higher data rate. To send the master code byte for a standard high-speed transfer, software should place the value of the master code byte into the **I2CMSCA** register and write the **I2CMCS** register with a value of 0x13. If a high-speed burst transfer is required, then to send the master code byte, software should place the value of the master code byte into the **I2CMSCA** register and write the **I2CMCS** register with 0x50. Either configuration places the I²C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the **HS** bit in the **I2CMCS** register. Again, setting the **HS** bit in the **I2CMCS** register is only necessary during the master code byte.

When operating as a High-speed slave, there is no additional software required.

Figure 21-7. High-Speed Data Format

Note: High-Speed mode is 3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines.

21.3.3 Interrupts

The I²C can generate interrupts when the following conditions are observed in the Master Module:

- Master transaction completed (**RIS** bit)
- Master arbitration lost (**ARBLOSTRIS** bit)
- Master Address/Data NACK (**NACKRIS** bit)
- Master bus timeout (**CLKRIS** bit)
- Next byte request (**RIS** bit)
- Stop condition on bus detected (**STOPRIS** bit)
- Start condition on bus detected (**STARTRIS** bit)
- RX DMA interrupt pending (**DMARXRIS** bit)
- TX DMA interrupt pending (**DMATXRIS** bit)
- Trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (**TXRIS** bit)
- Trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (**RXRIS** bit)

- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

Interrupts are generated when the following conditions are observed in the Slave Module:

- Slave transaction received (DATARIS bit)
- Slave transaction requested (DATARIS bit)
- Slave next byte transfer request (DATARIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Programmable trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Programmable trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)
- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

The I²C master and I²C slave modules have separate interrupt registers. Interrupts can be masked by clearing the appropriate bit in the **I2CMIMR** or **I2CSIMR** register. Note that the RIS bit in the **Master Raw Interrupt Status (I2CMRIS)** register and the DATARIS bit in the **Slave Raw Interrupt Status (I2CSRIS)** register have multiple interrupt causes including a next byte transfer request interrupt. This interrupt is generated when both master and slave are requesting a receive or transmit transaction.

21.3.4 Loopback Operation

The I²C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the LPBK bit in the **I²C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and are tied to the SDA and SCL signals of the slave module to allow internal testing of the device without having to go through I/O.

21.3.5 FIFO and μDMA Operation

Both the master and the slave module have the capability to access two 8-byte FIFOs that can be used in conjunction with the μDMA for fast transfer of data. The transmit (TX) FIFO and receive (RX) FIFO can be independently assigned to either the I²C master or I²C slave. Thus, the following FIFO assignments are allowed:

- The transmit and receive FIFOs can be assigned to the master
- The transmit and receive FIFOs can be assigned to the slave

- The transmit FIFO can be assigned to the master, while the receive FIFO is assigned to the slave and vice versa.

In most cases, both FIFOs will be assigned to either the master or the slave. The FIFO assignment is configured by programming the TXASGNMT and RXASGNMT bit in the **I²C FIFO Control (I2CFIFOCTL)** register.

Each FIFO has a programmable threshold point which indicates when the FIFO service interrupt should be generated. Additionally, a FIFO receive full and transmit empty interrupt can be enabled in the Interrupt Mask (**I2CxIMR**) registers of both the master and slave. Note that if we clear the TXFERIS interrupt (by setting the TXFEIC bit) when the TX FIFO is empty, the TXFERIS interrupt does not reassert even though the TX FIFO remains empty in this situation.

When a FIFO is not assigned to a master or a slave module, the FIFO interrupt and status signals to the module are forced to a state that indicates the FIFO is empty. For example, if the TX FIFO is assigned to the master module, the status signals to the slave transmit interface indicates that the FIFO is empty.

Note: The FIFOs must be empty when reassigning the FIFOs for proper functionality

21.3.5.1 Master Module Burst Mode

A BURST command is provided for the master module which allows a sequence of data transfers using the μDMA (or software, if desired) to handle the data in the FIFO. The BURST command is enabled by setting the BURST bit in the **Master Control/Status (I2CMCS)** register. The number of bytes transferred by a BURST request is programmed in the **I²C Master Burst Length (I2CMBLEN)** register and a copy of this value is automatically written to the **I²C Master Burst Count (I2CMBCNT)** register to be used as a down-counter during the BURST transfer. The bytes written to the **I²C FIFO Data (I2CFIFODATA)** register are transferred to the RX FIFO or TX FIFO depending on whether a transmit or receive is being executed. If data is NACKed during a BURST and the STOP bit is set in the **I2CMCS** register, the transfer terminates. If the STOP bit is not set, the software application must issue a repeated STOP or START when a NACK interrupt is asserted. In the case of a NACK, the **I2CMBCNT** register can be used to determine the amount of data that was transferred prior to the BURST termination. If the Address is NACKed during a transfer, then a STOP is issued.

Master Module μDMA Functionality

When the **Master Control/Status (I2CMCS)** register is set to enable BURST and the master I²C μDMA channel is enabled in the **DMA Channel Map Select n (DMACHMAPn)** registers in the μDMA, the master control module will assert either the internal single μDMA request signal (dma_sreq) or multiple μDMA request signal (dma_req) to the μDMA. Note that there are separate dma_req and dma_sreq signals for transmit and receive. A single μDMA request (dma_sreq) will be asserted by the Master module when the Rx FIFO has at least one data byte present in the FIFO and/or when the Tx FIFO has at least one space available to fill. The dma_req (or Burst) signal will be asserted when Rx FIFO fill level is higher than trigger level and/or the Tx FIFO burst length remaining is less than 4 bytes and the FIFO fill level is less than trigger level. If a single transfer or BURST operation has completed, the μDMA sends a dma_done signal to the master module represented by the DMATX/DMARX interrupts in the **I2CMIMR/I2CMRIS/I2CMMIS/I2CMICR** registers.

If the μDMA I²C channel is disabled and software is used to handle the BURST command, software can read the **FIFO Status (I2CFIFOSTAT)** Register and the **Master Burst Count (I2CMBC)** register to determine whether the FIFO needs servicing during the BURST transaction. A trigger value can be programmed in the **I2CFIFOCTL** register to allow for interrupts at various fill levels of the FIFOs.

The NACK and ARBLOST bits in the interrupt status registers can be enabled to indicate no acknowledgement of data transfer or an arbitration loss on the bus.

When the Master module is transmitting FIFO data, software can fill the Tx FIFO in advance of setting the BURST bit in the **I2CMCS** register. If the FIFO is empty when the µDMA is enabled for BURST mode, the `dma_req` and `dma_sreq` both assert (assuming the **I2CMBLEN** register is programmed to at least 4 bytes and the Tx FIFO fill level is less than the trigger set). If the **I2CMBLEN** register value is less than 4 and the Tx FIFO is not full but more than trigger level, only `dma_sreq` will assert. Single requests will be generated as required to keep the FIFO full until the number of bytes specified in the **I2CMBLEN** register has been transferred to the FIFO (and the **I2CMBCOUNT** register reaches 0x0). At this point, no further requests are generated until the next BURST command is issued. If the µDMA is disabled, FIFOs will be serviced based on the interrupts active in the Master interrupt status registers, the FIFO trigger values shown in the **I2CFIFOSTATUS** register and completion of a BURST transfer.

When the Master module is receiving FIFO data, the Rx FIFO is initially empty and no requests are asserted. If data is read from the slave and placed into the Rx FIFO, the `dma_sreq` signal to the µDMA is asserted to indicate there is data to be transferred. If the Rx FIFO contains at least 4 bytes, the `dma_req` signal is also asserted. The µDMA will continue to transfer data out of the Rx FIFO until it has reached the amount of bytes programmed in the **I2CMBLEN** register.

Note: The TXFEIM interrupt mask bit in the **I2CMIMR** register should be clear (masking the TXFE interrupt) when the master is performing an RX Burst from the RXFIFO and should be unmasked before starting a TX FIFO transfers.

21.3.5.2 Slave Module

The slave module also has the capability to use the µDMA in Rx and Tx FIFO data transfers. If the Tx FIFO is assigned to the slave module and the TXFIFO bit is set in the **I2CSCSR** register, the slave module will generate a single µDMA request, `dma_sreq`, if the master module requests the next byte transfer. If the FIFO fill level is less than the trigger level, a µDMA multiple transfer request, `dma_req`, will be asserted to continue data transfers from the µDMA.

If the Rx FIFO is assigned to the slave module and the RXFIFO bit is set in the **I2CSCSR** register, then the slave module will generate a signal µDMA request, `dma_sreq`, if there is any data to be transferred. The `dma_req` signal will be asserted when the Rx FIFO has more data than the trigger level programmed by the RXTRIG bit in the **I2CFIFOCTL** register.

Note: Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

21.3.6 Command Sequence Flow Charts

This section details the steps required to perform the various I²C transfer types in both master and slave mode. Refer to Table 21-5 on page 1455 for further sequence information.

21.3.6.1 I²C Master Command Sequences

The figures that follow show the command sequences available for the I²C master.

21.4 Initialization and Configuration

21.4.1 Configure the I²C Module to Transmit a Single Byte as a Master

The following example shows how to configure the I²C module to transmit a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I²C clock using the **RCGCI2C** register in the System Control module (see page 407).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 398). To find out which GPIO port to enable, refer to Table 31-5 on page 2085.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register (see page 799). To determine which GPIOs to configure, see Table 31-4 on page 2068.

4. Enable the I²CSDA pin for open-drain operation. See page 804.
5. Configure the PMC_n fields in the **GPIOPCTL** register to assign the I²C signals to the appropriate pins. See page 816 and Table 31-5 on page 2085.
6. Initialize the I²C Master by writing the **I2CMCR** register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```
TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;
TPR = (20MHz / (2 * (6+4) * 100000)) - 1;
TPR = 9
```

Write the **I2CMTPR** register with the value of 0x0000.0009.

8. Specify the slave address of the master and that the next operation is a Transmit by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
9. Place data (byte) to be transmitted in the data register by writing the **I2CMDR** register with the desired data.
10. Initiate a single byte transmit of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
11. Wait until the transmission completes by polling the **I2CMCS** register's **BUSBSY** bit until it has been cleared.
12. Check the **ERROR** bit in the **I2CMCS** register to confirm the transmit was acknowledged.

21.4.2 Configure the I²C Master to High Speed Mode

To configure the I²C master to High Speed mode:

1. Enable the I²C clock using the **RCGCI2C** register in the System Control module (see page 407).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 398). To find out which GPIO port to enable, refer to Table 31-5 on page 2085.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFCSEL** register (see page 799). To determine which GPIOs to configure, see Table 31-4 on page 2068.
4. Enable the I²CSDA pin for open-drain operation. See page 804.
5. Configure the PMC_n fields in the **GPIOPCTL** register to assign the I²C signals to the appropriate pins. See page 816 and Table 31-5 on page 2085.
6. Initialize the I²C Master by writing the **I2CMCR** register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 3.33 Mbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```
TPR = (System Clock/(2*(SCL_LP + SCL_HP)*SCL_CLK))-1;
TPR = (80 MHz/(2*(2+1)*3330000))-1;
TPR = 3
```

Write the **I2CMTPR** register with the value of 0x0000.0003.

8. To send the master code byte, software should place the value of the master code byte into the I2CMCSA register and write the I2CMCS register with the following value depending on the required operation:
 - For Standard High-Speed mode, the **I2CMCS** register should be written with 0x13.
 - For Burst High-Speed mode, the **I2CMCS** register should be written with 0x50.
9. This places the I2C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the HS bit in the **I2CMCS** register.
10. The transaction is ended by setting the STOP bit in the **I2CMCS** register.
11. Wait until the transmission completes by polling the **I2CMCS** register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the **I2CMCS** register to confirm the transmit was acknowledged.

21.5 Register Map

Table 21-4 on page 1447 lists the I²C registers. All addresses given are relative to the I²C base address:

- I²C 0: 0x4002.0000
- I²C 1: 0x4002.1000
- I²C 2: 0x4002.2000
- I²C 3: 0x4002.3000
- I²C 4: 0x400C.0000
- I²C 5: 0x400C.1000
- I²C 6: 0x400C.2000
- I²C 7: 0x400C.3000
- I²C 8: 0x400B.8000
- I²C 9: 0x400B.9000

Note that the I²C module clock must be enabled before the registers can be programmed (see page 407). There must be a delay of 3 system clocks after the I²C module clock is enabled before any I²C module registers are accessed.

The hw_i2c.h file in the TivaWare™ Driver Library uses a base address of 0x800 for the I²C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that TivaWare™ for C Series uses an offset between 0x000 and 0x018 with the slave base address.

Table 21-4. Inter-Integrated Circuit (I²C) Interface Register Map

Offset	Name	Type	Reset	Description	See page

21.6 Register Descriptions (I²C Master)

The remainder of this section lists and describes the I²C master registers, in numerical order by address offset.

Register 1: I²C Master Slave Address (I2CMSA), offset 0x000

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Transmit (Low).

I2C Master Slave Address (I2CMSA)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000
 I2C 2 base: 0x4002.2000
 I2C 3 base: 0x4002.3000
 I2C 4 base: 0x400C.0000
 I2C 5 base: 0x400C.1000
 I2C 6 base: 0x400C.2000
 I2C 7 base: 0x400C.3000
 I2C 8 base: 0x400B.8000
 I2C 9 base: 0x400B.9000
 Offset 0x000
 Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

7:1	SA	RW	0x00	I ² C Slave Address This field specifies bits A6 through A0 of the slave address.
-----	----	----	------	---

0	R/S	RW	0	Receive/Send The R/S bit specifies if the next master operation is a Receive (High) or Transmit (Low).
---	-----	----	---	---

Value	Description
0	Transmit
1	Receive

Register 2: I²C Master Control/Status (I2CMCS), offset 0x004

This register accesses status bits when read and control bits when written. When read, the status register indicates the state of the I²C bus controller. When written, the control register configures the I²C controller operation.

The START bit generates the START or REPEATED START condition. The STOP bit determines if the cycle stops at the end of the data cycle or continues to the next transfer cycle, which could be a repeated START. To generate a single transmit cycle, the **I²C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and this register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due to an error), an interrupt becomes active and the data may be read from the **I2CMDR** register. When the I²C module operates in Master receiver mode, the ACK bit is normally set, causing the I²C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I²C bus controller requires no further data to be transmitted from the slave transmitter.

Read-Only Status Register

I2C Master Control/Status (I2CMCS)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000

See field decoding in Table 21-5 on page 1455.
Value	Description									
0	The controller does not generate the START condition.									
1	The controller generates the START or repeated START condition. See field decoding in Table 21-5 on page 1455.									

Bit/Field	Name	Type	Reset	Description
0	RUN	WO	0	I^2C Master Enable
Value Description				
0 In standard and high speed mode, this encoding means the master is unable to transmit or receive data. In Burst mode, this bit is not used and must be set to 0.				
1 The master is able to transmit or receive data. Note that this bit cannot be set in Burst mode. See field decoding in Table 21-5 on page 1455.				

Note that the BURST and RUN bits are mutually exclusive.

The Table 21-5 on page 1455 can be read from left to right to determine the next state after programming bits in the **I2CMSCA** and **I2CMCS** registers.

Table 21-5. Write Field Decoding for I2CMCS[6:0]

Current State	I2CMSA[0]		I2CMCS[6:0]						Next State Description
	R/S	BURST	QCCMD	HS	ACK	STOP	START	RUN	
Idle	0	0	0	0	x ^a	0	1	1	START condition followed by TRANSMIT (master goes to the Master Transmit state).
	0	0	0	0	X	1	1	1	START condition followed by a TRANSMIT and STOP condition (master remains in Idle state).
	0	1	0	0	X	0	1	0	START condition followed by N FIFO-serviced TRANSMITs (master goes to the Master Transmit state).
	0	1	0	0	X	1	1	0	START condition followed by N FIFO-serviced TRANSMITs and STOP condition (master remains in Idle state).
	1	0	0	0	0	0	1	1	START condition followed by RECEIVE operation with negative ACK (master goes to the Master Receive state).
	0	0	1	0	0	1	1	1	Quick Command (Send). After Quick Command is executed, the master returns to Idle state.
	1	0	1	0	0	1	1	1	Quick Command (Receive). After Quick Command is executed, the master returns to Idle state.
	1	0	0	0	0	1	1	1	START condition followed by RECEIVE and STOP condition (master remains in Idle state).
	1	0	0	0	1	0	1	1	START condition followed by RECEIVE (master goes to the Master Receive state).

	1	0	0	0	0	1	1	1	Repeated START condition followed by a RECEIVE and STOP condition (master goes to Idle state).	
	1	0	0	0	1	0	1	1	Repeated START condition followed by RECEIVE (master goes to Master Receive state).	
	1	1	0	0	0	0	1	0	Repeated START condition followed by N FIFO-serviced RECEIVE operations with a negative ACK on the last RECEIVE operation (master goes to Master Receive state).	
	1	1	0	0	0	1	1	0	Repeated START condition followed by N FIFO-serviced RECEIVE operations and STOP condition (master goes to Idle state).	
	1	1	0	0	1	0	1	0	Repeated START condition followed by N FIFO-serviced RECEIVE operations (master goes to Master Receive state).	
	1	0	0	0	1	1	1	1	Illegal.	
	1	1	0	0	1	1	1	0	Illegal.	
	All other combinations not listed are non-operations.								NOP.	

Table 21-5. Write Field Decoding for I2CMCS[6:0] (continued)

Current State	I2CMSA[0]		I2CMCS[6:0]						Next State Description
	R/S	BURST	QCCMD	HS	ACK	STOP	START	RUN	
Master Receive	X	0	0	0	0	0	0	1	RECEIVE operation with negative ACK (master remains in Master Receive state).
	X	0	0	0	X	1	0	0	STOP condition (master goes to Idle state). ^b
	X	0	0	0	0	1	0	1	RECEIVE followed by STOP condition (master goes to Idle state).
	X	0	0	0	1	0	0	1	RECEIVE operation (master remains in Master Receive state).
	X	1	0	0	0	0	0	0	N FIFO-serviced RECEIVE operations with negative ACK on the last RECEIVE (master remains in Master Receive state).
	X	1	0	0	0	1	0	0	N FIFO-serviced RECEIVE operations followed by STOP condition (master goes to Idle state).
	X	1	0	0	1	0	0	0	N FIFO-serviced RECEIVE operations (master remains in Master Receive state).
	X	0	0	0	1	1	0	1	Illegal.
	X	1	0	0	1	1	0	0	Illegal.
	1	0	0	0	0	0	1	1	Repeated START condition followed by RECEIVE operation with a negative ACK (master remains in Master Receive state).
	1	0	0	0	0	1	1	1	Repeated START condition followed by RECEIVE and STOP condition (master goes to Idle state).
	1	0	0	0	1	0	1	1	Repeated START condition followed by RECEIVE (master remains in Master Receive state).
	1	1	0	0	0	0	1	0	Repeated START condition followed by N FIFO-serviced RECEIVE operations with a negative ACK on the last RECEIVE (master remains in Master Receive state).
	1	1	0	0	0	1	1	0	Repeated START condition followed by N FIFO-serviced RECEIVE operations and STOP condition (master goes to Idle state).
	1	1	0	0	1	0	1	0	Repeated START condition followed by N FIFO-serviced RECEIVE operations (master remains in Master Receive state).
	0	0	0	0	X	0	1	1	Repeated START condition followed by TRANSMIT (master goes to Master Transmit state).
	0	0	0	0	X	1	1	1	Repeated START condition followed by TRANSMIT and STOP condition (master goes to Idle state).
	0	1	0	0	X	0	1	0	Repeated START condition followed by N FIFO-serviced TRANSMIT operations (master goes to Master Transmit state).
	0	1	0	0	X	1	1	0	Repeated START condition followed by N FIFO-serviced TRANSMIT operations and STOP condition (master goes to Idle state).
All other combinations not listed are non-operations.								NOP.	

a. An X in a table cell indicates the bit can be 0 or 1.

- b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

Register 3: I²C Master Data (I2CMDR), offset 0x008

Important: This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Master Transmit state and the data received when in the Master Receive state. If the BURST bit is enabled in the **I2CMCS** register, then the **I2CFIFODATA** register is used for the current data transmit or receive value and this register is ignored.

I2C Master Data (I2CMDR)

I2C 0 base: 0x4002.0000

			1	Master mode is enabled.
3:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	LPBK	RW	0	I ² C Loopback
				Value Description
			0	Normal operation.
			1	The controller in a test mode loopback configuration.

Register 10: I²C Master Clock Low Timeout Count (I2CMCLKOCNT), offset 0x024

This register contains the upper 8 bits of a 12-bit counter that can be used to keep the timeout limit for clock stretching by a remote slave. The lower four bits of the counter are not user visible and are always 0x0.

Note: The Master Clock Low Timeout counter counts for the entire time SCL is held Low continuously. If SCL is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the I2CMCLKOCNT register and begins counting down from this value.

I2C Master Clock Low Timeout Count (I2CMCLKOCNT)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

I2C 8 base: 0x400B.8000

I2C 9 base: 0x400B.9000

Offset 0x030

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CNTL	RW	0	I ² C Burst Length This field contains the programmed length of bytes of the Burst Transaction. If BURST is enabled this register must be set to a non-zero value otherwise an error will occur.

Register 13: I²C Master Burst Count (I2CMBCNT), offset 0x034

When BURST is active, the value in the I2CMBLEN register is copied into this register and decremented during the BURST transaction. This register can be used to determine the number of transfers that occurred when a BURST terminates early (as a result of a data NACK). When a BURST completes successfully, this register will contain 0.

I2C Master Burst Count (I2CMBCNT)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

I2C 2 base: 0x4002.2000

Offset 0x034

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CNTL	RO	0	I ² C Master Burst Count This field contains the current count-down value of the BURST transaction.

21.7 Register Descriptions (I²C Slave)

The remainder of this section lists and describes the I²C slave registers, in numerical order by address offset.

Register 14: I²C Slave Own Address (I2CSOAR), offset 0x800

This register consists of seven address bits that identify the TM4C129XKCZAD I²C device on the I²C bus.

I²C Slave Own Address (I2CSOAR)

I²C 0 base: 0x4002.0000
 I²C 1 base: 0x4002.1000
 I²C 2 base: 0x4002.2000
 I²C 3 base: 0x4002.3000
 I²C 4 base: 0x400C.0000

				Once this bit has been set, it should not be set again unless it has been cleared by writing a 0 or by a reset, otherwise transfer failures may occur.

Register 16: I²C Slave Data (I2CSDR), offset 0x808

Important: This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Slave Transmit state, and the data received when in the Slave Receive state. If the RXFIFO bit or TXFIFO bit are enabled in the **I2CSCSR** register, then this register is ignored and the data value being transferred from the FIFO is contained in the **I2CFIFODATA** register.

Note: Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

I2C Slave Data (I2CSDR)

I2C 0 base: 0x4002.0000

I2C 1 base: 0x4002.1000

I2C 2 base: 0x4002.2000

Register 21: I²C Slave Own Address 2 (I2CSOAR2), offset 0x81C

This register consists of seven address bits that identify the alternate address for the I²C device on the I²C bus.

I2C Slave Own Address 2 (I2CSOAR2)

I2C 0 base: 0x4002.0000
 I2C 1 base: 0x4002.1000
 I2C 2 base: 0x4002.2000
 I2C 3 base: 0x4002.3000
 I2C 4 base: 0x400C.0000
 I2C 5 base: 0x400C.1000
 I2C 6 base: 0x400C.2000
 I2C 7 base: 0x400C.3000
 I2C 8 base: 0x400B.8000
 I2C 9 base: 0x400B.9000
 Offset 0x81C
 Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	OAR2EN	RW	0	I ² C Slave Own Address 2 Enable
		Value	Description	
	0	The alternate address is disabled.		
	1	Enables the use of the alternate address in the OAR2 field.		
6:0	OAR2	RW	0x00	I ² C Slave Own Address 2 This field specifies the alternate OAR2 address.

Register 22: I²C Slave ACK Control (I2CSACKCTL), offset 0x820

This register enables the I²C slave to NACK for invalid data or command or ACK for valid data or command. The I²C clock is pulled low after the last data bit until this register is written.

I²C Slave ACK Control (I2CSACKCTL)

I²C 0 base: 0x4002.0000
 I²C 1 base: 0x4002.1000
 I²C 2 base: 0x4002.2000
 I²C 3 base: 0x4002.3000

 Offset 0x820
 Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	ACKOVAL	RW	0	I ² C Slave ACK Override Value
		Value	Description	
		0	An ACK is sent indicating valid data or command.	
		1	A NACK is sent indicating invalid data or command.	
0	ACKOEN	RW	0	I ² C Slave ACK Override Enable
		Value	Description	
		0	A response is not provided.	
		1	An ACK or NACK is sent according to the value written to the ACKOVAL bit.	

21.8 Register Descriptions (I²C Status and Control)

The remainder of this section lists and describes the I²C status and control registers, in numerical order by address offset.

Register 23: I²C FIFO Data (I2CFIFODATA), offset 0xF00

The I²C FIFO Data (I2CFIFODATA) register contains the current value of the top of the RX or TX FIFO stack being used in the a transfer.

Read-Only Status Register

I²C FIFO Data (I2CFIFODATA)

I²C 0 base: 0x4002.0000

I²C 1 base: 0x4002.1000

I²C 2 base: 0x4002.2000

I²C 3 base: 0x4002.3000

I²C 4 base: 0x400C.0000

I²C 5 base: 0x400C.1000

I²C 6 base: 0x400C.2000

I²C 7 base: 0x400C.3000

I²C 8 base: 0x400B.8000

I²C 9 base: 0x400B.9000

Offset 0xF00

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description

22 1-Wire Master Module

The 1-Wire Master module is a bi-directional serial communication interface that implements the protocol functions of the Dallas Semiconductor 1-Wire protocol and provides both power and data over a single wire. The 1-Wire Master module can interface with a multiple variety of slaves such as thermometers, mixed-signal devices, memory, and authentication devices.

The TM4C129XKCZAD microcontroller includes a 1-Wire Master module with the following features:

- Support for standard and overdrive speeds, including a late-sample mechanism
- Allows transfers of send, receive and bi-directional bits
- Data size transfers of 1, 2, 3, or 4 bytes with sub-byte search and enumeration support
- Interrupt capability for transaction pacing and line error
- Optional two-wire support for isolated lines and high voltage use
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)

22.1 Block Diagram

Figure 22-1 on page 1503 details the components of the 1-wire Master Module. The clock source for the 1-Wire Master module is the 16-MHz precision internal oscillator (PIOSC).

Figure 22-1. 1-Wire Block Diagram

22.2 Signal Description

The following table lists the external signals of the 1-Wire module and describes the function of each. The 1-Wire module signals are alternate functions for GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placements for the 1-Wire signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the 1-Wire function. The number in parentheses is the encoding that must be programmed into the PMC_n field in the **GPIO Port Control (GPIOCTL)** register to assign the 1-Wire signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769.

Table 22-1. 1-Wire Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
OWALT	K15 B12	PG5 (5) PP5 (4)	I/O	TTL	1-Wire Optional 2nd signal to be used as output.
OWIRE	G2 K17 V12 U14 D8 A8	PE3 (5) PG4 (5) PG6 (5) PG7 (5) PP4 (4) PP7 (5)	I/O	TTL	1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled.

22.3 Functional Description

1-Wire is a simple single-wire communication interface comprising a wire protocol, transport protocol, and base session protocols (as well as some basic commands). The wire protocol generates 0s and 1s by varying the time the line is held low (it is pulled up by a resistor). The TM4C129XKCZAD microcontroller is the master and controls the line at all times. A pull-up keeps the line parked high and the microcontroller driver is assumed to be normal open-drain. No special GPIO configuration is needed here since the open-drain support is taken care of outside of the microcontroller. See Table 10-4 on page 783 for pin configuration information. Data can be both read and written on the same 1-Wire pin. The 1-Wire module supports the most basic aspects of the protocol, including wire protocol, byte transport control and line reset. Software is expected to handle the session protocol, including selection of a slave (when more than one is on the same line) and higher level commands.

Note: All time values by the 1-Wire Master are stated in μ s, but the actual time on the wire may be less by 62.5 ns.

22.3.1 1-Wire Protocol

The 1-Wire protocol signals 1s and 0s by holding the line low for varying lengths of time as described below. For details on the operation of this device, see "Overdrive" on page 1508 Before a command is sent, a reset is issued on the line. This is a two-part operation:

- The 1-Wire Master module drives and holds line low for >480 μ s.
- The controller waits for an answer-to-reset from one or more slaves. A slave signals a reset by pulling the line low for 60 μ s to 240 μ s. If the line is not sampled low, there is no slave on the bus and the NOATR bit is set in the **1-Wire Control and Status (ONEWIRECS)** register. An interrupt mask can also be set to trigger an interrupt on this condition. If the line is sampled low, it indicates there are one or more slaves on the 1-Wire bus. The Master samples the line some period after releasing the line, taking into consideration the time needed for the slave to respond. The time from reset release to first sample is programmed through the ATRSAM bit in the **1-Wire**

Timing Override (ONEWIRETIM) register. For example, the Master could sample 10 µs after releasing the reset for 240 µs. Caution should be exercised to make sure the line has been pulled high (by a pull-up) before the Master samples to avert a bogus answer-to-reset. Because the slave may hold the line low for a longer duration than the sample time, the Master must wait for the line to go high before starting a new command. This reset protocol is used to ensure that all slaves are in a known state.

Figure 22-2 on page 1505 shows the details of the 1-wire reset.

Figure 22-2. 1-Wire Reset Protocol

If the Master is transmitting data to the slave, the signalling is as follows:

- A 1 is signaled by the master driving and holding the line low for <15 µs. Generally, about 6 µs is used for normal mode. The slave samples and measures the signal from falling edge and checks the line 15 µs later (or more). If line has reverted to high, the slave registers a 1 value.
- A 0 is signaled by the Master driving and holding the line low for 60 µs or more. Although the slave reads just past 15 µs, the normal mode requires the line to be low for 60 µs. If the line is still low after 15 µs, a value of 0 is registered.

Figure 22-3 on page 1506 depicts a 1-Wire Master transmitting a 1 to a slave. Figure 22-4 on page 1506 shows a 1-wire Master transmitting a 0 to a slave.

Figure 22-3. 1-Wire Master Transmitting a 1**Figure 22-4. 1-Wire Master Transmitting a 0'**

For a read from the slave, the Master drives and holds the line low for at least 1μs (but less than 15 μs) and then releases. A typical hold time is 6 μs; in other words, it uses a transmitted 1. The read is performed as:

- A 1 is signaled by the slave when "does nothing." Thus, the slave just allows the line to come back up when the master releases it. The master samples the line at 15μs after the low edge and the line is still high, signaling a 1.
- If the slave holds the line down for more than 5 μs (and no more than 60 μs), a 0 is signaled. The master samples the line at 15 μs after the low edge, and because the line is low still, it is treated as a 0.

Figure 22-5 on page 1507 depicts a Master receiving a 1 value from a slave. Figure 22-6 on page 1507 shows the slave sending a 0 value to a Master.

Figure 22-5. 1-Wire Master Receiving a 1 Signal from a Slave**Figure 22-6. 1-Wire Master Receiving a 0 Signal from a Slave**

22.3.2 Transport Protocol

The transport level protocol follows a simple model, in part based on treating most 1-wire devices as memory like (IDs, ROM, EEPROM, etc) even if some are sensors or actuators. All commands and data are in 8-bit (byte) quantities and the post-reset commands are pre-defined. The basic protocol is:

- Reset the line by driving and holding the OWIRE signal low for >480 µs.
- Wait for answer-to-reset from one or more slaves. Answer-to-reset (ATR) is defined as each slave pulling the line low for 60 µs to 240 µs. If the line does not go low, there is no slave on the bus. If it does, there is one or more.
- At this point the Master either figures out the ID of the slaves on the bus using the enumeration scheme, or selects a slave to issue a command. The "select" command to use is based on

whether there is one slave or more than one. If there is only one slave device, the Master skips the selection process. If more than one are present, the Master selects a slave by sending out the ID for the selected slave, indicating to the remaining slaves that any further commands should be ignored until after the next reset.

- The Master sends a command followed by a sending or receiving of data. While most commands are implemented using bytes read or written, some commands use bytes where some bits are written and some read. Since a read looks like a write 1, if the line is held and driven low for less than 15 µs and the slave does not know it is supposed to reply, the line remains untouched and is read as a 1 (and written as a 1).
- Usually at the end of one or more commands to that slave, a reset is issued again.

The 1-Wire module supports reset and answer-to-reset on request (although answer-to-reset can be suppressed). It also supports byte operations. The software chooses which read, write, or mixed operation to use. Partial byte (bit or multi-bit) is also supported.

22.3.3 Overdrive

The 1-Wire Module also allows for an "overdrive" speed to be selected for shorter line lengths. Overdrive is about ten times faster because it uses smaller time periods. It is agreed by both master and slave before enabling. Overdrive is selected using the ODRV bit of the **1-Wire Control and Status (ONEWIRECS)** register.

In overdrive mode, the time periods shrink. Table 22-2 on page 1508 shows the active time for 1-Wire operations in overdrive mode. For example, the Master typically drives and holds the line low for 15 µs for a write 1, but in overdrive mode this is 1 µs.

Table 22-2. Active Time Periods in Overdrive Mode

Operation	Time	Notes
Write 1	1 µs low	Less than 2 µs low
Write 0	7.5 µs low	Up to 10 µs low
Read 1	1 µs low	Master samples at 2 µs
Read 0	9 µs low	Slave holds at least 7 µs
Reset	70 µs low	Note 2 µs delay before reset for safety
Answer to Reset	4 µs to 48 µs	Master samples at 8.5 µs

22.3.4 Timing Override

The 1-Wire module can manually override timing for any main action. Each non-zero value in the **1-Wire Timing Override (ONEWIRETIM)** register replaces the default normal or overdrive time rule.

The time factors that can be controlled:

Table 22-3. Bit Field Definitions for 1-Wire Timing and Override (ONEWIRETIM) Register

Name	Meaning	Range (if used)	Scale	Default (normal)	Default (overdrive)
W1TIM	Amount of time to drive and hold line low for a write 1	1 to 15 µs	1 µs units	6 µs	1 µs
W0TIM	Amount of time to drive and hold line low for write 0 ^a	4 to 124 µs	4 µs units	60 µs	7.5 µs

**Table 22-3. Bit Field Definitions for 1-Wire Timing and Override (ONEWIRETIM) Register
(continued)**

Name	Meaning	Range (if used)	Scale	Default (normal)	Default (overdrive)
W0REST	Amount of time to hold line high after a write 0 (rest) ^a	1 to 15 µs	1 µs units	10 µs	2.5 µs
W1SAM	Amount of time after 1-Wire has released the line to sample slave holding line	1 to 15 µs	1 µs units	10 µs	1 µs
RSTTIM	Amount of time to drive and hold line low for a reset. Allow for an additional 2-µs pre-reset period	32 to 2016 µs	32 µs units	480 µs	70 µs
ATRTIM	Period of answer-to-reset or rest. The ATRSAM bit value must be considered when programming this field. ATRTIM must be greater than ATRSAM to avoid a STUCK fault generation	16 to 496 µs	16 µs units	240 µs	48 µs
ATRSAM	Period in which first sample occurs in answer-to-reset (after line goes high). If the SKATR bit is set in the ONEWIRECS register, this value indicates the rest period after reset	8 to 120 µs	8 µs units	10 µs ^b	2 µs

a. If WOTIM has been programmed to a non-default value, WOREST must be programmed for correct functionality.

b. ATRSAM is the first sample. If the line is high, it continues sampling for the rest of ATRTIM period to see if goes low. This subsequent sampling is every 62.5 ns. Thus, this value must be long enough to be sure the line has floated high, but does not have to be after the time the slaves have driven low. This rule is different than a single sample model, which can be too late or miss on long lines.

22.3.5 Command Protocol

The standard 1-Wire protocol has commands to be used after a reset. These commands normally include slave selection and detection. However, many 1-Wire buses only have one slave, and in that case, those mechanisms can be skipped. If slave management is needed, a small software stack can be used to handle these operations. Other protocols can also be easily supported, whether byte-oriented (as normal) or bit-oriented. To support an alternative protocol, it is usually necessary to override some or all of the timing and may be necessary to disable the answer-to-reset mechanism using the SKATR bit in the **ONEWIRECS** register. The module is designed to support the most common uses of 1-Wire, including a mechanism to allow a reset followed by an operation of 1, 2, 3, or 4 bytes through the SZ bit in the **ONEWIRECS** register. Additionally, the OP bit supports a write/read model to allow a mix of write and read in one transaction. Although nominally mixed mode allows for a mix of write and read bytes, it can be used down to the bit level.

The following represents some typical operation flows:

1. To only send a reset, the RST bit of the **ONEWIRECS** register is set, performing a reset and triggering an interrupt if enabled. If there is no answer-to-reset, the NOATR status bit is set and the corresponding interrupt bit can be set as well.
2. The SZ and OP fields of the **ONEWIRECS** register are used to perform a write, a read, or a combination. For small transactions, the SZ encoding can be programmed for processing of up to 4 bytes in one transaction. For larger transactions, the OP field can be used multiple times. The OPC raw interrupt bit is used to notify when a transaction is complete.
3. To perform a reset and then a transaction, both the RST and OP/SZ fields of the **ONEWIRECS** register are configured. The reset runs to completion and then the transaction starts. The interrupt is used to notify when both are done.

To setup a read, write or mixed transaction, the following configuration needs to occur:

- For writes, the **1-Wire Data Write (ONEWIREDATW)** register must first be written with one, two, three or four bytes to send (as a word). Next the **ONEWIRECS** register is configured as described above.
- For reads, the **ONEWIRECS** register is written as described above. Then, when the transaction is complete, the **1-Wire Data Read (ONEWIREDATR)** register is read to collect the one, two, three or four bytes that were received (as a word).
- For write/read combination, the **ONEWIREDATW** register is written with one, two, three or four bytes to write or read. Then, the **ONEWIRECS** register is configured as described above. As the data is transferred from the **ONEWIREDATW** register to the 1-Wire line, any 1 that is transmitted creates a read that is registered in the **ONEWIREDATR** register. When the entire transaction is complete, the **ONEWIREDATR** register can be read to collect the bytes that were received by the 1-Wire Master. A **ONEWIREDATR** register bit contains a 0 for any bit that was written as a 0, a 1 for any bit that was written as a 1 or any bit not modified by the slave (may have been intentional 1 or ignored) and a 0 for any bit written as a 1 but read back as a '0.'

22.3.6 Search (Enumeration) and Sub-Byte

Although 1-Wire is a byte protocol, there are times when less than a byte must to be written or read. By programming the **BSIZE** field of the **ONEWIRECS** register, the number of bits to write and or read in the last byte can be configured. The **BSIZE** field can be used for a 1-Wire search (enumeration) to allow detect and select processing. Enumeration begins by executing the standard SEARCH (0xF0) command (and if available, the ALARM SEARCH (0xEC)) and then reading two bits for the ID, which is the first bit and its complement. Subsequently, a bit is emitted to select devices with that first matching bit followed by another read of two bits. This process is repeated for up to all 64 bits. To start over, a reset is used. In this way, a tree of IDs can be broken down until one unique ID is left. This can be repeated for each device. The **BSIZE** field can also be used for non-standard devices which do not fully follow protocol.

22.3.7 Interrupts

The interrupt model for the 1-Wire module allows interrupt service routines to drive continuations of operations, whether reading the results or processing more bytes. Most command sequences are small, so the module supports transactions of one, two, three, and four bytes at once. Because most commands start with a line reset, the operational model allows for a reset followed by the transaction, with an interrupt occurring when the transaction is complete. There is also support for enabling interrupts for reset complete (RST), no answer-to-reset (NOATR) and line-hold-low error detected (STUCK) in the **1-Wire Interrupt Mask (ONEWIREIM)** register.

22.3.8 DMA

The μDMA model is designed to support both normal μDMA operation on write or read, as well as scatter-gather operation. The normal mode of operation allows for continued writes of byte, half-word, or word (three-byte size is not supported by μDMA for repeated operation) as well as continued reads by byte, half-word, or word. Additionally, the first transaction may be started with a reset.

The **1-Wire DMA Control (ONEWIREDMA)** register is used to configure the μDMA. To use μDMA with 1-Wire transmits:

1. Select 1-Wire to use μDMA by programming the **DMA Channel Map Select n (DMACHMAPn)** register in the μDMA. See "Channel Assignments" on page 707 for more information.

2. Configure the µDMA to transfer bytes, half-words, or words from memory to the 1-Wire **ONEWIREDATW** register or from the **ONEWIREDATR** register through the **DMA Channel Control Word (DMACHCTL)** register (see page 732).
3. Set the **sz** field of the **ONEWIRECS** register to byte, half-word, or word (0, 1, or 3). This is the only field programmed in the **ONEWIRECS** register.
4. Enable the DMA completion interrupt in the **ONEWIREIM** register. It is also recommended that the **ERR** and **NOATR** interrupts should be enabled when using the µDMA to ensure that the application is notified if the reset or transaction failed.
5. Write the **DMAOP** field of the **ONEWIREDMA** register with the encoding 0x2 to enable the 1-Wire module assert a µDMA request when **ONEWIREDATW** is empty. The **RST** bit in the **ONEWIREDMA** register can be set for reset to be asserted first before requesting a µDMA access.
6. When the µDMA transfer is complete, the **DMA** bit in the **1-Wire Raw Interrupt Status (ONEWIRERIS)** register is set and the **ONEWIREDMA** register is cleared.

A 1-Wire µDMA receive configuration is as follows:

1. Select 1-Wire to use µDMA by programming the **DMA Channel Map Select n (DMACHMAPn)** register in the µDMA. See “Channel Assignments” on page 707 for more information.
2. Configure the µDMA to transfer bytes, half-words, or words from the 1-Wire **ONEWIREDATR** register through the **DMA Channel Control Word (DMACHCTL)** register (see page 732).
3. Enable the DMA completion interrupt in the **ONEWIREIM** register. It is also recommended that the **ERR** and **NOATR** interrupts should be enabled when using the µDMA to ensure that the application is notified if the reset or transaction failed.
4. Write the **DMAOP** field of the **ONEWIREDMA** register with the encoding 0x1 or 0x3 to enable a read or read multiple by the µDMA. The **RST** bit in the **ONEWIREDMA** register can be set for reset to be asserted first before requesting a µDMA access.
5. Write the **ONEWIREDATW** register with 0xFFFF.FFFF to prime the read operations. If the **RST** bit is not set in the **ONEWIREDMA** register, the transaction begins. If **RST** was set, the read starts when reset is complete. At the end of the read operation, the µDMA receives a request to transfer the data from the **ONEWIREDATR** register. If the **DMAOP** bit was configured for a multiple read (0x3), then the next read transaction will automatically start. If not, then no further µDMA requests occur unless **ONEWIREDATR** is written to.
6. When a µDMA receive is complete, the **DMA** bit in the **1-Wire Raw Interrupt Status (ONEWIRERIS)** register is set and the **ONEWIREDMA** register is cleared.

The normal flow for writing/reading in one operation is:

1. Configure the **DMAOP** bit in the **ONEWIREDMA** register for a read, and optionally set the **RST** bit. If **RST** is selected, the reset is performed first, else the module waits for the next step.
2. Write the **ONEWIREDATW** register with one, two, or four bytes containing the mix of writes and reads. For example, to write 0x46, 0x20, and then read 2 bytes, set size to word (**sz=3**) and write **ONEWIREDATW** with 0xFFFF2046 to send the 0x46 and 0x20 and then read the last two bytes. On completion, the **ONEWIREDATR** contains the read values in the upper two bytes. If

`RST` is not set in the **ONEWIREDMA** register, the transaction starts. If `RST` is set, the transaction starts when reset completes. At the end of the operation, the µDMA is requested to transfer the data from the **ONEWIREDATR** register (read).

3. When the µDMA is done, the `DMA` bit in the **ONEWIRERIS** register is set, allowing interrupt on completion by µDMA, and the **ONEWIREDMA** register is cleared.

It is recommended to enable trigger interrupts for `ERR` and `NOATR` when using µDMA so application is notified if reset or the transaction failed.

The natural model for using scatter-gather is:

1. Enable peripheral-scatter-gather in the µDMA module by programming the **DMA Channel Control Word (DMACHCTL)** register.
2. Set the `DMAOP` to read (not read multiple) and enable scatter gather in the 1-Wire module by setting the `SG` bit to `0x1` in the **ONEWIREDMA** register. This allows use of **ONEWDATW** register to push through transactions, with µDMA request being triggered off completion, except for the first transaction.
3. Scatter gather can then use a combination of write and read as needed.

22.3.9 1-Wire Timing

The 1-Wire module wire control operates using the Precision Internal Oscillator (PIOSC) to provide a reliable frequency with no need for baud dividers. The register interface operates using the system clock, which may be a different clock source. However, there is no visible impact from this separate clock model. Normal rules apply to use of the registers to ensure correct operation. In particular:

- The control register is used live (not buffered) by the communication engine. Once an operation is started, it must be allowed to finish before changes are made, such as starting a new operation or changing speed. The status bits in the **ONEWIRECS** register notify the application if the transaction is busy or if a line-hold-low error is detected. When the last write, read or read/write has occurred, the `OPC` bit is set in the **ONEWIRERIS** register.
- Data read by the 1-Wire Master is not valid or meaningful until the 1-Wire module signals that the data is ready (via interrupt, DMA, and status).
- Data written should be written before the operation is started and then should not be re-written until the 1-Wire module signals the data has been written (via interrupt, DMA, and status).
- The **1-Wire Timing Override (ONEWIRETIM)** register should not be changed while a transaction is taking place.

The **ONEWIREIM**, **ONEWIRERIS** and **ONEWIREMIS** registers may be written and read at any time with no risk.

22.4 Initialization and Configuration

The whole block may be enabled or disabled using the system control registers. The following example shows how to enable, force a reset and send a command.

1. Enable the 1-Wire Module by writing a value of `0x0000.0001` to the **1-Wire Run Mode Clock Gating Control (RCGCOWIRE)** register in the System Control Module, see page 419.

2. Enable the clock to the appropriate GPIO port that is used for the 1-Wire signals using the **General-Purpose Input/Output Run Mode Clock gating Control (RCGCGPIO)** in the System Control Module; see page 398. To find out which GPIO port to enable, refer to Table 31-5 on page 2085.
3. In the GPIO module, enable the appropriate pin for its alternate function using the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 799).
4. Configure the `PMCn` fields in the **GPIOPCTL** register to assign the 1-Wire signals to the appropriate pins. See page 816 and Table 31-5 on page 2085.
5. Optionally enable interrupts to be notified when the transactions completes.
6. Write to the **ONEWIREDATW** register with the data to write (1, 2, 3, or 4 bytes).
7. Write to the **ONEWIRECS** register to set the `RST` bit and configure the `OP` (operation) and `SZ` fields. When configuring all three bit fields, the reset is performed first, followed by the operation (unless an error occurs) and then any interrupt triggers.
8. If normal interrupts are generated (for example, `OPC` and `RST`), clear these interrupts and read the **ONEWIREDATR** register if a read or read/write transaction occurred.
9. If the 1-Wire master has more data to write and/or read for the same command, repeat the previous two steps but without setting the `RST` bit. If a new command is required, repeat the previous two steps including the reset enable.

22.5 Register Map

Table 22-4 on page 1513 lists the 1-Wire Master Module registers. The offset listed is a hexadecimal increment to the register's address, relative to the 1-Wire Master module's base address 0x400B.6000.

Table 22-4. OWIRE Register Map

Offset	Name	Type	Reset	Description	See page
0x000	ONEWIRECS	RW	0x0000.0000	1-Wire Control and Status	1515
0x004	ONEWIREDATIM	RW	0x0000.0000	1-Wire Timing Override	1519
0x008	ONEWIREDATW	RW	0x0000.0000	1-Wire Data Write	1520
0x00C	ONEWIREDATR	RW	0x0000.0000	1-Wire Data Read	1521
0x100	ONEWIREIM	RW	0x0000.0000	1-Wire Interrupt Mask	1522
0x104	ONEWIRERIS	RO	0x0000.0000	1-Wire Raw Interrupt Status	1524
0x108	ONEWIREMIS	RO	0x0000.0000	1-Wire Masked Interrupt Status	1526
0x10C	ONEWIREICR	RW1C	0x0000.0000	1-Wire Interrupt Clear	1528
0x120	ONEWIREDMA	RW	0x0000.0000	1-Wire µDMA Control	1529
0xFC0	ONEWIREPP	RO	0x0000.0011	1-Wire Peripheral Properties	1531

22.6 1-Wire Master Register Descriptions

This section lists and describes the 1-Wire Master Module registers, in numerical order by address offset.

Register 1: 1-Wire Control and Status (ONEWIRECS), offset 0x000

The **1-Wire Control and Status (ONEWIRECS)** register contains the control and status bits for the 1-Wire bus, including active state and passive detection. The **OP** field is written to start an operation. If executing a write or a write/read, the **Bn** field of the **1-Wire Data Write (ONEWIREDATW)** register must be written first before programming the **OP** field.

1-Wire Control and Status (ONEWIRECS)

Base 0x400B.6000
Offset 0x000
Type RW, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value	Description													
0x0	No operation													
0x1	Read													
0x2	Write													
0x3	Write/Read													
0	RST	RW	0	<p>Reset Request</p> <p>If RST = 1, a reset operation begins. This bit clears when the reset operation is complete and the NOATR bit can be read to verify that a slave responded.</p> <p>If this bit is set at the same time as the OP bit is set, the reset runs first and the operation starts when reset has completed. If this bit is written when an operation is already in progress, it cancels the operation and starts the reset.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No effect.</td></tr> <tr> <td>1</td><td>Reset operation request.</td></tr> </tbody> </table>	Value	Description	0	No effect.	1	Reset operation request.				
Value	Description													
0	No effect.													
1	Reset operation request.													

Register 2: 1-Wire Timing Override (ONEWIRETIM), offset 0x004

The **1-Wire Timing Override (ONEWIRETIM)** register allows for overriding of the timing rules for the 1-Wire interface. If a field is 0, the default is used (normal or overdrive).

1-Wire Timing Override (ONEWIRETIM)

Base 0x400B.6000
Offset 0x004
Type RW, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Type	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W1SAM	ATRSAM				ATRTIM				RSTTIM							

Bit/Field	Name	Type	Reset	Description
31:28	W1TIM	RW	0	Value 1 Timing This field indicates the time low for a 1 in μ s units.
27:23	W0TIM	RW	0	Value 0 Timing Indicates time low for a 0 in 4 μ s units. Note: If W0TIM has been programmed to a non-default value, W0REST must be programmed for correct functionality.
22:19	W0REST	RW	0	Rest Time This field indicates time to rest after a 0 in 1 μ s units. Note: If W0TIM has been programmed to a non-default value, W0REST must be programmed for correct functionality.
18:15	W1SAM	RW	0	Sample Time Time to sample for a 1 vs 0 in μ s after the release of the line by 1-Wire. The LSAM bit is ignored if this bit is set.
14:11	ATRSAM	RW	0	Answer-to-Reset Sample Time to first sample for answer-to-reset in 8 μ s units. Sampling continues until time indicated by ATRTIM bit. Note: When programming ATRTIM and ATRSAM, the value of ATRTIM must be greater than ATRSAM to prevent the line from being flagged as STUCK.
10:6	ATRTIM	RW	0	Answer-to-Reset/Rest Period This field indicates the answer-to-reset period in 16 μ s units. If the SKATR bit is set in the ONEWIRECS register, this value indicates the rest period after reset. Note: When programming ATRTIM and ATRSAM, the value of ATRTIM must be greater than ATRSAM to prevent the line from being flagged as STUCK.
5:0	RSTTIM	RW	0	Reset Low Time Indicates the time reset is low in 32 μ s units.

Register 3: 1-Wire Data Write (ONEWIREDATW), offset 0x008

The **1-Wire Data Write (ONEWIREDATW)** and **1-Wire Data Read (ONEWIREDATR)** registers are used to transmit or receive data. Data is processed LSB first, which means the lowest (and possibly only) byte is transferred first. Note that for normal processor use of writing and write/read, the **ONEWIREDATW** register must be written before the **OP** field of the **ONEWIRECS** register is programmed. If reading (or write/read), the **ONEWIREDATR** register is read after completion (when **OP** returns to value 0). When doing write/read (**OP=0x3**), either register can be written. Because bits written as a 1 in the **ONEWIREDATR** register also act as a read, writing 0xFF is the same as a read of two bytes. Writing 0xF0 allows writing 0 for the lower nibble and reading the upper nibble. If the slave does not know it is a read, each written 1 reads back as 1.

1-Wire Data Write (ONEWIREDATW)

Base 0x400B.6000
Offset 0x008
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:24	B3	RW	0x00	Upper Data Byte This data byte is used when SZ field = 3.
23:16	B2	RW	0x00	Upper Middle Data Byte Contains upper middle data byte and is used when SZ field = 2 or 3.
15:8	B1	RW	0x00	Lower Middle Data Byte Contains lower middle data byte and is used when SZ field = 1, 2, or 3.
7:0	B0	RW	0x00	Lowest Data Byte Contains byte data being read or written (depending on the operation). This byte is always used.

Register 4: 1-Wire Data Read (ONEWIREDATR), offset 0x00C

The **1-Wire Data Write (ONEWIREDATW)** and **1-Wire Data Read (ONEWIREDATR)** registers are used to transmit or receive data. Data is processed LSB first, which means the lowest (and possibly only) byte is transferred first. Note that for normal processor use of writing and write/read, the **ONEWIREDATW** register must be written before the **OP** field of the **ONEWIRECS** register is programmed. If reading (or write/read), the **ONEWIREDATR** register is read after completion (when **OP** returns to value 0). When doing write/read (**OP=0x3**), either register can be written. Because bits written as a 1 in the **ONEWIREDATR** register also act as a read, writing 0xFF is the same as a read of two bytes. Writing 0xF0 allows writing 0 for the lower nibble and reading the upper nibble. If the slave does not know it is a read, each written 1 reads back as 1.

1-Wire Data Read (ONEWIREDATR)

Base 0x400B.6000
Offset 0x00C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:24	B3	RW	0x00	Upper Data Byte This data byte is used when SZ field = 3.
23:16	B2	RW	0x00	Upper Middle Data Byte Contains upper middle data byte and is used when SZ field = 2 or 3.
15:8	B1	RW	0x00	Lower Middle Data Byte Contains lower middle data byte and is used when SZ field = 1, 2, or 3.
7:0	B0	RW	0x00	Lowest Data Byte Contains byte data being read or written (depending on the operation). This byte is always used.

Register 5: 1-Wire Interrupt Mask (ONEWIREIM), offset 0x100

The **1-Wire Interrupt Mask (ONEWIREIM)** register enables the interrupt triggers for the 1-Wire Module.

1-Wire Interrupt Mask (ONEWIREIM)

Base 0x400B.6000
Offset 0x100
Type RW, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value	Description									
0	The reset interrupt is suppressed and not sent to the interrupt controller.									
1	The reset interrupt is sent to the interrupt controller when the RST bit in the ONEWIRERIS register is set.									

Register 6: 1-Wire Raw Interrupt Status (ONEWIRERIS), offset 0x104

The **1-Wire Raw Interrupt Status (ONEWIRERIS)** register contains the raw interrupt status. If any of these bits read 1, the processor is interrupted if the corresponding masked interrupt status bit is set.

1-Wire Raw Interrupt Status (ONEWIRERIS)

Base 0x400B.6000
Offset 0x104
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	DMA	RO	0	DMA Done Raw Interrupt Status Value Description 0 No interrupt 1 DMA transfer complete and an interrupt is pending.
3	STUCK	RO	0	Stuck Status Raw Interrupt Status When unmasked, this interrupt indicates a line-hold-low error is detected. Value Description 0 No interrupt 1 Stuck status (line-hold-error) is detected and an interrupt is pending.
2	NOATR	RO	0	No Answer-to-Reset Raw Interrupt Status Value Description 0 No interrupt 1 A No Answer-to-Reset is detected from the last reset and an interrupt is pending.

Bit/Field	Name	Type	Reset	Description						
1	OPC	RO	0	<p>Operation Complete Raw Interrupt Status</p> <p>This bit indicates when a read, write or read/write operation has completed.</p> <p>If a read or read/write transfer has occurred then the read data is ready to be accessed when this bit is set.</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>No interrupt.</td></tr><tr><td>1</td><td>The last write, read, or write/read has completed and an interrupt is pending.</td></tr></tbody></table>	Value	Description	0	No interrupt.	1	The last write, read, or write/read has completed and an interrupt is pending.
Value	Description									
0	No interrupt.									
1	The last write, read, or write/read has completed and an interrupt is pending.									
0	RST	RO	0	<p>Reset Raw Interrupt Status</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>No interrupt.</td></tr><tr><td>1</td><td>The last reset completed and an interrupt is pending.</td></tr></tbody></table>	Value	Description	0	No interrupt.	1	The last reset completed and an interrupt is pending.
Value	Description									
0	No interrupt.									
1	The last reset completed and an interrupt is pending.									

Register 7: 1-Wire Masked Interrupt Status (ONEWIREMIS), offset 0x108

The **1-Wire Masked Interrupt Status (ONEWIREMIS)** register indicates when an unmasked interrupt has occurred.

1-Wire Masked Interrupt Status (ONEWIREMIS)

Base 0x400B.6000
Offset 0x108
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	DMA	RO	0	DMA Done Masked Interrupt Status
		Value	Description	
		0	No interrupt	
		1	A DMA transfer is complete and an unmasked interrupt is pending.	
3	STUCK	RO	0	Stuck Status Masked Interrupt Status
		Value	Description	
		0	No interrupt	When unmasked, this interrupt indicates a line-hold-low error is detected.
		1	An unmasked Stuck status (line-hold-error) interrupt is detected and pending.	
2	NOATR	RO	0	No Answer-to-Reset Masked Interrupt Status
		Value	Description	
		0	No interrupt	
		1	A No Answer-to-Reset unmasked interrupt is detected from the last reset and pending.	
1	OPC	RO	0	Operation Complete Masked Interrupt Status
		Value	Description	
		0	No Interrupt	
		1	An unmasked operation complete interrupt is pending.	

Bit/Field	Name	Type	Reset	Description
0	RST	RO	0	Reset Interrupt Mask
				Value Description
			0	No Interrupt.
			1	The unmasked reset interrupt is pending.

Register 8: 1-Wire Interrupt Clear (ONEWIREICR), offset 0x10C

The **1-Wire Interrupt Clear (ONEWIREICR)** register is used to clear the **ONEWIRERIS** register (and by extension, the **ONEWIREMIS** register). When read, this register contains the same value as the **ONEWIRERIS** register. To clear current interrupts, read this register and write the results back.

1-Wire Interrupt Clear (ONEWIREICR)

Base 0x400B.6000
Offset 0x10C
Type RW1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:5	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	DMA	W1C	0	DMA Done Interrupt Clear Writing a 1 to this bit clears the DMA bit in the ONEWIRERIS register and the DMA bit in the ONEWIREMIS register.
3	STUCK	W1C	0	Stuck Status Interrupt Clear Writing a 1 to this bit clears the STUCK bit in the ONEWIRERIS register and the STUCK bit in the ONEWIREMIS register.
2	NOATR	W1C	0	No Answer-to-Reset Interrupt Clear Writing a 1 to this bit clears the NOATR bit in the ONEWIRERIS register and the NOATR bit in the ONEWIREMIS register.
1	OPC	W1C	0	Operation Complete Interrupt Clear Writing a 1 to this bit clears the OPC bit in the ONEWIRERIS register and the OPC bit in the ONEWIREMIS register.
0	RST	W1C	0	Reset Interrupt Clear Writing a 1 to this bit clears the RST bit in the ONEWIRERIS register and the RST bit in the ONEWIREMIS register.

Register 9: 1-Wire µDMA Control (ONEWIREDMA), offset 0x120

The **1-Wire DMA Control (ONEWIREDMA)** register is used to configure the µDMA operation for 1-Wire. This mechanism supports both µDMA write operations, µDMA read operations, small write/read operations, and scatter-gather support of mixed operations.

Note: This register is cleared when the `dma_done` signal to the 1-Wire module is asserted by the µDMA and the `DMA` bit in the **ONEWIRERIS** register is set.

1-Wire µDMA Control (ONEWIREDMA)

Base 0x400B.6000
Offset 0x120
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description										
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										
3	SG	RW	0	<p>Scatter-Gather Enable</p> <p>This bit should be enabled when <code>DMAOP</code> = 0x1 and the scatter-gather method is being used.</p> <p>This bit self clears after it has performed the µDMA request.</p> <table border="1"> <tr> <td>Value</td><td>Description</td></tr> <tr> <td>0</td><td>No effect</td></tr> <tr> <td>1</td><td>µDMA is requested at start of operation and all requests after are on completion of transactions.</td></tr> </table>	Value	Description	0	No effect	1	µDMA is requested at start of operation and all requests after are on completion of transactions.				
Value	Description													
0	No effect													
1	µDMA is requested at start of operation and all requests after are on completion of transactions.													
2:1	DMAOP	RW	0x0	<p>µDMA Operation</p> <p>The programmed operation starts when reset completes if the <code>RST</code> bit in the ONEWIRECS register is set. 23 Controller Area Network (CAN) Module

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

The TM4C129XKCZAD microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the CANnTX and CANnRX signals

23.1 Block Diagram

Figure 23-1. CAN Controller Block Diagram

23.2 Signal Description

The following table lists the external signals of the CAN controller and describes the function of each. The CAN controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the CAN signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the CAN controller function. The number in parentheses is the encoding that must be programmed into the PMCn field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the CAN signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769.

Table 23-1. Controller Area Network Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
CAN0Rx	V3 W10	PA0 (7) PT0 (7)	I	TTL	CAN module 0 receive.
CAN0Tx	W3 V10	PA1 (7) PT1 (7)	O	TTL	CAN module 0 transmit.
CAN1Rx	A16 E18	PB0 (7) PT2 (7)	I	TTL	CAN module 1 receive.
CAN1Tx	B16 F17	PB1 (7) PT3 (7)	O	TTL	CAN module 1 transmit.

23.3 Functional Description

The TM4C129XKCZAD CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 23-2.

Figure 23-2. CAN Data/Remote Frame

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These memory blocks are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the TM4C129XKCZAD memory map, so the TM4C129XKCZAD CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. These two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

23.3.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 411). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (see page 411). To find out which GPIO port to enable, refer to Table 31-4 on page 2068. Set the GPIO **AFSEL** bits for the appropriate pins (see page 799). Configure the **PMCn** fields in the **GPIOPCTL** register to assign the CAN signals to the appropriate pins. See page 816 and Table 31-5 on page 2085.

Software initialization is started by setting the **INIT** bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While **INIT** is set, all message transfers to and from the CAN bus are stopped and the **CANnTX** signal is held High. Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the **MSGVAL** bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the **INIT** and **CCE** bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the **INIT** bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the **MSGVAL** bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the **MSGVAL** bit again to indicate that the message object is once again valid.

23.3.2 Operation

Two sets of CAN Interface Registers (**CANIFn1x** and **CANIFn2x**) are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to

queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the INIT bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the MNUM bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the MSK bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. Message objects can be used for one-time data transfers or can be permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate TXRQST bit in the **CAN Transmission Request n (CANTXRQn)** register and the NEWDAT bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (MNUM) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the RMTEN bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the TXRQST bit to be set, and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. A remote frame can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The UMASK bit in the **CANIFnMCTL** register enables the MSK bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The MXTD bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

23.3.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if a data transfer is not occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's NEWDAT bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the TXRQST bit in the **CANTXRQn** register is cleared. If the CAN controller is configured to interrupt on a successful transmission of a message object, (the TXIE bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the INTPND bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is

re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

23.3.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
 - Set the WRNRD bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the IDMASK, DIR, and MXTD of the message object into the **CAN IFn** registers using the MASK bit
 - Specify whether to transfer the ID, DIR, XTD, and MSGVAL of the message object into the interface registers using the ARB bit
 - Specify whether to transfer the control bits into the interface registers using the CONTROL bit
 - Specify whether to clear the INTPND bit in the **CANIFnMCTL** register using the CLRINTPND bit
 - Specify whether to clear the NEWDAT bit in the **CANNWDAn** register using the NEWDAT bit
 - Specify which bits to transfer using the DATAA and DATAB bits
2. In the **CANIFnMSK1** register, use the MSK[15:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[15:0] in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure ID[15:0] in the **CANIFnARB1** register for bits [15:0] of the message identifier and ID[12:0] in the **CANIFnARB2** register for bits [28:16] of the message identifier. Set the XTD bit to indicate an extended identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure ID[12:2] in the **CANIFnARB2** register for bits [10:0] of the message identifier. Clear the XTD bit to indicate a standard identifier; set the DIR bit to indicate transmit; and set the MSGVAL bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:

- Optionally set the `UMASK` bit to enable the mask (`MSK`, `MXTD`, and `MDIR` specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
 - Optionally set the `TXIE` bit to enable the `INTPND` bit to be set after a successful transmission
 - Optionally set the `RMTEN` bit to enable the `TXRQST` bit to be set on the reception of a matching remote frame allowing automatic transmission
 - Set the `EOB` bit for a single message object
 - Configure the `DLC[3:0]` field to specify the size of the data frame. Take care during this configuration not to set the `NEWDAT`, `MSGLST`, `INTPND` or `TXRQST` bits.
7. Load the data to be transmitted into the **CAN IFn Data (CANIFnDA1, CANIFnDA2, CANIFnDB1, CANIFnDB2)** registers. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register.
 8. Program the number of the message object to be transmitted in the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register.
 9. When everything is properly configured, set the `TXRQST` bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the `RMTEN` bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

23.3.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the `MSGVAL` bit in the **CANIFnARB2** register nor the `TXRQST` bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the `WRNRD`, `DATAA` and `DATAB` bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** registers, and then the number of the message object is written to the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the `TXRQST` bit in the **CANIFnMSKn** register.

To prevent the clearing of the `TXRQST` bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the `NEWDAT` and `TXRQST` bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, `NEWDAT` is cleared as soon as the new transmission has started.

23.3.6 Accepting Received Message Objects

When the arbitration and control field (the `ID` and `XTD` bits in the **CANIFnARB2** and the `RMTEN` and `DLC[3:0]` bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the `UMASK` bit in the **CANIFnMCTL** register. Each valid

message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

23.3.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the DLC bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The NEWDAT bit of the **CANIFnMCTL** register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the NEWDAT bit is already set, the MSGLST bit in the **CANIFnMCTL** register is set to indicate that the previous data was lost. If the system requires an interrupt on successful reception of a frame, the RXIE bit of the **CANIFnMCTL** register should be set. In this case, the INTPND bit of the same register is set, causing the **CANINT** register to point to the message object that just received a message. The TXRQST bit of this message object should be cleared to prevent the transmission of a remote frame.

23.3.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

Table 23-2. Message Object Configurations

Configuration in CANIFnMCTL	Description
<ul style="list-style-type: none"> ■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register ■ RMTEN = 1 (set the TXRQST bit of the CANIFnMCTL register at reception of the frame to enable transmission) ■ UMASK = 1 or 0 	At the reception of a matching remote frame, the TXRQST bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible.
<ul style="list-style-type: none"> ■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register ■ RMTEN = 0 (do not change the TXRQST bit of the CANIFnMCTL register at reception of the frame) ■ UMASK = 0 (ignore mask in the CANIFnMSKn register) 	At the reception of a matching remote frame, the TXRQST bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and nothing indicates that the remote frame ever happened.
<ul style="list-style-type: none"> ■ DIR = 1 (direction = transmit); programmed in the CANIFnARB2 register ■ RMTEN = 0 (do not change the TXRQST bit of the CANIFnMCTL register at reception of the frame) ■ UMASK = 1 (use mask (MSK, MXTD, and MDIR in the CANIFnMSKn register) for acceptance filtering) 	At the reception of a matching remote frame, the TXRQST bit of this message object is cleared. The arbitration and control field (ID + XTD + RMTEN + DLC) from the shift register is stored into the message object in the message RAM, and the NEWDAT bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This mode is useful for a remote data request from another CAN device for which the TM4C129XKCZAD controller does not have readily available data. The software must fill the data and answer the frame manually.

23.3.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This prioritization is separate from that of the message identifier which is enforced by the CAN bus. As a result, if message object 1 and message object 2 both have valid messages to be transmitted, message object 1 is always transmitted first regardless of the message identifier in the message object itself.

23.3.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 1537 section, except that the **WRNRD** bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 1537 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the **UMASK** bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the **MSK[12:0]** bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that **MSK[12:0]** are used for bits [28:16] of the 29-bit message identifier; whereas **MSK[12:2]** are used for bits [10:0] of the 11-bit message identifier. Use the **MXTD** and **MDIR** bits to specify whether to use **XTD** and **DIR** for acceptance filtering. A value of **0x00** enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the **UMASK** bit in the **CANIFnMCTL** register.
4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 1537 section to program **XTD** and **ID** bits for the message identifier to be received; set the **MSGVAL** bit to indicate a valid message; and clear the **DIR** bit to specify receive.
5. In the **CANIFnMCTL** register:
 - Optionally set the **UMASK** bit to enable the mask (**MSK**, **MXTD**, and **MDIR** specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
 - Optionally set the **RXIE** bit to enable the **INTPND** bit to be set after a successful reception
 - Clear the **RMTEN** bit to leave the **TXRQST** bit unchanged
 - Set the **EOB** bit for a single message object
 - Configure the **DLC[3:0]** field to specify the size of the data frame
 Take care during this configuration not to set the **NEWDAT**, **MSGLST**, **INTPND** or **TXRQST** bits.
6. Program the number of the message object to be received in the **MNUM** field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in DATA[7:0] in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are received by a message object. The **UMASK** bit in the **CANIFnMCTL** register enables the **MSK** bits in the **CANIFnMSKn** register to filter which frames are received. The **MXTD** bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

23.3.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CANIFnCMSK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the **NEWDAT** and **INTPND** bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARBn** registers show the full, unmasked ID for the received message.

The **NEWDAT** bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The **MSGLST** bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object was read. **MSGLST** is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the **TXRQST** bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the **TXRQST** bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

23.3.11.1 Configuration of a FIFO Buffer

With the exception of the **EOB** bit in the **CANIFnMCTL** register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see “Configuring a Receive Message Object” on page 1540). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The **EOB** bit of all message objects of a FIFO buffer except the last one must be cleared. The **EOB** bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

23.3.11.2 Reception of Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the **NEWDAT** of the **CANIFnMCTL** register bit of this message object is set. By setting

NEWDAT while EOB is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the NEWDAT bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. Until all of the preceding message objects have been released by clearing the NEWDAT bit, all further messages for this FIFO buffer are written into the last message object of the FIFO buffer and therefore overwrite previous messages.

23.3.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the **CANIFnCRQ** register, the TXRQST and CLRINTPND bits in the **CANIFnCMSK** register should be set such that the NEWDAT and INTPEND bits in the **CANIFnMCTL** register are cleared after the read. The values of these bits in the **CANIFnMCTL** register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. When reading from the FIFO buffer, the user should be aware that a new received message is placed in the message object with the lowest message number for which the NEWDAT bit of the **CANIFnMCTL** register is clear. As a result, the order of the received messages in the FIFO is not guaranteed. Figure 23-3 on page 1543 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 23-3. Message Objects in a FIFO Buffer

23.3.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest

priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's INTPND bit in the **CANIFnMCTL** register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier INTID in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as 0x0000. If the value of the INTID field is different from 0, then an interrupt is pending. If the IE bit is set in the **CANCTL** register, the interrupt line to the interrupt controller is active. The interrupt line remains active until the INTID field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until IE is cleared, which disables interrupts from the CAN controller.

The INTID field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The SIE bit in the **CANCTL** register controls whether a change of the RXOK, TXOK, and LEC bits in the **CANSTS** register can cause an interrupt. The EIE bit in the **CANCTL** register controls whether a change of the BOFF and EWARN bits in the **CANSTS** register can cause an interrupt. The IE bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the interrupt controller. The **CANINT** register is updated even when the IE bit in the **CANCTL** register is clear, but the interrupt is not indicated to the CPU.

A value of 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the RXOK, TXOK, and LEC bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

The source of an interrupt can be determined in two ways during interrupt handling. The first is to read the INTID bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's INTPND bit at the same time by setting the CLRINTPND bit in the **CANIFnCMSK** register. Once the INTPND bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

23.3.13 Test Mode

A Test Mode is provided which allows various diagnostics to be performed. Test Mode is entered by setting the TEST bit in the **CANCTL** register. Once in Test Mode, the TX[1:0], LBACK, SILENT and BASIC bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The RX bit in the **CANTST** register allows monitoring of the CANnRX signal. All **CANTST** register functions are disabled when the TEST bit is cleared.

23.3.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the SILENT bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

23.3.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the CANnTX signal on to the CANnRX signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the LBACK bit in the **CANTST** register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the CANnRX signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the CANnTX signal.

23.3.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the CANnTX and CANnRX signals. In this mode, the CANnRX signal is disconnected from the CAN Controller and the CANnTX signal is held recessive. This mode is enabled by setting both the LBACK and SILENT bits in the **CANTST** register.

23.3.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the BUSY bit of the **CANIF1CRQ** register. The CANIF1 registers are locked while the BUSY bit is set. The BUSY bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the BUSY bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the BUSY bit in the **CANIF1CRQ** register while the CANIF1 registers are locked. If the CPU has cleared the BUSY bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register are stored in the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the BUSY bit of the **CANIF2CRQ** register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the **CANIFnCMSK** registers are not evaluated. The message number of the **CANIFnCRQ** registers is also not evaluated. In the **CANIF2MCTL** register, the NEWDAT and MSGLST bits retain their function, the **DLC[3:0]** field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the BASIC bit in the **CANTST** register.

23.3.13.5 Transmit Control

Software can directly override control of the CANnTX signal in four different ways.

- CANnTX is controlled by the CAN Controller
- The sample point is driven on the CANnTX signal to monitor the bit timing
- CANnTX drives a low value
- CANnTX drives a high value

The last two functions, combined with the readable CAN receive pin CANnRX, can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the TX[1:0] field in the **CANTST** register. The three test functions for the CANnTX signal interfere with all CAN protocol functions. TX[1:0] must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

23.3.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

23.3.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 23-4 on page 1547): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 23-3 on page 1547). The length of the time quantum (t_q), which is the basic time unit of the bit time, is defined by the CAN controller's input clock (f_{sys}) and the Baud Rate Prescaler (BRP):

$$t_q = BRP / f_{sys}$$

The f_{sys} input clock is the system clock frequency as configured by the **RSCLKCFG** register (see page 286).

The Synchronization Segment Sync is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of Sync and the Sync is called the phase error of that edge.

The Propagation Time Segment Prop is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase1 and Phase2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 23-4. CAN Bit Time**Table 23-3. CAN Protocol Ranges^a**

Parameter	Range	Remark
BRP	[1 .. 64]	Defines the length of the time quantum t_q . The CANBRPE register can be used to extend the range to 1024.
Sync	$1 t_q$	Fixed length, synchronization of bus input to system clock
Prop	[1 .. 8] t_q	Compensates for the physical delay times
Phase1	[1 .. 8] t_q	May be lengthened temporarily by synchronization
Phase2	[1 .. 8] t_q	May be shortened temporarily by synchronization
SJW	[1 .. 4] t_q	May not be longer than either Phase Buffer Segment

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. In the **CANBIT** register, the four components TSEG2, TSEG1, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits in the SJW bit field. Table 23-4 shows the relationship between the **CANBIT** register values and the parameters.

Table 23-4. CANBIT Register Values

CANBIT Register Field	Setting
TSEG2	Phase2 - 1
TSEG1	Prop + Phase1 - 1
SJW	SJW - 1
BRP	BRP

Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync + Prop + Phase1 + Phase2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time

unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. In addition, the controller generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. The bit value is received or transmitted at the sample point. The information processing time (IPT) is the time after the sample point needed to calculate the next bit to be transmitted on the CAN bus. The IPT includes any of the following: retrieving the next data bit, handling a CRC bit, determining if bit stuffing is required, generating an error flag or simply going idle.

The IPT is application-specific but may not be longer than $2 t_q$; the CAN's IPT is $0 t_q$. Its length is the lower limit of the programmed length of Phase2. In case of synchronization, Phase2 may be shortened to a value less than IPT, which does not affect bus timing.

23.3.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is Prop. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop is converted into time quanta (rounded up to the nearest integer multiple of t_q).

Sync is $1 t_q$ long (fixed), which leaves (bit time - Prop - 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, that is, Phase2 = Phase1, else Phase2 = Phase1 + 1.

The minimum nominal length of Phase2 has to be regarded as well. Phase2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of [0..2] t_q .

The length of the synchronization jump width is set to the least of 4, Phase1 or Phase2.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- df = Maximum tolerance of oscillator frequency
- f_{osc} = Actual oscillator frequency
- f_{nom} = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(Phase_seg1, Phase_seg2) \min}{2 \times (13 \times tbit - Phase_Seg2)}$$

$$df \max = 2 \times df \times f_{nom}$$

where:

- Phase1 and Phase2 are from Table 23-3 on page 1547
- tbit = Bit Time
- dfmax = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

23.3.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

```

bit time = 1 μs = n * tq = 5 * tq
tq = 200 ns
tq = (Baud rate Prescaler)/CAN Clock
Baud rate Prescaler = tq * CAN Clock
Baud rate Prescaler = 200E-9 * 25E6 = 5

tSync = 1 * tq = 200 ns          \\fixed at 1 time quanta

delay of bus driver 50 ns
delay of receiver circuit 30 ns
delay of bus line (40m) 220 ns
tProp 400 ns = 2 * tq          \\400 is next integer multiple of tq

bit time = tSync + tTSeg1 + tTSeg2 = 5 * tq
bit time = tSync + tProp + tPhase 1 + tPhase2
tPhase 1 + tPhase2 = bit time - tSync - tProp
tPhase 1 + tPhase2 = (5 * tq) - (1 * tq) - (2 * tq)
tPhase 1 + tPhase2 = 2 * tq
tPhase1 = 1 * tq
tPhase2 = 1 * tq          \\tPhase2 = tPhase1

```

```

tTSeg1 = tProp + tPhase1
tTSeg1 = (2 * tq) + (1 * tq)
tTSeg1 = 3 * tq

tTSeg2 = tPhase2
tTSeg2 = (Information Processing Time + 1) * tq
tTSeg2 = 1 * tq                                \\Assumes IPT=0

tSJW = 1 * tq                                \\Least of 4, Phase1 and Phase2

```

In the above example, the bit field values for the **CANBIT** register are:

TSEG2	= TSeg2 -1 = 1-1 = 0
TSEG1	= TSeg1 -1 = 3-1 = 2
SJW	= SJW -1 = 1-1 = 0
BRP	= Baud rate prescaler - 1 = 5-1 =4

The final value programmed into the **CANBIT** register = 0x0204.

23.3.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

```

bit time = 10 μs = n * tq = 10 * tq
tq = 1 μs
tq = (Baud rate Prescaler)/CAN Clock
Baud rate Prescaler = tq * CAN Clock
Baud rate Prescaler = 1E-6 * 50E6 = 50

tSync = 1 * tq = 1 μs                      \\fixed at 1 time quanta

delay of bus driver 200 ns
delay of receiver circuit 80 ns
delay of bus line (40m) 220 ns
tProp 1 μs = 1 * tq                         \\1 μs is next integer multiple of tq

bit time = tSync + tTSeg1 + tTSeg2 = 10 * tq
bit time = tSync + tProp + tPhase1 + tPhase2
tPhase1 + tPhase2 = bit time - tSync - tProp
tPhase1 + tPhase2 = (10 * tq) - (1 * tq) - (1 * tq)
tPhase1 + tPhase2 = 8 * tq
tPhase1 = 4 * tq
tPhase2 = 4 * tq                            \\tPhase1 = tPhase2

```

```

tTSeg1 = tProp + tPhase1
tTSeg1 = (1 * tq) + (4 * tq)
tTSeg1 = 5 * tq
tTSeg2 = tPhase2
tTSeg2 = (Information Processing Time + 4) × tq
tTSeg2 = 4 * tq                                \\Assumes IPT=0

tSJW = 4 * tq                                \\Least of 4, Phase1, and Phase2

```

TSEG2	= TSeg2 -1 = 4-1 = 3
TSEG1	= TSeg1 -1 = 5-1 = 4
SJW	= SJW -1 = 4-1 = 3
BRP	= Baud rate prescaler - 1 = 50-1 =49

The final value programmed into the **CANBIT** register = 0x34F1.

23.4 Register Map

Table 23-5 on page 1551 lists the registers. All addresses given are relative to the CAN base address of:

- CAN0: 0x4004.0000
- CAN1: 0x4004.1000

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 411). There must be a delay of 3 system clocks after the CAN module clock is enabled before any CAN module registers are accessed.

23.5 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in

the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

Register 1: CAN Control (CANCTL), offset 0x000

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing INIT. If the device goes bus-off, it sets INIT, stopping all bus activities. Once INIT has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 * 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after INIT is cleared, each time a sequence of 11 High bits has been monitored, a BITERROR0 code is written to the **CANSTS** register (the LEC field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

Value	Description									
0	Normal operation.									
1	Initialization started.									

Register 2: CAN Status (CANSTS), offset 0x004

Important: This register is read-sensitive. See the register description for details.

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 0x7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits, and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors.		A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0).	0x5	Bit 0 Error		A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1).		During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.	0x6	CRC Error		The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data.	0x7	No Event		When the LEC bit shows this value, no CAN bus event was detected since this value was written to the LEC field.
Value	Description																																							
0x0	No Error																																							
0x1	Stuff Error																																							
	More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.																																							
0x2	Format Error																																							
	A fixed format part of the received frame has the wrong format.																																							
0x3	ACK Error																																							
	The message transmitted was not acknowledged by another node.																																							
0x4	Bit 1 Error																																							
	When a message is transmitted, the CAN controller monitors the data lines to detect any conflicts. When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors.																																							
	A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0).																																							
0x5	Bit 0 Error																																							
	A Bit 0 Error indicates that the device wanted to send a Low level (logical 0), but the monitored bus value was High (logical 1).																																							
	During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. By checking for this status, software can monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.																																							
0x6	CRC Error																																							
	The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data.																																							
0x7	No Event																																							
	When the LEC bit shows this value, no CAN bus event was detected since this value was written to the LEC field.																																							

Register 3: CAN Error Counter (CANERR), offset 0x008

This register contains the error counter values, which can be used to analyze the cause of an error.

CAN Error Counter (CANERR)

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x008

Type RO, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:16 reserved RO 0x0000 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

15 RP RO 0 Received Error Passive

Value Description

0 The Receive Error counter is below the Error Passive level (127 or less).

1 The Receive Error counter has reached the Error Passive level (128 or greater).

14:8 REC RO 0x00 Receive Error Counter

This field contains the state of the receiver error counter (0 to 127).

7:0 TEC RO 0x00 Transmit Error Counter

This field contains the state of the transmit error counter (0 to 255).

Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are programmed to the system clock frequency. This register is write-enabled by setting the CCE and INIT bits in the **CANCTL** register. See “Bit Time and Bit Rate” on page 1546 for more information.

CAN Bit Timing (CANBIT)

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x00C

Type RW, reset 0x0000.2301

Bit/Field	Name	Type	Reset	Description
31:15	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14:12	TSEG2	RW	0x2	<p>Time Segment after Sample Point</p> <p>0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.</p> <p>So, for example, the reset value of 0x2 means that 3 (2+1) bit time quanta are defined for Phase2 (see Figure 23-4 on page 1547). The bit time quanta is defined by the BRP field.</p>
11:8	TSEG1	RW	0x3	<p>Time Segment Before Sample Point</p> <p>0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.</p> <p>So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for Phase1 (see Figure 23-4 on page 1547). The bit time quanta is defined by the BRP field.</p>
7:6	SJW	RW	0x0	<p>(Re)Synchronization Jump Width</p> <p>0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.</p> <p>During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of TSEG2 or TSEG1 by the value in SJW. So the reset value of 0 adjusts the length by 1 bit time quanta.</p>
5:0	BRP	RW	0x1	<p>Baud Rate Prescaler</p> <p>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.</p> <p>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.</p> <p>BRP defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).</p> <p>The CANBRPE register can be used to further divide the bit time.</p>

Register 5: CAN Interrupt (CANINT), offset 0x010

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the **INTID** field is not 0x0000 (the default) and the **IE** bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the **INTID** field is cleared by reading the **CANSTS** register, or until the **IE** bit in the **CANCTL** register is cleared.

Note: Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

CAN Interrupt (CANINT)

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x010

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	INTID	RO	0x0000	Interrupt Identifier The number in this field indicates the source of the interrupt.

Value	Description
0x0000	No interrupt pending
0x0001-0x0020	Number of the message object that caused the interrupt
0x0021-0x7FFF	Reserved
0x8000	Status Interrupt
0x8001-0xFFFF	Reserved

Register 6: CAN Test (CANTST), offset 0x014

This register is used for self-test and external pin access. It is write-enabled by setting the TEST bit in the **CANCTL** register. Different test functions may be combined, however, CAN transfers are affected if the TX bits in this register are not zero.

CAN Test (CANTST)

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x014

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	RX	RO	0	Receive Observation
		Value		Description
		0		The CANnRx pin is low.
		1		The CANnRx pin is high.
6:5	TX	RW	0x0	Transmit Control Overrides control of the CANnTx pin.
		Value		Description
		0x0		CAN Module Control CANnTx is controlled by the CAN module; default operation
		0x1		Sample Point The sample point is driven on the CANnTx signal. This mode is useful to monitor bit timing.
		0x2		Driven Low CANnTx drives a low value. This mode is useful for checking the physical layer of the CAN bus.
		0x3		Driven High CANnTx drives a high value. This mode is useful for checking the physical layer of the CAN bus.

1	Basic mode is enabled. In basic mode, software should use the CANIF1 registers as the transmit buffer and use the CANIF2 registers as the receive buffer.									
1:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						

Register 7: CAN Baud Rate Prescaler Extension (CANBRPE), offset 0x018

This register is used to further divide the bit time set with the **BRP** bit in the **CANBIT** register. It is write-enabled by setting the **CCE** bit in the **CANCTL** register.

CAN Baud Rate Prescaler Extension (CANBRPE)

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x018

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	BRPE	RW	0x0	Baud Rate Prescaler Extension 0x00-0x0F: Extend the BRP bit in the CANBIT register to values up to 1023. The actual interpretation by the hardware is one more than the value programmed by BRPE (MSBs) and BRP (LSBs).

Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020**Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the **CANIF1MCTL** register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

CAN IFn Command Request (CANIFnCRQ)

CAN0 base: 0x4004.0000
 CAN1 base: 0x4004.1000
 Offset 0x020
 Type RW, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15	BUSY	RO	0	Busy Flag
		Value		Description
		0		This bit is cleared when read/write action has finished.
		1		This bit is set when a write occurs to the message number in this register.
14:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:0	MNUM	RW	0x01	Message Number
		Value		Description
		0x00		Reserved
		0x01-0x20		0 is not a valid message number; it is interpreted as 0x20, or object 32.
		0x21-0x3F		Message Number Indicates specified message object 1 to 32. Reserved Not a valid message number; values are shifted and it is interpreted as 0x01-0x1F.

Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024**Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084**

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

CAN IFn Command Mask (CANIFnCMSK)

CAN0 base: 0x4004.0000

CAN1 base: 0x4004.1000

Offset 0x024

31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

15	MSGVAL	RW	0	Message Valid
				Value Description
			0	The message object is ignored by the message handler.
			1	The message object is configured and ready to be considered by the message handler within the CAN controller.

All unused message objects should have this bit cleared during initialization and before clearing the INIT bit in the **CANCTL** register. The MSGVAL bit must also be cleared before any of the following bits are modified or if the message object is no longer required: the ID fields in the **CANIFnARBn** registers, the XTD and DIR bits in the **CANIFnARB2** register, or the DLC field in the **CANIFnMCTL** register.

14	XTD	RW	0	Extended Identifier
				Value Description
			0	An 11-bit Standard Identifier is used for this message object.
			1	A 29-bit Extended Identifier is used for this message object.

Bit/Field	Name	Type	Reset	Description						
13	DIR	RW	0	Message Direction						
				<table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Receive. When the TXRQST bit in the CANIFnMCTL register is set, a remote frame with the identifier of this message object is received. On reception of a data frame with matching identifier, that message is stored in this message object.</td></tr> <tr> <td>1</td><td>Transmit. When the TXRQST bit in the CANIFnMCTL register is set, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TXRQST bit of this message object is set (if RMTEN=1).</td></tr> </tbody> </table>	Value	Description	0	Receive. When the TXRQST bit in the CANIFnMCTL register is set, a remote frame with the identifier of this message object is received. On reception of a data frame with matching identifier, that message is stored in this message object.	1	Transmit. When the TXRQST bit in the CANIFnMCTL register is set, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TXRQST bit of this message object is set (if RMTEN=1).
Value	Description									
0	Receive. When the TXRQST bit in the CANIFnMCTL register is set, a remote frame with the identifier of this message object is received. On reception of a data frame with matching identifier, that message is stored in this message object.									
1	Transmit. When the TXRQST bit in the CANIFnMCTL register is set, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TXRQST bit of this message object is set (if RMTEN=1).									
12:0	ID	RW	0x000	<p>Message Identifier</p> <p>This bit field is used with the ID field in the CANIFnARB2 register to create the message identifier.</p> <p>When using a 29-bit identifier, ID[15:0] of the CANIFnARB1 register are [15:0] of the ID, while these bits, ID[12:0], are [28:16] of the ID.</p> <p>When using an 11-bit identifier, ID[12:2] are used for bits [10:0] of the ID. The ID field in the CANIFnARB1 register is ignored.</p>						

Register 20: CAN IF1 Message Control (CANIF1MCTL), offset 0x038**Register 21: CAN IF2 Message Control (CANIF2MCTL), offset 0x098**

This register holds the control information associated with the message object to be sent to the Message RAM.

15:0	DATA	RW	0x0000	The CANIFnDA1 registers contain data bytes 1 and 0; CANIFnDA2 data bytes 3 and 2; CANIFnDB1 data bytes 5 and 4; and CANIFnDB2 data bytes 7 and 6.

Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100

Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104

The **CANTXRQ1** and **CANTXRQ2** registers hold the TXRQST bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The TXRQST bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a remote frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the TXRQST bits of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the TXRQST bits of the second 16 message objects.

		Value		Description
		0		The corresponding message object is not configured and is ignored by the message handler.
		1		The corresponding message object is configured and should be considered by the message handler.

24 Ethernet Controller

The Ethernet Controller has the following features:

- Conforms to the IEEE 802.3 specification
 - 10BASE-T/100BASE-TX IEEE-802.3 compliant
 - Supports 10/100 Mbps data transmission rates
 - Supports full-duplex and half-duplex (CSMA/CD) operation
 - Supports flow control and back pressure
 - Full-featured and enhanced auto-negotiation
 - Supports IEEE 802.1Q VLAN tag detection
- Conforms to IEEE 1588-2002 Timestamp Precision Time Protocol (PTP) protocol and the IEEE 1588-2008 Advanced Timestamp specification
 - Transmit and Receive frame time stamping
 - Precision Time Protocol
 - Flexible pulse per second output
 - Supports coarse and fine correction methods
- Multiple addressing modes
 - Four MAC address filters
 - Programmable 64-bit Hash Filter for multicast address filtering
 - Promiscuous mode support
- Processor offloading
 - Programmable insertion (TX) or deletion (RX) of preamble and start-of-frame data
 - Programmable generation (TX) or deletion (RX) of CRC and pad data
 - IP header and hardware checksum checking (IPv4, IPv6, TCP/UDP/ICMP)
- Highly configurable
 - LED activity selection
 - Supports network statistics with RMON/MIB counters
 - Supports Magic Packet and wakeup frames
- Efficient transfers using integrated Direct Memory Access (DMA)
 - Dual-buffer (ring) or linked-list (chained) descriptors

- Round-robin or fixed priority arbitration between TX/RX
- Descriptors support up to 8 kB transfer blocks size
- Programmable interrupts for flexible system implementation
- Physical media manipulation
 - MDI/MDI-X cross-over support
 - Register-programmable transmit amplitude
 - Automatic polarity correction and 10BASE-T signal reception
- MII and RMII interface support

24.1 Block Diagram

Figure 24-1 on page 1584 shows the block diagram of the Ethernet MAC with an integrated PHY interface:

Figure 24-1. Ethernet MAC with Integrated PHY Interface

24.2 Signal Description

The following table lists the external signals of the Ethernet Controller and describes the function of each. Some of the Ethernet signals have dedicated functions while the others listed in the table are alternate functions for GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these Ethernet module signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to assign the Ethernet signals. The number in parentheses is the encoding that must be programmed into the PMCn field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the Ethernet signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Table 24-1. Ethernet Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
EN0COL	N18	PM7 (14)	I	TTL	Ethernet 0 Collision Detect.

EN0TXOP	V15	fixed	I/O	TTL	Ethernet PHY positive transmit differential output.
RBIAS	W15	fixed	O	Analog	4.87-kΩ resistor (1% precision) for Ethernet PHY.

24.3 Functional Description

The Ethernet Controller is made up of the following sub-modules:

- Clock Control
- MII/RMII Interface Module
- DMA Controller
- Transmit/Receive Controller (TX/RX Controller)
- Media Access Controller (MAC)
- AHB Bus Interface
- PHY Interface

The following sections describe the features and functions of each sub-module.

24.3.1 Ethernet Clock Control

Available clock sources are dependent on the interface chosen. The following sections describe the clock control for the various interfaces.

24.3.1.1 PHY Interface

The Ethernet Controller Module and Integrated PHY receive two clock inputs:

- A gated system clock acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SYSCLK frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module. Refer to “System Control” on page 230 for more information on programming SYSCLK and enabling the Ethernet MAC.
- The PHY receives the main oscillator (MOSC) which must be $25\text{ MHz} \pm 50\text{ ppm}$ for proper operation. The MOSC source can be a single-ended source or a crystal. Figure 24-2 on page 1587 shows the clock inputs to the Ethernet Controller Module.

Figure 24-2. Ethernet MAC and PHY Clock Structure

24.3.1.2 MII Interface

Four clock inputs are driven into the Ethernet MAC when the MII configuration is enabled. The clocks are described as follows:

- Gated system clock (SYSCLK): The SYSCLK signal acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SYSCLK frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module. Refer to “System Control” on page 230 for more information on programming SYSCLK and enabling the Ethernet MAC.
- MOSC: A gated version of the MOSC clock is provided as the Precision Time Protocol (PTP) reference clock (PTPREF_CLK). The MOSC clock source can be a single-ended source on the OSC0 pin or a crystal on the OSC0 and OSC1 pins. When advanced timestamping is used and the Precision Timer Protocol (PTP) module has been enabled by setting the PTPCEN bit in the EMACCC register, the MOSC drives PTPREF_CLK. PTPREF_CLK has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. Refer to “IEEE 1588 and Advanced Timestamp Function” on page 1629 for more information.
- EN0RXCK: This clock signal is driven by the external PHY oscillator and is either 2.5 or 25 MHz depending on whether the device is operating at 10 Mbps or 100 Mbps.
- EN0TXCK: This clock signal is driven by the external PHY oscillator and is either 2.5 or 25 MHz depending on whether the device is operating at 10 Mbps or 100 Mbps.

Figure 24-3 on page 1588 depicts the clock inputs for an MII interface.

Figure 24-3. MII Clock Structure

24.3.1.3 RMII Interface

There are three clock sources that interface to the Ethernet MAC in an RMII configuration:

- Gated system clock (SYSCLK): The SYSCLK signal acts as the clock source to the Control and Status registers (CSR) of the Ethernet MAC. The SYSCLK frequency for Run, Sleep and Deep Sleep mode is programmed in the System Control module. Refer to “System Control” on page 230 for more information on programming SYSCLK and enabling the Ethernet MAC.
- MOSC: A gated version of the MOSC clock is provided as the Precision Time Protocol (PTP) reference clock (PTPREF_CLK). The MOSC clock source can be a single-ended source on the OSC0 pin or a crystal on the OSC0 and OSC1 pins. When advanced timestamping is used and the PTP module has been enabled by setting the PTPCEN bit in the **EMACCC** register, the MOSC drives PTPREF_CLK. PTPREF_CLK has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. Refer to “IEEE 1588 and Advanced Timestamp Function” on page 1629 for more information.
- EN0REF_CLK: When using RMII, a 50 MHz external reference clock must drive the EN0REF_CLK input signal and the external PHY. Depending on the configuration of the FES bit in the **Ethernet MAC Configuration (EMACCFG)** register, the reference clock input (EN0REF_CLK) is divided by 20 for 10 Mbps or 2 for 100 Mbps operation and used as the clock for receive and transmit data.

Figure 24-4 on page 1589 depicts the clock inputs to the RMII clock interface.

Figure 24-4. RMII Clock Structure

24.3.2 MII/RMII Interface Signals

The MAC Module has the capability of providing an MII or RMII interface depending on the interface selected in the **Ethernet MAC Peripheral Configuration (EMACPC)** register, at offset 0xFC4. Except for EN0REF_CLK, the signals used for RMII mode are a subset of the MII interface signals. Thus, Table 24-2 on page 1589 details the MII signals that are used in RMII mode and the RMII function to which they correspond. In addition, the GPIO pin they are muxed with is listed.

Table 24-2. MII and RMII Interface Signals

MII Signal	RMII	RMII Standard Name and Function	GPIO
N/A	EN0REF_CLK	REF_CLK: Synchronous clock reference for receive, transmit and control	PM4
EN0TXCK	Not Used	N/A	PG2
EN0TD3	Not Used	N/A	PK7
EN0TD2	Not Used	N/A	PK6
EN0TXD1	EN0TXD1	TXD1: Transmit Data 1	PG5/PS5
EN0TXD0	EN0TXD0	TXD0: Transmit Data 0	PG4/PS4
EN0TXEN	EN0TXEN	TEX_EN: Transmit Enable	PG3/PR7
EN0TXER	Not Used	N/A	PN6
EN0RXCK	Not Used	N/A	PA6
EN0RXD3	Not Used	N/A	PK4
EN0RXD2	Not Used	N/A	PK5
EN0RXD1	EN0RXD1	RXD1: Receive Data 1	PQ6/PT1

Table 24-2. MII and RMII Interface Signals (*continued*)

MII Signal	RMII	RMII Standard Name and Function	GPIO
EN0RXD0	EN0RXD0	RXD0: Receive Data 0	PQ5/PT0
EN0RXDV	EN0RXDV	CRS_DV: Carrier Sense/Receive Data Valid	PG7/PS7
EN0RXER	Not Used	RX_ER: Receive Error ^a	PG6/PS6
EN0COL	Not Used	N/A	PM7
EN0CRS	Not Used	N/A	PM6
EN0MDC	EN0MDC	MDC: Management Data Clock	PB2/PF2

EN0PPS	EN0PPS	Pulse-Per-Second (PPS) Output (optional-this is not a standard RMII signal)	PG0/PJ0/PH5
EN0INTRN	EN0INTRN	Interrupt to Ethernet PHY (optional-this is not a standard RMII signal)	PK4/PP0

a. RX_ER is an optional standard RMII signal and is not used in this device

24.3.3 DMA Controller

The Ethernet Controller's integrated DMA is used to optimize data transfer between the MAC and system SRAM memory. The DMA has independent transmit and receive engines.

The DMA transmit engine transfers data from system memory to the Ethernet TX/RX Controller, while the receive engine transfers data from the RX FIFO to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. Fixed burst lengths of 1, 4, 8, or 16 words are supported along with re-initiation of bursts when retry or burst termination responses occur. For a burst retry, if the remaining address count is greater than 1 and the RIB bit in the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register is clear, then the transfer is resends data with in one continuous burst. When one transfer is left, it is done as a single burst and the transaction is terminated immediately afterward. If the RIB bit in the **EMACDMABUSMOD** register is set, the DMA sends the remaining data in fixed burst sizes of 1, 4, 8, or 16 words.

The application may also choose between solely fixed bursts or mixed bursts by the DMA. If the MB bit is set and the FB bit is clear in the **EMACDMABUSMOD** register, then the DMA uses fixed bursts for burst sizes less than 16 and a full, non-divided burst for lengths greater than 16. Fixed burst lengths allow for more DMA bus arbitration with other masters. Maximum burst transfer lengths can be programmed for both the receive and transmit channels of the DMA through the PBL, RPBL and 8xPBL bit fields in the **EMACDMABUSMOD** register.

The DMA Controller requests a read transfer only when it can accept the received burst data completely. Data read from the bus is always pushed into the DMA without any delay or busy cycles. The DMA requests write transfers only when it has sufficient data to transfer the burst completely. When operating in fixed burst length mode, the DMA interface continues to burst with dummy data until the specified length is completed. The Ethernet controller can be programmed to interrupt the CPU in situations such as Frame Transmit and Receive transfer completion, and other normal/error conditions.

The integrated Ethernet DMA communicates through two data structures:

- Control and Status registers
- Descriptor lists and data buffers.

The DMA writes data frames received by the MAC to the receive buffer in system memory and transfers data frames for transmission from system memory to the MAC. Descriptors that reside in the system memory act as pointers to these buffers.

There are two descriptor lists: one for reception and one for transmission. The base address of each list is written into the **Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)** register at offset 0xC0C and the **Ethernet Mac Transmit Descriptor List Address (EMACTXDLADDR)** register at offset 0xC10, respectively. Three types of descriptor formats are supported in the MAC module:

- Normal (4 words in length)
- Alternate (Used for IEEE1588-2005 Timestamp; 4 words in length, but last two words are used for timestamp values)
- Enhanced (8 words in length; used when optional modules are enabled in application)

These are described in more detail in “Descriptors” on page 1603. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by enabling second address chaining in both the Receive and Transmit descriptors (RDES1[24] and TDES1[24]) for normal descriptor formats. For enhanced descriptors, the second chaining bits are RDES[14] and TDES[20]. The descriptor lists reside in the SRAM memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used at different physical addresses rather than contiguous buffers in memory.

The data buffer also resides in the physical memory space and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data and buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when the end of frame is detected. Data chaining can be enabled or disabled through the descriptors.

Note: The EMAC DMA Controller only has access to internal system SRAM memory.

24.3.3.1 Burst Access

The DMA attempts to execute fixed length Burst transfers if the **FB** bit is set in the **EMACDMABUSMOD** register. The maximum burst length is indicated and limited by the PBL field in the **EMACDMABUSMOD** register. The Receive and Transmit descriptors are always accessed in the maximum possible (limited by PBL) burst-size for the 16- bytes to be read.

The TX DMA initiates a transfer only when there is sufficient space in the FIFO to accommodate the configured burst or remaining bytes of the end of a frame. When the DMA is configured for fixed-length burst, it transfers data using the best combination of fixed burst sizes of 4, 8, or 16 and single transactions. Otherwise when the **FB** bit is clear in the **EMACDMABUSMOD** register, the DMA transfers data as a continuous undefined burst and SINGLE transactions.

The RX DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in RX FIFO or when the end of frame (when it is less than the configured burst length) is detected in the RX FIFO. The DMA indicates the start address and the number of transfers required to the system. When the **FB** bit is set in the **EMACDMABUSMOD** register, then it transfers data using the best combination of fixed burst sizes of 4, 8, or 16 and single transactions. If the end-of frame is reached before the fixed-burst ends, then dummy transfers are performed in order to complete the fixed-burst. Otherwise, if the **FB** bit is clear, the DMA transfers data using INCR (undefined length) and SINGLE transactions. When the DMA is configured for address-aligned transfers, both DMA engines ensure that the first burst transfer on the system bus is less than or

equal to the size of the configured PBL in the **EMACDMABUSMOD** register. Thus, all subsequent transfers start at an address that is aligned to the configured PBL. The DMA can only align the address for burst transfers up to size 16 because only bursts of 16 are supported.

24.3.3.2 Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on the start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers, with address aligned to the bus width and dummy data (old data) in the byte lanes that are not valid. This typically happens during the transfer of the beginning or end of an Ethernet frame. The software driver should discard the dummy bytes based on the start address of the buffer and size of the frame.

For example, if the transmit buffer address is 0x0000.0FF2, and 15 bytes need to be transferred, then the DMA reads five full words from address 0x0000.0FF0, but when transferring data to the TX FIFO, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the TX FIFO, unless it is the end of frame.

If the receive buffer address is 0x0000.0FF2 and 15 bytes of a received frame need to be transferred, then the DMA writes 5 full words from address 0x0000.0FF0. However, the first 2 bytes of first transfer and the last three bytes of the fifth transfer have dummy data. The DMA considers the offset address only if it is the first Receive buffer of the frame. The DMA ignores the offset address and performs full word writes for the middle and the last Receive buffer of the frame.

24.3.3.3 Buffer Size Calculations

The DMA does not update the size fields in the Transmit and Receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations. The TX DMA transfers the exact number of bytes (indicated by buffer size field of TDES1) to the MAC. If a descriptor is marked as first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame (SOF). If a descriptor is marked as last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of frame (EOF).

The RX DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the RX/TX Controller. If a descriptor is not marked as last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The Receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to the data width of 32-bit system bus, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1,024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the Receive descriptor to have a 0x1002 offset. The Receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

24.3.3.4 DMA Arbiter

The arbiter inside the DMA module performs the arbitration between the Transmit and Receive channel accesses. The DMA can be configured to arbitrate in a round-robin or fixed-priority configuration. When the DA bit of the **EMACDMABUSMOD** register is clear, the DMA arbiter allocates the data bus in the ratio set by the PR bit field of the **EMACDMABUSMOD** register when both the TX and RX DMA request access at the same time. When the DA bit is set, the RX DMA always has priority over the TX DMA for data access by default. However if the TXPR bit of the **EMACDMABUSMOD** register is also set, then the TX DMA always gets priority over the RX DMA.

24.3.3.5 DMA Transmission Operation

The following sections describe the modes of the transmit operation.

TX DMA Default Operation

The TX DMA engine in default mode, operates as follows:

1. The CPU configures the transmit descriptor (TDES0-TDES3) and sets the OWN bit (TDES0[31]) after setting up the corresponding data buffers with the Ethernet frame.
2. When the ST bit of the **Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)** register, offset 0xC18, is set the DMA enters the RUN state.
3. While in RUN state, the DMA polls the Transmit Descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the CPU (TDES0[31]=0), or if an error condition occurs, transmission is suspended and both the Transmit Buffer Unavailable (TU) bit and the Normal Interrupt Summary (NIS) bit are set in the **Ethernet MAC DMA Interrupt Status (EMACDMARIS)** register, offset 0xC14. The transmit engine the proceeds to Step 9.
4. If the acquired descriptor is flagged as owned by the DMA (TDES0[31]=1), the DMA decodes the transmit data buffer address from the acquired descriptor.
5. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
6. The DMA fetches the transmit data from system memory and transfers the data to the TX/RX Controller for transmission.
7. If the Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3, 4, and 5 are repeated until the end of the Ethernet frame data is transferred to the TX/RX Controller.
8. When frame transmission is complete, if IEEE 1588 timestamping was enabled for the frame (as indicated in the transmit status) the timestamp value is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. For Enhanced descriptors, the timestamp value is written into TDES6 and TDES7. The status information is then written to this transmit descriptor (TDES0). Because the OWN bit is cleared during this step, the CPU now owns this descriptor. If timestamping was not enabled for this frame, the DMA does not alter the contents of TDES2/TDES3 or TDES6/TDES7 depending on the descriptor configuration chosen.
9. The Transmit Interrupt (TI) bit is set in the **EMACDMARIS** register after transmission completion of a frame that has Interrupt on Completion set in its last descriptor. The Interrupt on Completion

bit resides in TDES[31] for normal descriptors and TDES0[30] for alternate descriptors. The DMA engine then returns to Step 3.

10. In the suspend state, the DMA tries to reacquire the descriptor (and thereby return to Step 3) when it receives a transmit poll demand in the **Ethernet MAC Transmit Poll Demand (EMACTXPOLLD)** register, offset 0xC04, and the Underflow Interrupt Status (UNF) bit is cleared in the **EMACDMARIS** register. If the CPU stopped the DMA by clearing the ST bit of the **EMACDMAOPMODE** register, the DMA enters the STOP state.

Figure 24-5 on page 1595 shows the flow for the TX DMA default operation.

Figure 24-5. TX DMA Default Operation Using Normal Descriptors

If using Enhanced Descriptors, TDES2 and TDES3 are replaced with TDES6 and TDES7.

TX DMA OSF Mode Operation

While in the RUN state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first if the OSF bit of the **EMACDMAOPMODE** register is set. As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information.

In Operate on Second Frame (OSF) mode, the RUN state TX DMA operates in the following sequence:

1. The DMA operates as described in Steps 1 to 6 (see page 1593).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into SUSPEND mode and skips to 7.
4. The DMA fetches the Transmit frame from system memory and transfers the frame until the end of the frame data is reached. It closes the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the previous frame's frame transmission status and times tamp. When the status is available, the DMA writes the timestamp to TDES2 and TDES3, if such timestamp was captured (as indicated by a status bit). If enhanced descriptors are being used, this information is written in TDES6 and TDES7. The DMA then writes the status, with a cleared OWN bit, to the corresponding TDES0, thus closing the descriptor. If timestamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3 (or TDES6/7 for enhanced descriptors).
6. If enabled, the Transmit interrupt (TI) bit is set in the **EMACDMARIS** register, the DMA fetches the next descriptor and then proceeds to 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into SUSPEND mode.
7. In SUSPEND mode, if a pending status and timestamp are received, the DMA writes the timestamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. For enhanced descriptor use, the timestamp is written to TDES6 and TDES7 and the status is written to TDES0. It then sets relevant interrupts and returns to SUSPEND mode.
8. The DMA can exit SUSPEND mode and enter the RUN state only after receiving the Transmit Poll demand in the **EMACTXPOLLD** register.

Note: The DMA fetches the next descriptor in advance before closing the current descriptor. Therefore, the descriptor chain should have more than two different descriptors for correct and proper operation.

Figure 24-6 on page 1597 shows the flow for the TX DMA Operate-On-Second-Frame (OSF) operation.

Figure 24-6. TX DMA OSF Mode Operation Using Normal Descriptors

If using Enhanced Descriptors, TDES2 and TDES3 are replaced with TDES6 and TDES7.

Transmit Frame Processing

The TX DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and Frame Check Sequence (FCS) fields. The Destination Address (DA), Source Address (SA), and Type/Length fields must contain valid data. If the Transmit Descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes. Frames can be data-chained and can span several buffers.

Frames must be delimited by the First Segment Descriptor and the Last Segment Descriptor, respectively. For normal descriptors, the First Descriptor bit is located at TDES1[29] and the Last Descriptor is located at TDES1[30]. For Enhanced descriptor format, the First Segment Descriptor bit is located in TDES0[28] and the Last Segment Descriptor bit is located in TDES0[29].

As transmission starts, the First Descriptor must have TDES1[29]/TDES0[28] set. When this occurs, frame data transfers from the host memory buffer to the TX FIFO. Concurrently, if the current frame has the Last Segment Descriptor (TDES1[30]/TDES0[29]) clear, the transmit process attempts to acquire the next descriptor. The transmit process expects this descriptor to have TDES1[29]/TDES0[28] clear. If TDES1[30]/TDES0[29] is clear, it indicates an intermediary buffer. If TDES1[30]/TDES0[29] is set, it indicates the last buffer of the frame. After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor word of the descriptor that has the last segment bit set in Transmit Descriptor. At this time, if Interrupt on Completion (IC) bit is set, the TI bit in the **EMACDMARIS** register is set, the next descriptor is fetched and the process repeats.

The actual frame transmission begins after the TX FIFO has reached either the transmit threshold as configured by the TTC bit field of the **EMACDMAOPMODE** register, or a full frame is contained in the TX FIFO. To wait until there is a full frame in the TX FIFO the TSF bit in the **EMACDMAOPMODE** register must be set. Descriptors are released (OWN bit in the TDES0[31] cleared) when the DMA finishes transferring the frame.

Note: To ensure proper transmission of a frame and the next frame, the transmit descriptor that has the Last Descriptor bit (TDES1[30]/TDES0[29]) set, must specify a non-zero buffer size.

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the CPU (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command.
- A frame transmission is aborted when a transmit error because of underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set.

If the DMA goes into SUSPEND state because of the first condition, then both the Normal Interrupt Summary (NIS) bit and the Transmit Buffer Unavailable (TU) bit are set in the **EMACDMARIS** register. If the second condition occurs, the Abnormal Interrupt Summary (AIS) bit and the Transmit Underflow (UNF) bit of the **EMACDMARIS** register are set and the information is written to Transmit Descriptor 0, causing the suspension.

In both cases, the position in the Transmit list is retained . The retained position is that of the descriptor following the last descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension case.

24.3.3.6 DMA Receive Operation

The following section describes the receive operation process.

Default Receive Operation

The RX DMA engine's reception sequence is as follows:

1. The host sets up receive descriptors (RDES0-RDES3) and sets the OWN bit (RDES0[31]).
2. When the SR bit of the **EMACDMAOPMODE** register is set, the DMA enters the RUN state. While in the RUN state, the DMA polls the Receive Descriptor list, attempting to acquire free

descriptors. If the fetched descriptor is not free (is owned by the CPU), the DMA enters the Suspend state and jumps to Step 9.

3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the RX DMA engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 7. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error (DE) bit in the RDES0 (unless flushing is disabled through the DFF bit in the **EMACDMAOPMODE** register). The DMA closes the current descriptor (clears the OWN bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value. If flushing is not disabled, then the DMA would mark it as the last descriptor. In either case, the DMA proceeds to Step 8. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 4.
7. If IEEE 1588 timestamping is enabled, the DMA writes the timestamp to the current descriptor's RDES[2] and RDES[3] (or RDES[6] and RDES[7] if using alternate descriptors). It then takes the receive frame's status and writes the status word to the current descriptor's RDES0, with the OWN bit cleared and the Last Segment (LS) bit set. If the host stopped the RX DMA by clearing the SR bit of the **EMACDMAOPMODE** register, DMA goes to the STOP state, otherwise the RX DMA proceeds to Step 8.
8. The RX DMA engine checks the last descriptor's OWN bit. If the CPU owns the descriptor (OWN bit is 0), the RU bit of the **EMACDMARIS** register is set and the DMA RX engine enters the SUSPEND state (.). If the DMA owns the descriptor, the engine returns to Step 4 and awaits the next frame.
9. Before the RX DMA engine enters the SUSPEND state, partial frames are flushed from the RX FIFO. Flushing can be controlled through the DFF bit of the **EMACDMAOPMODE** register.
10. The RX DMA enters the STOP state if the CPU has cleared the SR bit of the **EMACDMAOPMODE** register. Otherwise, it exits the SUSPEND state when a Receive Poll Demand is given or the start of the next frame is available from the RX FIFO. The DMA engine proceeds to Step 2 and re-fetches the next descriptor.

The DMA does not acknowledge accepting status from the TX/RX Controller until it has completed the timestamp write-back and is ready to perform status write-back to the descriptor.

If software has enabled timestamping through the **Ethernet MAC Timestamp Control (EMACTIMSTCTRL)** register, offset 0x700, when a valid timestamp is not available for the frame (for example, because the receive FIFO was full before the timestamp could be written to it), the DMA writes all-ones to RDES2 and RDES3 (or RDES[6] and RDES[7] if using alternate descriptors). Otherwise if timestamping is not enabled, the RDES[2]/RDES[6] and RDES[3]/RDES[7] remain unchanged.

Figure 24-7 on page 1600 shows the flow of a RX DMA Operation.

Figure 24-7. RX DMA Operation Flow

If using Enhanced Descriptors, TDES2 and TDES3 are replaced with TDES6 and TDES7.

Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- The **SR** bit of the **EMACDMAOPMODE** register has been set immediately after being placed in the RUN state.
- The data buffer or current descriptor is full before the frame ends for the current transfer.
- The controller has completed frame reception, but the current receive descriptor is not yet closed.
- The receive process has been suspended because of a host-owned buffer (**RDES0[31]**=0) and a new frame is received.
- A receive poll demand has been issued.

Receive Frame Processing

The MAC transfers the received frames to the system memory only when the frame passes the address filter and the frame size is greater than or equal to configurable threshold bytes set for the RX FIFO, or when the complete frame is written to the RX FIFO in store-and-forward mode.

If the frame fails the address filtering, it is dropped in the MAC block unless the Receive All (**RA**) bit is set in the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)**, offset 0x004. If the **RA** bit is set, then the MAC passes all received frames. Frames that are shorter than 64 bytes, because of collision or premature termination, can be removed from the RX FIFO if the **DFF** bit is clear in the **EMACDMAOPMODE** register.

After 64 bytes have been received, the TX/RX Controller requests the DMA block to begin transferring the frame data to the receive buffer pointed by the current descriptor. The DMA sets the First Descriptor (**RDES0[9]**) bit to delimit the frame after the DMA Interface becomes ready to receive a data transfer (if DMA is not fetching transmit data from the system memory). The descriptors are released when the OWN (**RDES0[31]**) bit is reset to 0, either as the data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (**RDES0[8]**) and First Descriptor (**RDES0[9]**) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (**RDES0[8]**) bit, and releases the **RDES0** status bits in the previous frame descriptor. Then the DMA sets the **RI** bit of the **EMACDMARIS** register. The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs, the receive process sets the **RU** bit of the **EMACDMARIS** and enters the SUSPEND state. The position in the receive list is retained.

Receive Process Suspend

If a new receive frame arrives while the receive process is in SUSPEND state, the DMA refetches the current descriptor in the system memory. If the descriptor is now owned by the DMA, the receive process re-enters the RUN state and starts frame reception. If the descriptor is still owned by the CPU, by default, the DMA discards the current frame at the top of the RX FIFO and increments the missed frame counter. If more than one frame is stored in the RX FIFO, the process repeats. The discarding or flushing of the frame at the top of the RX FIFO can be prevented by disabling flushing through the **DFF** bit of the **EMACDMAOPMODE** register. In such conditions, the receive process sets the Receive Buffer Unavailable (**RU**) status and returns to the SUSPEND state.

24.3.3.7 DMA Interrupts

Interrupts can be generated as a result of various transfer events. The current status of interrupts can be read from the **EMACDMARIS** register and are enabled to trigger an interrupt through the programming of the **Ethernet MAC DMA Interrupt Mask (EMACDMAIM)** register. There are two groups of transfer event interrupts: Normal and Abnormal. The following lists the two groups:

- Normal Interrupts:
 - Transmit Interrupt (TI, bit 0): Indicates that frame transmission is complete.
 - Transmit Buffer Unavailable (TU, bit 2): Indicates the CPU owns the next descriptor in the transmit list and the DMA cannot acquire it.
 - Receive Interrupt (RI, bit 6): Indicates the frame reception is complete.
 - Early Receive Interrupt (ERI, bit 14): Indicates the DMA has filled the first half of the data buffer of the packet

- Abnormal Interrupts:
 - Transmit Process Stopped (TPS, bit 1): Indicates transmission is stopped.,
 - Transmit Jabber Timeout (TJT, bit 3): Indicates the Transmit Jabber Timer expired.
 - Receive FIFO Overflow (OVF, bit 4): Indicates the receive buffer had an overflow during frame reception.
 - Transmit Underflow (UNF, bit 5): Indicates the transmit buffer had an underflow during frame transmission.
 - Receive Buffer Unavailable (RU, bit): Indicates the CPU owns the next descriptor in the receive list and the DMA cannot acquire it.
 - Receive Process Stopped (RPS, bit 8): Indicates the receive process entered the STOP state.
 - Receive Watchdog Timeout (RWT, bit 9): Indicates a frame length greater than 2 KB is received (10,240 when Jumbo Frame is enabled)
 - Early Transmit Interrupt (ETI, bit 10): Indicates a frame to be transmitted is fully transferred to the TX FIFO.
 - Fatal Bus Error (FBI, bit 13): Indicates a bus error occurred.

Any of the interrupts in the Normal Interrupt group that are enabled in the **EMACDMAIM** register are ORed together to create the Normal Interrupt Summary (NIS) bit in the **EMACDMARIS** register. Any of the interrupts in the Abnormal Interrupt group that are enabled in the **EMACDMAIM** register are ORed together to create the Abnormal Interrupt Summary (AIS) bit in the **EMACDMARIS** register. Interrupts are cleared by writing a 1 to the corresponding bit position in the **EMACDMARIS** register. When all enabled interrupts within a group are cleared, the corresponding summary bit is cleared.

Interrupts are not queued and if the interrupt event occurs again before the driver has responded to it, no additional interrupts are generated. An interrupt is only generated once for simultaneous, multiple events. The driver must read the **EMACDMARIS** register for the cause of the interrupt.

The **Ethernet MAC Receive Interrupt Watchdog Timer (EMACRXINTWDT)** register, offset 0xC24 can be used to control the Receive Interrupt (RI) assertion. If the RDES1[31] bit (Receive Interrupt) bit has not been set in the receive descriptor and the **EMACRXINTWDT** register is programmed with a non-zero value, it gets activated as soon as the RX DMA completes a transfer of a received frame to system memory without asserting the receive interrupt. When this counter runs out as per the programmed value, the RI bit is set in the **EMACDMARIS** register and the interrupt is asserted

if the corresponding RI bit is enabled in the **EMACDMAIM** register. This counter gets disabled before it runs out if a frame is transferred to memory and the RI bit is set because it is enabled for that descriptor.

24.3.3.8 DMA Bus Error

If an internal bus error occurs during a DMA transfer, the fatal bus error (FBI) interrupt is set in the **EMACDMARIS** register and the Access Error status (AE) bit field in the **EMACDMARIS** register indicates the type of error that caused the bus error. The DMA controller can resume operation only after soft resetting the Ethernet MAC and the re-initializing the DMA.

24.3.4 Descriptors

The descriptor that the DMA uses is normally constructed of four words. When using the advanced timestamp feature, or source address or VLAN insertion, the enhanced descriptor should be enabled by setting the ATDS bit in the **EMACDMABUSMOD** register. This allows the descriptor to expand to eight words for storing additional information important to these enhanced features.

Figure 24-8 on page 1603 shows the normal receive and transmit descriptor configuration:

Figure 24-8. Normal Receive and Transmit Descriptor Configuration

24.3.4.1 Transmit Descriptor

The MAC requires at least one descriptor for a transmit frame. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit frame basis.

Transmit Descriptor 0 (TDES0) contains the transmitted frame status and the descriptor ownership information. Table 24-3 on page 1603 shows the information stored in TDES0.

Table 24-3. Transmit Descriptor 0 (TDES0)

Bit	Description
31	OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are empty. The ownership bit of the First Descriptor of the frame should be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.
30:18	Reserved

Table 24-3. Transmit Descriptor 0 (TDES0) (continued)

Bit	Description
17	TSS:TX Timestamp This status bit indicates that a timestamp has been captured for the corresponding transmit frame. When this bit is set, TDES2 and TDES3 have timestamp values that were captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30]) in a descriptor is set.
16	IHE: IP Header Error When set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when TX Checksum Offload is enabled. Otherwise, it is reserved. If the Checksum Offload Engine detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.
15	ES: Error Summary Indicates the logical OR of the following bits: <ul style="list-style-type: none"> ■ TDES0[16]: IP Header Error ■ TDES0[14]: Jabber Timeout ■ TDES0[13]: Frame Flush ■ TDES0[12]: Payload Checksum Error ■ TDES0[11]: Loss of Carrier ■ TDES0[10]: No Carrier ■ TDES0[9]: Late Collision ■ TDES0[8]: Excessive Collision ■ TDES0[2]: Excessive Deferral ■ TDES0[1]: Underflow error
14	JT: Jabber Timeout When set, this bit indicates that the MAC transmitter has experienced a jabber timeout. This bit can only be set when the JD bit of the EMACCFG register is clear (Jabber timeout enabled).
13	FF: Frame Flushed When set, this bit indicates that the DMA flushed the frame because of a software flush command given by the CPU.
12	PCE: Payload Checksum Error This bit, when set, indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the IP Header's Payload Length field, or the TX/RX Controller starting to forward the frame to the MAC transmitter in the store-and-forward mode without the checksum having been calculated yet. This second error condition only occurs when the TX FIFO depth is less than the length of the Ethernet frame being transmitted and to avoid deadlock, the TX/RX Controller starts forwarding the frame when the TX FIFO is full, even in the store-and-forward mode.
11	LC: Loss of Carrier When set, this bit indicates that Loss of Carrier occurred during frame transmission. This is valid only for the frames transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC: No Carrier When set, this bit indicates that the carrier sense signal from the PHY was not asserted during transmission.
9	LC: Late Collision When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times including Preamble in MII Mode). Not valid if Underflow Error (bit 1) is set.

Table 24-3. Transmit Descriptor 0 (TDES0) (continued)

Bit	Description
8	Excessive Collision When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the Disable Retry (DR) bit in EMACCFG register is set, this bit is set after the first collision and the transmission of the frame is aborted.
7	VF: VLAN Frame When set, this bit indicates that the transmitted frame was a VLAN-type frame.
6:3	CC: Collision Count This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collision bit (TDES0[8]) is set.
2	ED: Excessive Deferral When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times when Jumbo Frame is enabled). This bit is dependent on the Deferral Check (DC) bit being enabled in the EMACCFG register.
1	UF: Underflow Error When set, this bit indicates that the MAC aborted the frame because the data arrived late from system memory. Underflow Error indicates that the DMA encountered an empty Transmit Buffer while transmitting the frame. The transmission process enters the suspended state and sets both Transmit Underflow (UNF) and Transmit Interrupt (TI) bit in the EMACDMARIS register.
0	DB: Deferred Bit When set, this bit indicates that the MAC defers before transmission because of the presence of a carrier. This bit is only valid in half-duplex mode.

TDES1 contains the buffer sizes and other bits which control the descriptor chain or ring and the frame being transferred.

Table 24-4. Transmit Descriptor 1 (TDES1)

Bit	Description
31	IC: Interrupt on Completion When set this bit sets the Transmit Interrupt (TI) bit in the EMACDMARIS register when the frame contained in this descriptor has been transmitted.
30	LS: Last Segment When set, this bit indicates that the buffer contains the last segment of the frame. When this bit is set, the TBS1 or TBS2 field should have a non-zero value.
29	FS: First Segment When set, this bit indicates that the buffer contains the first segment of a frame.

Table 24-4. Transmit Descriptor 1 (TDES1) (continued)

Bit	Description
28:27	<p>CIC: Checksum Insertion Control These bits control the insertion of checksums in Ethernet frames that encapsulate TCP, UDP, or ICMP over IPv4 or IPv6:</p> <ul style="list-style-type: none"> ■ 0x0: Do nothing . Checksum Engine bypassed. ■ 0x1: Insert IPv4 header checksum. Use this value to insert IPv4 header checksum when the frame encapsulates an IPv4 datagram. ■ 0x2: Insert TCP/UDP/ICMP checksum. The checksum is calculated over the TCP, UDP, or ICMP segment only and the TCP, UDP, or ICMP pseudo-header checksum is assumed to be present in the corresponding input frame's Checksum field. An IPv4 header checksum is also inserted if the encapsulated datagram conforms to IPv4. ■ 0x3: Insert a TCP/UDP/ICMP checksum that is fully calculated in this engine. The TCP, UDP, or ICMP pseudo-header is included in the checksum calculation, and the input frame's corresponding Checksum field has an all-zero value. An IPv4 Header checksum is also inserted if the encapsulated datagram conforms to IPv4. <p>The Checksum engine detects whether the TCP, UDP, or ICMP segment is encapsulated in IPv4 or IPv6 and processes its data accordingly.</p>
26	DC: Disable CRC When set, the MAC does not append the Cyclic Redundancy Check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES1[29]) is set.
25	TER: Transmit End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.
24	TCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES1[24] is set, TBS2 (TDES1[21–11]) are don't care values. TDES1[25] takes precedence over TDES1[24].
23	DP: Disable Padding When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes and the CRC field is added despite the state of the DC (TDES1[26]) bit. This is valid only when the first segment (TDES1[29]) is set.
22	TTSE: Transmit Timestamp Enable When set, this bit enables IEEE1588 hardware timestamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES1[29]) is set.
21:11	TBS2: Transmit Buffer 2 Size These bits indicate the Second Data Buffer in bytes. This field is not valid if TDES1[24] is set.
10:0	TBS1: Transmit Buffer 1 Size These bits indicate the First Data Buffer byte size. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of TCH (Bit 24).

TDES2 contains the address pointer to the first buffer of the descriptor.

Table 24-5. Transmit Descriptor 2 (TDES2)

Bit	Description
31:0	<p>Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment.</p> <p>Note: The buffer address must be in SRAM.</p>

TDES3 contains the address pointer either to the second buffer of the descriptor or the next descriptor.

Table 24-6. Transmit Descriptor 3 (TDES3)

Bit	Description
31:0	Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the 32-bit bus when TDES1[24] is set.

24.3.4.2 Receive Descriptor

The DMA requires at least two descriptors when receiving a frame. The DMA always attempts to acquire an extra descriptor in anticipation of an incoming frame. Before the DMA closes a descriptor, it attempts to acquire the next descriptor even if no frames are received. In a single descriptor (receive) system, the subsystem generates a descriptor error if the receive buffer is unable to accommodate the incoming frame and the next descriptor is not owned by the DMA.

RDES0 contains the received frame status, the frame length, and the descriptor ownership information.

Table 24-7. Receive Descriptor 0 (RDES0)

Bit	Description
31	OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	AFM: Destination Address Filter Fail When set, this bit indicates a frame failed in the DA filter in the MAC.
29:16	FL: Frame Length These bits indicate the byte length of the received frame that was transferred to the system memory. This field is valid when the Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or the Overflow Error bit is clear. When the Last Descriptor bit is not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. The inclusion of CRC length in the frame length depends on the settings of CRC configuration bits, ACS and CST in the EMACCFG register.
15	ES: Error Summary Indicates the logical OR of the following bits: <ul style="list-style-type: none">■ RDES0[14]: Descriptor Error■ RDES0[11]: Overflow Error■ RDES0[7]: IPC Checksum (Type 2) or Giant Frame■ RDES0[6]: Late Collision■ RDES0[4]: Watchdog Timeout■ RDES0[3]: Receive Error■ RDES0[1]: CRC Error■ RDES0[0]: Payload Checksum error This field is valid only when the Last Descriptor (RDES0[8]) is set.

Table 24-7. Receive Descriptor 0 (RDES0) (continued)

Bit	Description
14	DE: Descriptor Error When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.
13	SAF: Source Address Filter Fail When set, this bit indicates that the SA field of frame failed the SA Filter in the MAC.
12	LE: Length Error When set, this bit indicates that the actual length of the frame received and the Length/ Type field do not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset. Length error status is not valid when CRC error is present.
11	OE: Overflow Error When set, this bit indicates that the received frame is damaged because of buffer overflow in RX FIFO. Note: This bit is set only when the DMA transfers a partial frame to the application. This happens only when the RX FIFO is operating in the threshold mode. In the store-and-forward mode, all partial frames are dropped completely in RX FIFO.
10	VLAN: VLAN Tag When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the MAC. The VLAN tagging depends on checking VLAN fields of the received frame configured in the Ethernet MAC VLAN Tag (EMACVLANTG) register, offset 0x01C
9	FS: First Descriptor When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.
8	LS: Last Descriptor When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame.
7	IPC Checksum Error or Giant Frame When set, this bit indicates an error in the IPv4 or IPv6 header. This error can be because of inconsistent Ethernet Type field and IP header Version field values, a header checksum mismatch in IPv4, or an Ethernet frame lacking the expected number of IP header bytes.
6	LC: Late Collision When set, this bit indicates that a late collision has occurred while receiving the frame in half-duplex mode.
5	FT: Frame Type When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 1,536). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames which are less than 14 bytes. In addition when the IPC bit is set in the EMACCFG register, this bit conveys different information. See Table 24-8 on page 1609.
4	RWT: Receive Watchdog Timeout When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.
3	RE: Receive Error When set, this bit indicates that an error occurred during fame reception.
2	DE: Dribble Bit Error When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.
1	CE: CRC Error When set this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set..

Table 24-7. Receive Descriptor 0 (RDES0) (continued)

Bit	Description
0	RX MAC Address or Payload Checksum Error When set, this bit indicates that the Ethernet MAC Address n (EMACADDRXH/L) registers value matched the frame's DA field. When reset, this bit indicates that the Ethernet MAC Address 0 H/L (EMACADDR0H/L) register value matched the DA field. This bit is invalid when Bit 30 is set. If the Full Checksum Offload Engine is enabled, this bit, when set, indicates that the received number of payload bytes does not match the value indicated in the Length field of the encapsulated IPv4 or IPv6 datagram in the received Ethernet frame

Table Table 24-8 on page 1609 shows the frame information conveyed in bits 7, 5, and 0 of RDES0 when the Checksum Offload Engine is enabled and disabled through the **IPC** bit in the **EMACCFG** register.

Table 24-8. RDES0 Checksum Offload bits

Bit 5: Frame Type	Bit 7: IPC Checksum Error	Bit 0: Payload Checksum Error	IPC bit value in EMACCFG register	Frame Status
0	0	0	X	IEEE 802.3 Type frame (Length field value is less than 1,536). This status definition is valid even when the Checksum Offload engine is disabled.
1	0	0	0	IPv4/IPv6 Type frame in which no checksum error is detected.
1	0	0	1	The frame is an IEEE 802.3 Type frame (Length field value is greater than or equal to 1,536).
1	0	1	1	IPv4/IPv6 Type frame with a payload checksum error detected
1	1	1	1	IPv4/IPv6 Type frame with both IP header and payload checksum errors detected
0	0	1	1	IPv4/IPv6 Type frame with no IP header checksum error and the payload check bypassed, due to an unsupported payload
0	1	1	1	A Type frame that is neither IPv4 or IPv6 (the Checksum Offload engine bypasses checksum completely.)
0	1	0	X	Reserved

RDES1 contains the buffer sizes and other bits that control the descriptor chain or ring.

Table 24-9. Receive Descriptor 1 (RDES1)

Bit	Description
31	Disable Interrupt on Completion When set this bit prevents the setting of the bit Receive Interrupt (RI) bit in the EMACDMARIS register and prevents the receive interrupt from being asserted.
30:26	Reserved
25	RER: Receive End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a Descriptor Ring.
24	RCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When RDES1[24] is set, RBS2 (RDES1[21-11]) is a don't care value. RDES1[25] takes precedence over RDES1[24].
23:22	Reserved

Table 24-9. Receive Descriptor 1 (RDES1) (continued)

Bit	Description
21:11	RBS2: Receive Buffer 2 Size These bits indicate the Second Data Buffer in bytes. This field is not valid if RDES1[24] is set.
10:0	RBS1: Receive Buffer 1 Size These bits indicate the First Data Buffer byte size. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 24).

RDES2 contains the address pointer to the first data buffer in the descriptor.

Table 24-10. Receive Descriptor 2 (RDES2)

Bit	Description
31:0	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of the frame. The DMA performs a write operation with the RDES2[3:0, 2:0, or 1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3:0, 2:0, or 1:0], corresponding to bus width of 128, 64, or 32, if the address pointer is to a buffer where the middle or last part of the frame is stored.

Table 24-11. Receive Descriptor 3 (RDES3)

Bit	Description
31:0	Buffer 2 Address Pointer (Next Descriptor Address) These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[1:0] = 0, corresponding to a bus width of 32.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[1:0], if the address pointer is to a buffer where the middle or last part of the frame is stored.

24.3.4.3 IEEE 1588-2005 Timestamp Descriptor Format

If the IEEE 1588-2005 timestamp feature is enabled, the DES2 and DES3 descriptor fields take on a different meaning when the DMA closes the descriptor. The DMA updates the DES2 and DES3 with the timestamp value in these two descriptor fields before clearing the OWN bit in DES0. When the IEEE1588-2005 timestamping is enabled, the DES2 and DES3 fields are updated with the timestamp value. DES2 is updated with the sub-second field (also called Timestamp Low (TSL)) value and the DES3 field is updated with the seconds field (also called Timestamp High (TSH)).

The TDES2 and TDES3 field descriptions for timestamping enabled are shown in Table 24-12 on page 1610 and Table 24-13 on page 1611. In addition, bit 17 of the TDES0 descriptor and bit 22 of the TDES1 descriptor are valid during timestamping.

Table 24-12. Transmit Descriptor 2 (TDES2) with 1588-2005 Timestamping Enabled

Bit	Description
31:0	TTSL: Transmit Frame Timestamp Low This field is updated by DMA with the least significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment control bit (LS) in the descriptor is set.

Table 24-13. Transmit Descriptor 3 (TDES3) with 1588-2005 Timestamping Enabled

Bit	Description
31:0	<p>TTSH: Transmit Frame Timestamp High</p> <p>This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment control bit (LS) in the descriptor is set.</p>

The RDES2 and RDES3 field descriptions for timestamping enabled are shown in Table 24-14 on page 1611 and Table 24-15 on page 1611. Note that when the timestamp feature is disabled, the DMA does not update the RDES2 and RDES2 fields of the descriptor before closing RDES0.

Table 24-14. Receive Descriptor 2 (RDES2) with 1588-2005 Timestamping Enabled

Bit	Description
31:0	<p>RTSL: Receive Frame Timestamp Low</p> <p>The DMA updates this field with the least significant 32 bits of the timestamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]). When this field and the RTSH field in RDES3 show an all-ones value, the timestamp must be treated as corrupt.</p>

Table 24-15. Receive Descriptor 3 (RDES3) with 1588-2005 Timestamping Enabled

Bit	Description
31:0	<p>RTSH: Receive Frame Timestamp High</p> <p>The DMA updates this field with the most significant 32 bits of the timestamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8]). When this field and RDES2's RTSL field show all-ones values, the timestamp must be treated as corrupt.</p>

24.3.4.4 Enhanced Descriptors

When the IEEE 1588-2008 Advanced Timestamp feature or the SA, VLAN or CRC Insertion feature is enabled, the descriptor structure is eight words instead of four words. If enhanced descriptors are used, then the DES6 and DES7 fields for receive and transmit contain the timestamp high and low data. In addition, the control and status bits in DES0 and DES1 are changed.

Enhanced Transmit Descriptor

Figure 24-9 on page 1612 shows the enhanced transmit descriptor. Software must program the control bits TDES0[31:18] during descriptor initialization. When the DMA updates the descriptor, it writes back all the control bits to their initialized value, clears the OWN bit and updates the status bits.

With advanced timestamp support, the snapshot of the timestamp to be taken can be enabled for a given frame by setting Bit 25 (TTSE) of TDES0. When the descriptor is closed (that is, when the OWN bit is cleared), the timestamp is written into TDES6 and TDES7.

Note: When Advanced Timestamp feature is enabled, software should set the ATDS bit of the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register, offset 0xC00, so that the DMA operates with extended descriptor size. When this control bit is reset, the TDES4-TDES7 descriptor space is not valid.

Figure 24-9. Enhanced Transmit Descriptor Structure

The following tables define the Enhanced Transmit Descriptors.

Table 24-16. Enhanced Transmit Descriptor 0 (TDES0)

Bit	Description
31	OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are empty. The ownership bit of the First Descriptor of the frame should be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit.
30	IC: Interrupt on Completion When set, this bit sets the Transmit Interrupt (Register 5[0]) after the present frame has been transmitted.
29	LS: Last Segment When set, this bit indicates that the buffer contains the last segment of the frame. When this bit is set, the TBS1 or TBS2 field in TDES1 should have a non-zero value.
28	FS: First Segment When set, this bit indicates that the buffer contains the first segment of a frame.

Table 24-16. Enhanced Transmit Descriptor 0 (TDES0) (continued)

Bit	Description
27	DC: Disable CRC When this bit is set, the MAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set.
26	DP: Disable Pad When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set.
25	TTSE: Transmit Timestamp Enable This status bit indicates that a timestamp has been captured for the corresponding transmit frame. When set, this bit enables IEEE1588 hardware timestamping for the transmit frame referenced by the descriptor. This bit is only valid when the First Segment Control bit (TDES0[28]) is set.
24	CRCR: CRC Replacement Control When set, the MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The CPU should ensure that the CRC bytes are present in the frame being transferred from the Transmit Buffer. CRC replacement is done only when Bit 27 (DC) is set to 1.
23:22	CIC: Checksum Insertion Control These bits control the checksum calculation and insertion. The following list describes the bit encoding: <ul style="list-style-type: none"> ■ 0x0= Checksum Insertion Disabled ■ 0x1= Only IP header checksum calculation and insertion are enabled. ■ 0x2=IP header checksum and payload checksum calculation and insertion are enabled, but pseudoheader checksum is not calculated in hardware. ■ 0x3= IP Header checksum and payload checksum calculation and insertion are enabled, and pseudoheader checksum is calculated in hardware. This field is valid when the First Segment control bit (TDES0[28]) is set.
21	TER: Transmit End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.
20	TCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a “don’t care”? value. TDES0[21] takes precedence over TDES0[20].
19:18	VLIC: VLAN Insertion Control When set, these bits request the MAC to perform VLAN tagging or untagging before transmitting the frames. If the frame is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The values of this field are as follows: <ul style="list-style-type: none"> ■ 0x0= Do not add a VLAN tag ■ 0x1= Remove the VLAN tag from the frames before transmission. ■ 0x2= Insert a VLAN tag with the tag value programmed in the Ethernet MAC VLAN Tag Inclusion or Replacement (EMACVLNINCREP) register, offset 0x584. ■ 0x3= Replace the VLAN tag in frame with the tag value programmed in the EMACVLNINCREP register. This field is valid when the First Segment control bit (TDES0[28]) is set.
17	TTSS:TX Timestamp This status bit indicates that a timestamp has been captured for the corresponding transmit frame. When this bit is set, TDES6 and TDES7 have timestamp values that were captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES0[29]) in a descriptor is set.

Table 24-16. Enhanced Transmit Descriptor 0 (TDES0) (continued)

Bit	Description
16	IHE: IP Header Error When set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when TX Checksum Offload is enabled. Otherwise, it is reserved. If the Checksum Offload Engine detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.
15	ES: Error Summary Indicates the logical OR of the following bits: <ul style="list-style-type: none">■ TDES0[16]: IP Header Error■ TDES0[14]: Jabber Timeout■ TDES0[13]: Frame Flush■ TDES0[12]: Payload Checksum Error■ TDES0[11]: Loss of Carrier■ TDES0[10]: No Carrier■ TDES0[9]: Late Collision■ TDES0[8]: Excessive Collision■ TDES0[2]: Excessive Deferral■ TDES0[1]: Underflow error
14	JT: Jabber Timeout When set, this bit indicates that the MAC transmitter has experienced a jabber timeout. This bit can only be set when the Jabber Disabled (JD) bit of the EMACCFG register is clear.
13	FF: Frame Flushed When set, this bit indicates that the DMA flushed the frame because of a software flush command given by the CPU.
12	IPE: IP Payload Error When set, this bit indicates that MAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch.
11	LC: Loss of Carrier When set, this bit indicates that Loss of Carrier occurred during frame transmission. This is valid only for the frames transmitted without collision and when the MAC operates in half-duplex mode.
10	NC: No Carrier When set, this bit indicates that the carrier sense signal from the PHY was not asserted during transmission.
9	LC: Late Collision When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times including Preamble in MII Mode). Not valid if Underflow Error (bit 1) is set.
8	Excessive Collision When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the Disable Retry (DR) bit in EMACCFG register is set, this bit is set after the first collision and the transmission of the frame is aborted.
7	VF: VLAN Frame When set, this bit indicates that the transmitted frame was a VLAN-type frame.
6:3	CC: Collision Count This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collision bit (TDES0[8]) is set.

Table 24-16. Enhanced Transmit Descriptor 0 (TDES0) (continued)

Bit	Description
2	ED: Excessive Deferral When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times when Jumbo Frame is enabled). This bit is dependent on the Deferral Check (DC) bit being enabled in the EMACCFG register.
1	UF: Underflow Error When set, this bit indicates that the MAC aborted the frame because the data arrived late from system memory. Underflow Error indicates that the DMA encountered an empty Transmit Buffer while transmitting the frame. The transmission process enters the suspended state and sets both Transmit Underflow (UNF) and Transmit Interrupt (TI) bit in the EMACDMARIS register.
0	DB: Deferred Bit This bit indicates the deferral mechanism is active and that the transmit state machine sends a JAM pattern to defer reception when it senses a carrier before a normal transmission is scheduled.

Table 24-17. Enhanced Transmit Descriptor 1 (TDES1)

Bit	Description
31:29	SAIC: SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet frame with the value given in the MAC Address 0 register. If the Source Address field is modified in a frame, the MAC automatically recalculates and replaces the CRC bytes. The Bit 31 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[30:29]: <ul style="list-style-type: none"> ■ 0x0= Do not include the source address. ■ 0x1= Insert the source address. For reliable transmission, the application must provide frames without source addresses. ■ 0x2= Replace the source address. For reliable transmission, the application must provide frames with source addresses. ■ 0x3= Reserved These bits are valid when the First Segment control bit (TDES0[28]) is set.
28:16	TBS2: Transmit Buffer 2 Size This field indicates the second data buffer size in bytes. This field is not valid if TDES0[20] is set.
15:13	Reserved
12:0	TBS1: Transmit Buffer 1 Size These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]).

Table 24-18. Enhanced Transmit Descriptor 2 (TDES2)

Bit	Description
31:0	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. Note that the buffers are stored in SRAM.

Table 24-19. Enhanced Transmit Descriptor 3 (TDES3)

Bit	Description
31:0	<p>Buffer 2 Address Pointer (Next Descriptor Address)</p> <p>Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES0[20]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES0[20] is set.</p> <p>Note that the buffers are stored in SRAM.</p>

Table 24-20. Enhanced Transmit Descriptor 6 (TDES6)

Bit	Description
31:0	<p>TTSL: Transmit Frame Timestamp Low</p> <p>This field is updated by DMA with the least significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment bit (LS), TDES0[29], in the descriptor is set and Timestamp status (TTSS) bit, TDES0[17], is set.</p>

Table 24-21. Enhanced Transmit Descriptor 7 (TDES7)

Bit	Description
31:0	<p>TTSH: Transmit Frame Timestamp High</p> <p>This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding receive frame. This field has the timestamp only if the Last Segment bit (LS), TDES0[29], in the descriptor is set and Timestamp status (TTSS) bit , TDES0[17], is set.</p>

Enhanced Receive Descriptor

Figure 24-10 on page 1617 shows the enhanced receive descriptor. This descriptor is used when Advanced Timestamp or the Checksum Offload Engine is enabled.

Note: When Advanced Timestamp feature is enabled, software should set the ATDS bit of the **Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)** register, offset 0xC00, so that the DMA operates with extended descriptor size. When this bit is clear, the RDES4-RDES7 descriptor space is not valid.

Figure 24-10. Enhanced Receive Descriptor Structure

The following tables define the Enhanced Receive Descriptors.

Table 24-22. Enhanced Receive Descriptor 0 (RDES0)

Bit	Description
31	OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	AFM: Destination Address Filter Fail When set, this bit indicates a frame failed in the DA filter in the MAC.
29:16	FL: Frame Length These bits indicate the byte length of the received frame that was transferred to the system memory. This field is valid when the Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or the Overflow Error bit (RDES0[11]) is clear. When the Last Descriptor bit is not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. The inclusion of CRC length in the frame length depends on the settings of CRC configuration bits, ACS and CST in the EMACCFG register.

Table 24-22. Enhanced Receive Descriptor 0 (RDES0) (continued)

Bit	Description
15	<p>ES: Error Summary Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> ■ RDES0[14]: Descriptor Error ■ RDES0[11]: Overflow Error ■ RDES0[7]: Giant Frame ■ RDES0[6]: Late Collision ■ RDES0[4]: Watchdog Timeout ■ RDES0[3]: Receive Error ■ RDES0[1]: CRC Error ■ RDES[4:3]: IP Header or Payload Error <p>This field is valid only when the Last Descriptor (RDES0[8]) is set.</p>
14	<p>DE: Descriptor Error When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.</p>
13	<p>SAF: Source Address Filter Fail When set, this bit indicates that the SA field of frame failed the SA Filter in the MAC.</p>
12	<p>LE: Length Error When set, this bit indicates that the actual length of the frame received and the Length/ Type field do not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset. Length error status is not valid when CRC error is present.</p>
11	<p>OE: Overflow Error When set, this bit indicates that the received frame is damaged because of buffer overflow in RX FIFO.</p> <p>Note: This bit is set only when the DMA transfers a partial frame to the application. This happens only when the RX FIFO is operating in the threshold mode. In the store-and-forward mode, all partial frames are dropped completely in RX FIFO.</p>
10	<p>VLAN: VLAN Tag When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the MAC. The VLAN tagging depends on checking VLAN fields of the received frame configured in the Ethernet MAC VLAN Tag (EMACVLANTG) register, offset 0x01C</p>
9	<p>FS: First Descriptor When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.</p>
8	<p>LS: Last Descriptor When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame.</p>
7	<p>Timestamp Available or Giant Frame When Advanced Timestamp feature is enabled, this bit indicates that a snapshot of the Timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set. Otherwise, this bit, when set, indicates the Giant Frame Status. Giant frames are larger than 1,518-byte (or 1,522-byte for VLAN or 2,000-byte when Bit 27 of MAC Configuration register is set) normal frames and larger than 9,018-byte (9,022-byte for VLAN) frame when Jumbo Frame processing is enabled.</p>
6	<p>LC: Late Collision When set, this bit indicates that a late collision has occurred while receiving the frame in half-duplex mode.</p>

Table 24-22. Enhanced Receive Descriptor 0 (RDES0) (continued)

Bit	Description
5	FT: Frame Type When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 1,536). When this bit is reset, it indicates that the received frame is an IEEE 802.3 frame. This bit is not valid for Runt frames less than 14 bytes.
4	RWT: Receive Watchdog Timeout When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.
3	RE: Receive Error When set, this bit indicates that an error occurred during frame reception.
2	DE: Dribble Bit Error When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode.
1	CE: CRC Error When set this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor bit (RDES0[8]) is set.
0	Extended Status Available/RX MAC Address This bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This is valid only when the Last Descriptor bit (RDES0[8]) is set. This bit is invalid when Bit 30 is set.

Table 24-23. Enhanced Receive Descriptor 1 (RDES1)

Bit	Description
31	Disable Interrupt on Completion When set this bit prevents the setting of the bit Receive Interrupt (RI) bit in the EMACDMARIS register and prevents the receive interrupt from being asserted.
30:29	Reserved
28:16	RBS2: Receive Buffer 2 Size These bits indicate the second data buffer size. The buffer size must be a multiple of 4, even if the value of RDES3 (buffer2 address pointer) is not aligned to the bus width. If the buffer size is not an appropriate multiple of 4, the resulting behavior is undefined. This field is not valid if RCH bit (RDES1[14]) is set.
15	RER: Receive End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a Descriptor Ring.
14	RCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a don't care value. RDES1[15] takes precedence over RDES1[14].
13	Reserved
12:0	RBS1: Receive Buffer 1 Size Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4 even if the value of RDES2 (buffer 1 address pointer) is not aligned. When the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor depending on the value of RCH (Bit 14).

Table 24-24. Enhanced Receive Descriptor 2 (RDES2)

Bit	Description
31:0	<p>Buffer 1 Address Pointer</p> <p>These bits indicate the physical address of Buffer 1. The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. The DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored.</p> <p>Note that buffers should be word-aligned.</p>

Table 24-25. Enhanced Receive Descriptor 3 (RDES3)

Bit	Description
31:0	<p>Buffer 2 Address Pointer (Next Descriptor Address)</p> <p>These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[14]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[14] is set, the buffer (Next Descriptor) address pointer must be bus word-aligned (RDES3[1:0] = 0). However, when RDES1[14] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3 [1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored.</p>

The availability of the extended status is indicated by Bit 0 of RDES0. The following descriptors are available only when the Advanced Timestamp or IP Checksum Full Offload feature is enabled.

Table 24-26. Enhanced Received Descriptor 4 (RDES4)

Bit	Description
31:15	Reserved
14	<p>Timestamp Dropped</p> <p>When set, this bit indicates that the timestamp was captured for this frame but got dropped in the RX FIFO because of overflow.</p>
13	<p>PTP Version</p> <p>When set, this bit indicates that the received PTP message uses the IEEE 1588 version 2 format. When reset, it uses the version 1 format.</p>
12	<p>PTP Frame Type</p> <p>When set, this bit indicates that the PTP message is sent directly over Ethernet. When this bit is clear and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information about IPv4 or IPv6 can be obtained from Bits 6 and 7.</p>

Table 24-26. Enhanced Received Descriptor 4 (RDES4) (continued)

Bit	Description
11:8	<p>MessageType</p> <p>These bits are encoded to give the type of the message received:</p> <ul style="list-style-type: none"> ■ 0x0= No PTP message received ■ 0x1= SYNC (all clock types) ■ 0x2= Follow_Up (all clock types) ■ 0x3= Delay_Req (all clock types) ■ 0x4= Delay_Resp (all clock types) ■ 0x5= Pdelay_Req (in peer-to-peer transparent clock) ■ 0x6= Pdelay_Resp (in peer-to-peer transparent clock) ■ 0x7= Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) ■ 0x8= Announce ■ 0x9= Management ■ 0xA= Signaling ■ 0xB to 0xE= Reserved ■ 0xF= PTP packet with Reserved message type
7	<p>IPv6 Packet Received</p> <p>When set, this bit indicates that the received packet is an IPv6 packet. This bit is updated only when the IPC bit of the EMACCFG register is set.</p>
6	<p>IPv4 Packet Received</p> <p>When set, this bit indicates that the received packet is an IPv4 packet. This bit is updated only when the IPC bit of the EMACCFG register is set.</p>
5	<p>IP Checksum Bypassed</p> <p>When set, this bit indicates that the checksum offload engine is bypassed.</p>
4	<p>IP Payload Error</p> <p>When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the core calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. This bit is valid when either Bit 7 or Bit 6 is set.</p>
3	<p>IP Header Error</p> <p>When set, this bit indicates that either the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes, or the IP datagram version is not consistent with the Ethernet Type value. This bit is valid when either Bit 7 or Bit 6 is set.</p>

Table 24-26. Enhanced Received Descriptor 4 (RDES4) (continued)

Bit	Description
2:0	<p>IP Payload Type</p> <p>These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE). The COE sets this field to 0x0 if it does not process the IP datagram's payload due to an IP header error or fragmented IP packet.</p> <ul style="list-style-type: none"> ■ 0x0= Unknown or did not process IP payload ■ 0x1= UDP ■ 0x2= TCP ■ 0x3= ICMP ■ 0x4 to 0x7= Reserved <p>This bit is valid when either Bit 7 or Bit 6 is set.</p>

Table 24-27. Enhanced Receive Descriptor 6 (RDES6)

Bit	Description
31:0	<p>RTSL: Receive Frame Timestamp Low</p> <p>This field is updated by the DMA with the least significant 32 bits of the timestamp captured for the corresponding receive frame. This field is updated by the DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).</p>

Table 24-28. Enhanced Receive Descriptor 7 (RDES7)

Bit	Description
31:0	<p>RTSH: Receive Frame Timestamp High</p> <p>This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]).</p>

24.3.5 TX/RX Controller

The TX/RX Controller consists of a FIFO memory which buffers and regulates the frames between the system memory and the MAC. It also controls the data transferred between clock domains. Both the transmit and receive data paths are 32-bits wide. The TX FIFO and RX FIFO are each 2 KB in depth.

At reset, the TX/RX Controller is configured and ready to manage data flow to and from the DMA to the MAC. Note that the DMA and MAC must be initialized by the application out of reset.

24.3.5.1 Transmit (TX) Control Path

The DMA controller is used for all Ethernet transmissions. The Ethernet frames are read from memory and transferred to the TX FIFO by the DMA. When the MAC is available, the frame is transferred from the FIFO. When the end-of-frame (EOF) is transferred, the MAC notifies the DMA the status of the transmission.

The TX FIFO has a depth of 2 KB. The FIFO fill level has the capability of triggering the DMA to initiate a burst transfer. The DMA also transfers start-of-frame (SOF), end-of-frame (EOF), CRC and pad-insertion information to the TX/RX Controller so that this information can be passed to the MAC when it is ready for transmission from the TX FIFO.

Data can be transmitted to the MAC in threshold mode or store-and-forward mode. If the **TTC** field is configured in the **Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)** register at offset 0xC18 and the **TSF** bit in the same register is 0x0, then the TX Controller is operating in threshold mode. In this mode, the data is transferred to the MAC when the number of bytes in the FIFO crossed the value configured in the **TTC** bit field or when the end-of-frame is written before the threshold is crossed. In store-and forward mode, the **TTC** bit field is configured and the **TSF** bit is set. Data is transferred to the MAC only when one or more of the following conditions are true:

- A complete frame is stored in the FIFO
- The TX FIFO does not have space to accommodate the requested burst length

With these conditions, the TX Controller continues store-and-forward mode even if the Ethernet frame length is bigger than the TX FIFO size.

The TX FIFO can be flushed of all contents by setting the **FTF** bit in the **EMACDMAOPMODE** register. This bit is self-clearing and initializes the FIFO pointers to the default state. If the **FTF** bit is set during a frame transfer from the TX Controller to the MAC, then the TX Controller stops further transfer. Early termination of the transfer causes a underflow event and this status is communicated to the DMA.

Transmit Operation

During a transmit, single-packet or double-packets can reside in the buffer. The following describes the details of each:

- Single-packet transmit: During single packet transmission, the DMA controller fetches data from the CPU memory and forwards it to the TX FIFO and continues to receive data until the end-of-frame is transferred. The data is transmitted from the TX FIFO to the MAC by the TX/RX Controller when the threshold level is crossed or a full packet of data is received into the TX FIFO. When the TX/RX Controller receives acknowledgment from the MAC that it has received the EOF, it notifies the DMA so another transmit can begin.
- Two-packet transmit: Because the DMA must update the descriptor status before releasing it to the CPU, there can be at most two frames inside a transmit FIFO. The second frame is fetched by the DMA and put into the TX FIFO only if the **OSF** bit is set in the **EMACDMAOPMODE** register at offset 0xC18. If this bit is not set, the next frame is fetched from memory only after the MAC has completely processed the frame and the DMA has released the descriptors.

If the **OSF** bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. The TX/RX Controller receives the second frame into the FIFO while transmitting the first frame. As soon as the first frame has been transferred and the status is received from the MAC, the TX/RX Controller sends the acknowledgement to the DMA. If the DMA has already completed sending the second packet to the TX/RX Controller, it must wait for the status of the first packet before proceeding to the next frame.

Collision and Retransmission

If a collision occurs at the MAC application interface while the TX/RX Controller is transferring data to the MAC, the transmission is aborted and the MAC indicates a retry attempt by giving a collision status before the EOF is transferred to the TX/RX Controller from the DMA. This enables the TX/RX Controller to retry transmission of the frame data from the FIFO.

After more than 96 bytes are transferred to the MAC, the FIFO controller clears space in the FIFO and makes it available to the DMA to transfer more data. Retransmission is not possible after this threshold is crossed or when the MAC indicates a late collision event.

When a frame transmission is aborted because of underflow and a collision event follows, which initiates a retry, then the retry has higher priority than the abort.

TX FIFO Flush Operation

The TX FIFO can be flushed by setting the FTF bit in the **EMACDMAOPMODE** register. The flush operation is immediate and the TX/RX Controller clears the TX FIFO and the corresponding pointers to the initial state even if it is in the middle of transferring a frame to the MAC. The data which is already accepted by the MAC transmitter is not flushed. This data is scheduled for transmission and results in an underflow event because the TX FIFO did not complete the transfer or the rest of the frame. As in all underflow conditions, a runt frame is transmitted and observed on the line. The status of such a frame is marked with both underflow and frame flush events in the Transmit Descriptor 0 (TDES0) word.

The TX/RX Controller also stops accepting any data from the DMA during the flush operation. It generates and transfers Transmit Status Words to the application for the frames that are flushed inside the FIFO, including partial frames. Frames that are completely flushed in the TX/RX Controller are identified by setting the Flush Status (FF) bit in the Transmit Descriptor 0 (TDES0) word. The TX/RX Controller completes the flush operation when the DMA accepts all of the status words for the frames that were flushed and then clears the TX FIFO Flush control (FTF) bit in the **EMACDMAOPMODE** register. At this point, the TX/RX Controller starts accepting new frames from the DMA.

Transmit Status Word

At the end of the transfer of the Ethernet frame to the MAC and after the MAC completes the transmission of the frame, the TX/RX delivers a transmit status word (TDES0) to the application. If IEEE timestamping is enabled, the TX/RX Controller returns the specific frame's 64-bit timestamp, along with the transmit status word. The fields for the Transmit Descriptors are described in "Descriptors" on page 1603.

24.3.5.2 Receive (RX) Control Path

TX/RX Controller receives frames from the MAC and pushes them into the RX FIFO. When the fill level of the RX FIFO crosses the programmed RX Threshold, the DMA is notified.

Receive Operation

During a receive operation the TX/RX Controller is a slave to the MAC. The steps of the receive operation are as follows:

1. The MAC receives a frame. This data, along with SOF, EOF and byte enable information is sent to the TX/RX Controller. The TX/RX Controller accepts the data and pushes it into the RX FIFO. After the EOF is transferred, the MAC drives the status word, which is also pushed in to the RX FIFO.
2. When timestamp is enabled by setting the TSEN bit in the **Ethernet MAC Timestamp Control (EMACTIMSTCTRL)** register, at offset 0x700, and the 64-bit timestamp is present with the receive status, it is appended to the frame and received by the MAC and pushed into the TX FIFO before the corresponding receive status word is written. Thus, two additional locations per frame are taken for storing timestamp in the RX FIFO.

3. Data can be sent to the TX/RX Controller in cut-through mode or store-and-forward mode. When the RTC bit field of the **EMACDMAOPMODE** register is set to 0x0 and cut-through mode is enabled (RSF=0), the TX/RX Controller indicates availability to transfer to the DMA when 64 bytes are in the RX FIFO or a full packet of data has been received into the RX FIFO. When the DMA initiates transfers to system memory, the TX/RX Controller continues to transfer data from the RX FIFO until a complete packet has been transferred. When EOF has occurred, the TX/RX Controller sends the status word to the DMA.

Note: The timestamp transfer takes two clock cycles and the lower 32-bits of the timestamp are sent first when timestamping is enabled.

When the RSF bit is set in the **EMACDMAOPMODE** register, RX FIFO store-and-forward mode is enabled and a frame is read by the DMA only after it is completely written into the RX FIFO. In this mode, only valid frames are read and forwarded to the application. In cut-through mode, some error frames are not dropped because the error status is received at the end of the frame and by that time the start of that frame has already been read out of the RX FIFO.

The TX/RX Controller is capable of storing any number of frames in the RX FIFO as long as it is not full.

Error Handling

If the RX FIFO is full before it receives the EOF data from the MAC, an overflow is declared, the entire frame (including the status word) is dropped and the **Ethernet MAC Missed Frame and Buffer Overflow Counter (EMACMFBOC)** register is incremented. These error actions occur even if the FEF bit is set in the **EMACDMAOPMODE** register. If the start address of such a frame has already been transferred to the TX/RX Controller, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with its status word. The descriptor status indicates a partial frame because of overflow. In such frames, the Frame Length (FL) field in the receive descriptor is invalid. If the RX FIFO is configured to operate in the store-and-forward mode and if the length of the received frame is more than the FIFO size, overflow occurs and all such frames are dropped. During error handling, the DMA flushes the error frame currently being read.

The Receive control logic can filter error and undersized frames if enabled through configuring the FEF or FUF bit of the **EMACDMAOPMODE** register. Filtering must be set before the start address of the frame has been transferred to the TX/RX controller for it to take effect.

Receive Word Status

At the end of an Ethernet frame transfer to the system memory, the TX/RX Controller sends a receive status word, RDES0, to the application. Until the end of the frame transfer, the TX/RX Controller stores the status and frame length in an asynchronous status FIFO whose depth is determined by the size of the RX FIFO (2K) and the minimum size of the frame. If the frame size is 64, then the asynchronous FIFO depth is $2048/64 = 32$ bytes in length. Note that when the status of a partial frame (because of overflow) is sent to the application, the Frame Length field of RDES0 is not valid and is set to zero.

Note: When the timestamp feature is enabled, the receive status field is greater than 32-bits. An extended status bit-field [63:32] provides information about the received Ethernet payload when it is carrying PTP packets or TCP/UDP/ICMP over IP packets. Since the data bus is 32 bits, the status is transferred over two clock cycles.

24.3.5.3 MAC Flow Control

Flow control mechanisms can be enabled for both the TX and RX FIFO datapath, depending on the configurations in the **Ethernet MAC Flow Control (EMACFLOWCTL)** register at offset 0x018 and the DUPM bit configuration in the **Ethernet MAC Configuration (EMACCFG)** register at offset 0x000.

Table 24-29. TX MAC Flow Control

TFE bit in EMACFLOWCTL	DUPM bit in EMACCFG	Description
0	X	The MAC transmitter does not perform the flow control or backpressure operation.
1	0	The MAC transmitter performs backpressure when the FCBBPA bit in the Ethernet MAC Flow Control (EMACFLOWCTL) register is set.
1	1	The MAC transmitter sends a pause frame when the FCBBPA bit in the Ethernet MAC Flow Control (EMACFLOWCTL) register is set.

Table 24-30. RX MAC Flow Control

TFE bit in EMACFLOWCTL	DUPM bit in EMACCFG	Description
0	X	The MAC receiver does not detect the received Pause frames.
1	0	The MAC receiver does not detect the received Pause frames but recognizes such frames as Control frames.
1	1	The MAC receiver detects or processes the Pause frames and responds to such frames by stopping the MAC transmitter.

24.3.6 MAC Operation

The MAC module enables the CPU to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008 standard. The MAC supports the interface to the PHY and is comprised of a receive and transmit module whose features are described in the following sections.

24.3.6.1 MAC Transmit Module

MAC transmission is initiated when the TX/RX Controller transmits data with the start of frame (SOF) signal asserted. When the SOF signal is detected, the MAC accepts the data and begins transmitting to the PHY. The time required to transmit the frame data after the application initiates transmission varies, depending on delay factors like inter-frame gap (IFG) delay, time to transmit preamble or start of frame data (SFD), and any back-off delays for half-duplex mode. Until then, the MAC does not accept data received from the TX/RX Controller.

After the end-of-frame (EOF) is transferred to the MAC, the MAC completes the normal transmission and gives the status of transmission to the TX/RX Controller. If a normal collision (in half-duplex mode) occurs during transmission, the MAC conveys the transmit status to the TX/RX Controller. It then accepts and drops all further data until the next SOF is received. The TX/RX Controller should retransmit the same frame from SOF on observing a retry request (in the transmit status word) from the MAC. The MAC issues an underflow status if the TX/RX Controller is not able to provide the data continuously during the transmission. During the normal transfer of a frame from the TX/RX Controller, if the MAC receives an SOF without getting an EOF for the previous frame, it ignores the SOF and considers the new frame as a continuation of the previous frame.

If the number of bytes received from memory is less than 60 bytes, zeros are automatically appended to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE802.3.

The transmit engine controls the operation of Ethernet frame transmission. Some of the functions of the transmit module include:

- Output of (32-bit) Transmit Status (TDES0) to the application at the end of normal transmission or collision
- Generating preamble and Start of Frame Data (SFD)
- Generating jam pattern in half-duplex mode
- Supporting Jabber time-out
- Supporting flow control
- Generating timestamp information for transmission
- Scheduling frame transmission to satisfy inter-frame gap (IFG) and back-off delays
- Generating CRC and FCS field for Ethernet Frame
- Generating pause frames as necessary in full duplex mode

When a new frame transmission is requested, the MAC transmit module sends out a preamble and SFD, followed by the data in the TX FIFO. The preamble is defined as 7 bytes of 0xAA and the SFD is defined as 1 byte of 0xAB pattern.

The collision window is defined as 1 slot time (512-bit times). If a collision occurs any time from the beginning of the frame to the end of the CRC field, the MAC transmit module sends a 32-bit jam pattern of 0x5555.5555 to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the MAC transmit module completes the transmission of the preamble and SFD, and then sends the jam pattern. If the collision occurs after the collision window and before the end of the FCS field, the MAC transmit module sends a 32-bit jam pattern and sets the late collision bit in the transmit frame status. The jam pattern generation is applicable only to half-duplex mode.

A jabber timer is enabled by default at reset in the MAC module. If the **JD** bit in the **EMACCFG** register at offset 0x000 is clear and the MAC module has transferred more than 2K bytes, the jabber timer causes the MAC module to stop transmission of Ethernet frames. The timeout is changed to 10 KB when the Jumbo Frame Enable (**JFEN**) bit is enabled in the **EMACCFG** register.

The MAC transmit module uses a deferral mechanism for flow control (back pressure) in half-duplex mode. When the application requests to stop receiving frames, the transmit module sends a jam pattern of 32 bytes whenever it senses the reception of a frame, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a frame to be transmitted, the frame is scheduled and transmitted even when backpressure is activated. If the backpressure is activated for a long time (more than 16 consecutive collision events occur) then the remote stations abort their transmissions because of excessive collisions.

If IEEE 1588 timestamping is enabled for the transmit frame, the MAC transmit module takes a snapshot of the system time when the start-of-frame data is output on the bus.

24.3.6.2 MAC Transmit Module CRC Generator

The Transmit CRC Generator is used to generate the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1.$$

The calculated CRC is valid on the next clock after the data is received.

24.3.6.3 MAC Receive Module

A receive operation is initiated when the MAC detects start-of-frame data (SFD). The MAC strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field is used to verify the CRC for the frame. The received frame is stored in a buffer until the address filtering is performed. The frame is dropped in the MAC if it fails the address filter.

Some of the functions of the MAC receive module are as follows:

- Stripping the preamble, SFD and carrier extension of the Ethernet frame
- Providing IEEE 1588 timestamping whenever an SFD is detected
- Converting receive nibble data into bytes in MII mode
- Decoding Length/Type field of the Ethernet frame
- Auto-CRC/pad stripping if enabled in the **EMACCFG** register
- Frame data and status buffering for received frames
- Data path conversion of 8-bit data to 32-bit data
- Frame filtering
- Attaching calculated IP checksum input to frame
- Detecting receiving pause frames and pausing the frame transmission for the delay specified withing the received pause frame
- Receive IP Checksum Verification
- Performing destination and source address checking functions on all received frames and reporting the address filtering status to the receive frame controller module.

24.3.6.4 MAC Receive Module CRC Generator

The receive CRC Generator is used to generate the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The calculated CRC is valid on the next clock after the data is received.

24.3.6.5 MAC Receive Frame Controller

If the **RA** bit is set in the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)** register, offset 0x004, the MAC Receive Frame Controller initiates the data transfer to the RX FIFO as soon as four bytes of Ethernet data are received. At the end of the data transfer, the received frame status that includes the frame filter bits (SA or DA filter fail) and status are also sent. These bits indicate to the application whether the received frame has passed the filter controls. This module does not drop any frame on its own in this mode.

If the **RA** bit is clear, the MAC Receive Frame Controller performs frame filtering based on the destination/source address (the application still needs to perform another level of filtering if it decides

not to receive any bad frames like runt, CRC error frames, etc.) After receiving the destination or source address bytes, the MAC Receive Frame Controller checks the filter-fail sign for an address match. On detecting a filter-fail, the frame is dropped and not transferred to the application.

Note: When the PMT module is configured for power-down mode, all received frames are dropped and not forwarded to the application.

24.3.7 IEEE 1588 and Advanced Timestamp Function

The MAC module supports the IEEE 1588-2002 Timestamp Precision Time Protocol (PTP) and the IEEE 1588 Advanced Timestamp features. PTP enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by a local area network supporting multicast messaging. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The PTP is transported over UDP/IP. The system or network is classified into master and slave nodes for distributing the timing and clock information. Figure 24-11 on page 1629 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 24-11. Networked Time Synchronization

As shown in Figure 24-11 on page 1629, the PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t1. This time is captured at the MII interface.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_Up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master, noting the exact time, t3, at which this frame leaves the MAC.
5. The master receives the message, capturing the exact time, t4, at which it enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet MAC. This timing information is captured and returned to the software for the proper implementation of PTP with high accuracy.

24.3.7.1 System Time Module

The System Time module maintains a 64-bit time and is updated using the MOSC clock source as the PTP clock reference. This time is the source for taking snapshots (timestamps) of the Ethernet frames being transmitted or received. Two methods of updating the system time counter are implemented. The counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the **MAC System Time - Seconds Update (EMACTIMSECU)** register along with the **MAC System Time - Nanoseconds Update (EMACTIMNANOU)** register. For initialization the system time counter is written with the value in these registers, while for system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the slave clock's frequency drift with respect to the master clock is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the **EMACTIMADD** register, as shown in Figure 24-12 on page 1631. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high precision frequency multiplier or divider.

Figure 24-12. System Time Update Using Fine Correction Method

Note: If the Ethernet Controller is configured to use the MII/RMII interface to an external PHY, then the MOSC clock that feeds the PTP reference clock to the System Time Module has a minimum frequency requirement of 5 MHz and a maximum frequency of 25 MHz. For course correction methods, the value of MOSC can be anywhere within this range, but for the fine correction method, a 25 MHz value MOSC crystal should be used for the best accuracy. If the Ethernet Controller is configured to use the MII interface connected to the integrated PHY, then the MOSC clock that feeds the PTP reference clock to the System Time Module must be 25 MHz because it also clocks the integrated PHY module.

Initially, the Ethernet's slave clock (from the MOSC) is adjusted with a compensation value (as described in the previous paragraph) which is written to the Timestamp Addend Register (TSAR) field in the **EMACTIMADD** register. This value is calculated as: $\text{FreqCompensationValue}_0 = \text{TSAR} = 2^{32} / \text{FreqDivisionRatio}$.

The System Time Module requires a 20-MHz PTP reference clock frequency to achieve 50-ns accuracy in the fine correction method. An addend must be written to the **Ethernet MAC Time Stamp Addend (EMACTIMADD)** register, offset 0x718 to achieve timing synchronization. If the MOSC clock source is 25 MHz, the frequency division ratio (FreqDivisionRatio) of the two is calculated as $25 \text{ MHz} / 20 \text{ MHz} = 1.25$. Hence, the default addend value to be set in the register is $2^{32} / 1.25$ or 0xCCCC.CCD0. If the reference clock drifts lower, to 24 MHz for example, the ratio is $24 / 20$, or 1.2 and the value to set in the addend register is $2^{32} / 1.20$, or 0xDFF1.65D2. The software must

calculate the drift in frequency based on the Sync messages and update the **EMACTIMADD** register, at offset 0x718, accordingly.

If the master to slave delay is initially assumed to be the same for consecutive Sync messages, then the following steps can be used to calculate a new TSAR value. The following algorithm calculates the precise master to slave delay value to allow for re-synchronization with the master using the new value:

1. At time MasterSyncTime_n the master sends the slave clock a Sync message. The slave receives this message when its local clock is SlaveClockTime_n and computes MasterClockTime_n as:

$$\text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n$$

2. The master clock count, $\text{MasterClockCount}_n$, for the current Sync cycle is given by:

$$\text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1}$$

This assumes that the $\text{MasterToSlaveDelay}$ is the same for Sync cycles n and n-1.

3. The slave clock count for current Sync cycle, SlaveClockCount_n is given by:

$$\text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1}$$

4. The difference between the master and slave clock counts for the current Sync cycle, ClockDiffCount_n , is given by:

$$\text{ClockDiffCount}_n = \text{MasterClockCount}_n - \text{SlaveClockCount}_n$$

5. The frequency-scaling factor for the slave clock, FreqScaleFactor_n is given by:

$$\text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n$$

6. The frequency compensation value, $\text{FreqCompensationValue}$, to be written in the TSAR field of the **EMACTIMADD** register is:

$$\text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n * \text{FreqCompensationValue}_{n-1}$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.

24.3.7.2 Transmit Timestamping

The MAC captures a timestamp when the Start Frame Delimiter (SFD) of a frame is sent. The transmit frames are marked to indicate whether a timestamp should be captured for that frame and written to the extended transmit descriptors that support timestamping. The MAC returns the timestamp automatically to the corresponding transmit descriptor, thus connecting the timestamp with the specific PTP frame. The 64-bit timestamp information is written to the TDES2 and TDES3 fields.

Note: When the enhanced descriptor size is selected by setting the ATDS bit in the **EMACDMABUSMOD** register, a larger descriptor is used and the MAC writes the 64-bit timestamp information to TDES6 and TDES7, respectively.

24.3.7.3 Receive Timestamping

The MAC captures the timestamp of all received frames. The MAC does not process the received frames to identify the PTP frames in default timestamping mode (when Advanced Timestamp is disabled). The MAC gives the timestamp and the corresponding status to the TX/RX Controller along with the EOF data. The TX/RX Controller validates and indicates the availability of the timestamp so that the DMA can return the timestamp to the corresponding receive descriptor. The 64-bit timestamp information is written to the RDES2 and RDES3 fields. The timestamp is written only to the receive descriptor for which the Last Descriptor status field has been set to 1 (the EOF marker). When the timestamp is not available (for example, because of an RX FIFO overflow), an all '1s' pattern is written to the descriptors (RDES2 and RDES3), indicating that the timestamp is not correct. If timestamping is disabled, the DMA does not alter RDES2 or RDES3.

Note: When the enhanced descriptor size is selected by setting the ATDS bit in the **EMACDMABUSMOD** register, the 64-bit timestamp is written to RDES6 and RDES7, respectively. RDES0[7] indicates whether the timestamp is updated in RDES6 and RDES7.

24.3.7.4 Timestamp Error Margin

According to the IEEE 1588 specifications, a timestamp must be captured at the SFD of the transmitted and received frames at the MAC interface. Because the reference timing source, MOSC, is taken as different from MAC reference clocks, a small error margin is introduced, because of the transfer of information across asynchronous clock domains. In the transmit path, the captured and reported timestamp has a maximum error margin of 2 PTP (MOSC) clocks. It means that the captured timestamp has the reference timing source (MOSC) value that is given within 2 clocks after the SFD has been transmitted to the PHY. Similarly, in the receive path, the error margin is 3 MAC reference clocks, plus up to 2 PTP clocks. The error margin of the three MAC reference clocks can be ignored by assuming that this constant delay is present in the system (or link) before the SFD data reaches the interface of MAC.

Note: When the Ethernet Controller is configured to use the MII interface to an external PHY, the MII clock is provided by the external PHY through EN0RXCK and EN0TXCK. When the Ethernet Controller is connected to the integrated PHY, the reference clock must be 25 MHz because it is also the source to the PHY.

Note: When IEEE 1588 timestamping is enabled with internal timestamp, use a PTP clock frequency that is greater than 5 MHz. This is because the SSINC field in the **EMACSUBSECINC** register limits the PTP frequency that can be used to ~4 MHz.

24.3.7.5 IEEE 1588-2008 Advanced Timestamps

In addition to the basic timestamp features mentioned in IEEE 1588-2002 Timestamps, the Ethernet Controller supports the following advanced timestamp features defined in the IEEE 1588-2008 standard:

- Supports the IEEE 1588-2008 (version 2) timestamp format.
- Provides an option to take snapshot of all frames or only PTP type frames.
- Provides an option to take snapshot of only event messages.
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end, and peer-to-peer.
- Provides an option to select the node to be a master or slave clock.

- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.
- Provides an option to measure sub-second time in digital or binary format.

Peer-to-Peer Transparent Clock Message Support

The IEEE 1588-2008 version supports Peer-to-Peer PTP (Pdelay) message in addition to SYNC, Delay Request, Follow-up, and Delay Response messages. Figure 24-13 on page 1634 shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

Figure 24-13. Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

As shown in Figure 24-13 on page 1634, the propagation delay is calculated in the following way:

- Port-1 issues a Pdelay_Req message and generates a timestamp, t_1 , for the Pdelay_Req message.
- Port-2 receives the Pdelay_Req message and generates a timestamp, t_2 , for this message.
- Port-2 returns a Pdelay_Resp message and generates a timestamp, t_3 , for this message.

To minimize errors because of any frequency offset between the two ports, Port-2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. The Port-2 returns any one of the following:

- The difference between the timestamps t_2 and t_3 in the Pdelay_Resp message.
- The difference between the timestamps t_2 and t_3 in the Pdelay_Resp_Follow_Up message.

- The timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.
4. Port-1 generates a timestamp, t4, on receiving the Pdelay_Resp message.
 5. Port-1 uses all four timestamps to compute the mean link delay.

Advanced Timestamp Supported Clock Types

The Advance Timestamp Module supports an ordinary clock as defined by the IEEE 1588-2008 standard. The characteristics of this clock is as follows:

- Sending and receiving of PTP messages. The timestamp snapshot can be controlled through the **Ethernet MAC Timestamp Control (EMACTIMSTCTRL)** register, offset 0x700. Timestamp snapshots can be for Sync messages.
 - Maintaining the data sets such as timestamp values.
- For an ordinary clock, snapshots can be taken of either version 1 or version 2 PTP types but not both. Selecting between the two is controlled by the **PTPVER2** bit of the **EMACTIMSTCTRL** register.

PTP Processing and Control

There are fields in an Ethernet Payload that the Ethernet Controller can use to detect the PTP packet type and control the snapshot to be taken. These fields are different depending on whether the PTP frames are:

- PTP frames over IPv4
- PTP frames over IPv6
- PTP frames over Ethernet

The PTPIP4, PTPIP6 or PTPETH bits can be set depending on which PTP processing is required.

Reference Timing Source

The MAC supports the following reference timing source features defined in the IEEE 1588-2008 standard:

- 80-bit timestamp
- Fixed Pulse-Per-Second PPS0 Output
- Flexible Pulse-Per-Second PPS0 Output

80-Bit Timestamp

The MAC supports an 80-bit timestamp with a lengthened seconds integer portion which is 48-bits wide. The **Ethernet MAC System Time - Seconds (EMACTIMSEC)** register at offset 0x708 and the **Ethernet MAC System Time-Higher Word Seconds (EMACHWORDSEC)** register at offset 0x724 comprise the seconds count. The 32-bit **Ethernet MAC System Time - Nanoseconds (EMACTIMNANO)** register contains the fractional portion of the timestamp units of nanoseconds. The nanoseconds register supports the following two modes:

- Digital rollover mode: In digital rollover mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
- Binary rollover mode: In binary rollover mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

Digital or binary rollover mode can be selected by programming the DGTLBIN bit of the **EMACTIMSTCTRL** register. Note that the timestamp maintained in the MAC is still 64-bits wide, but that the overflow to the upper 16-bits seconds register happens once in 130 years.

Fixed Pulse-Per-Second Output

The Ethernet MAC module supports a pulse-per-second output feature such that the signal, ENOPPS, can indicate one second intervals. The frequency of the ENOPPS output can be changed by setting the PPSCTRL bit field of the **Ethernet MAC PPS Control (EMACPPSCTRL)** register, offset 0x72C.

Flexible Pulse-Per-Second Output

The Ethernet MAC also provides the ability to control the following features of the ENOPPS output:

- Start or stop time
- The start point of a single pulse and the start and stop points of the pulse train in terms of a 64-bit system time. The **EMACTIMESEC** and **EMACTIMNANO** registers are used to program the start and stop time.
- The stop time can be programmed in advance of starting.
- The signal width. The rising edge and the corresponding falling edge of the ENOPPS output can be programmed in terms of number of units of sub-second increment value programmed in the **Ethernet MAC Sub-Second Increment (EMACSUBSECINC)** register, offset 0x704.
- The signal interval. The time between the rising edges of ENOPPS signal, in terms of number of units of sub-second increment value can be programmed in the **Ethernet MAC PPS0 Interval (EMACPPS0INTVL)** register, offset 0x760 . You can program the interval between pulses from 1 to $2^{32}-1$ units of sub-second increment value.
- Cancellation of the programmed ENOPPS start or stop request.
- Error indication if the start or stop time being programmed has already passed.

The start time can be programmed in the **EMACTARGSEC** and **EMACTARGNANO** registers. The TRGTBUSY bit in the **EMACTARGNANO** register indicates when the value is synchronized to the PTP clock domain. When this bit is clear, a new start time can be programmed, even before the earlier start time has elapsed. The start or stop time should be programmed with advanced system time to ensure proper ENOPPS signal output. If the application programs a start or stop time that has already elapsed, then the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

For a flexible ENOPPS output, the **EMACPPS0INTVL** and **EMACPPS0WIDTH** registers can be configured. The **PPS0WIDTH** and **PPS0INT** fields are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a ENOPPS pulse width of 80 ns and interval of 120 ns, with the PTP reference clock of 25MHz, you should

program the width and interval to values 1 and 2, respectively. Note that the PPS0WIDTH and PPS0INT value must be programmed as one less than the required interval. Before giving the command to trigger a pulse or pulse train on the EN0PPS output, the interval and width of the PPS signal output should be programmed or updated.

Advanced Timestamp Transmit Path Functions

The only aspect of the transmit path that changes with advanced timestamp is the descriptor, which extends to 32-bytes long.

When you enable the advanced timestamp feature, the structure of the descriptor changes. The advanced timestamp feature is supported only through the enhanced descriptors format. The descriptor is 32-bytes long (eight words) and the snapshot of the timestamp is written in descriptor TDES6 and TDES7.

Advanced Timestamp Receive Path Functions

When the advanced timestamp feature is enabled, the MAC processes the received frames to identify valid PTP frames. The snapshot of the time sent to the application can be configured to:

- Enable snapshot for all frames
- Enable snapshot for IEEE 1588 version 2 or version 1 timestamp.
- Enable snapshot for PTP frames transmitted directly over Ethernet or UDP-IP-Ethernet.
- Enable timestamp snapshot for the received frame for IPv4 or IPv6.
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP).
- Enable the node to be a master or slave and select the snapshot type. This controls the type of messages for which snapshots are taken.

The MAC provides the timestamp, along with EOF to the TX/RX Controller. The DMA returns the timestamp inside the corresponding receive descriptor.

24.3.8 Frame Filtering

The following types of filtering are available for receive frames:

- Source Address (SA) or Destination Address (DA) filtering
- VLAN Filtering

The frame filtering supports a sequence where the packet is not forwarded to VLAN filtering if it does not pass the SA or DA filtering first.

24.3.8.1 VLAN Filtering

The Ethernet MAC provides VLAN Tag Perfect Filtering and VLAN Tag Hash Filtering. In VLAN tag perfect filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode of the ETV bit in the **EMACVLANTG** register, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag perfect filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status and drops the VLAN frames that do not match. Inverse matching for VLAN frames can also be enabled by setting the VTIM bit of the **Ethernet MAC VLAN**

Tag (EMACVLANTG) register, offset 0x01C. In addition, matching of S-VLAN tagged frames along with the default C-VLAN tagged frames can be enabled by setting the **ESVL** bit of the **EMACVLANTG** register. The VLAN frame status bit (Bit 10 of RDES0) indicates the VLAN tag match status for the matched frames.

Note: The Source or Destination Address filter has precedence over the VLAN tag filters. A frame which fails the Source or Destination Address filter is dropped irrespective of the VLAN tag filter results.

The MAC provides VLAN tag hash filtering with a 16-bit Hash table. The MAC performs the VLAN hash matching based on the **VTHM** bit of the **EMACVLANTG** register. If the **VTHM** bit is set, the most significant four bits of VLAN tag's CRC-32 are used to index the content of the **Ethernet MAC VLAN Hash Table (EMACVLANHASH)** register, offset 0x588. A value of 1 in the **EMACVLANHASH** register, corresponding to the index, indicates that the VLAN tag of the frame matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged frame should be dropped. The MAC also supports the inverse matching of the VLAN frames. In the inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a frame is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch. Table 24-31 on page 1638 shows the different possibilities for VLAN matching and the final VLAN match status. When the **RA** bit of the **EMACFRAMEFLTR** register is set, all frames are received and the VLAN match status is indicated in Bit 10 of Receive Descriptor word 0 (RDES0). When the **RA** bit is not set and the **VTFF** bit in the **EMACFRAMEFLTR** register is set, the frame is dropped if the final VLAN match status is fail. In Table 24-31 on page 1638, value X means that this column can have any value. When the **VL** field is programmed to 0x0 in **EMACVLANTG** register, all VLAN-tagged frames are considered as perfect matched but the status of the VLAN hash match depends on the VLAN hash enable (**VTHM**) bit and VLAN inverse filter (**VTIM**) bit.

Table 24-31. VLAN Match Status

VLAN ID (VL field)	VLAN Perfect Filter Match Status (VPF)	VLAN HASH Enable bit (HPF bit in EMACFRAMEFLTR)	VLAN Hash Filter Match Status (VTHM)	VLAN Inverse Filter Bit (VTIM)	Final VLAN Match Status
VL = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VL !=0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

24.3.9 Source Address, VLAN, and CRC Insertion, Replacement or Deletion

The MAC supports the following functions for transmit frames:

- Source Address Insertion or replacement

- VLAN Insertion, Replacement or Deletion
- CRC Replacement

24.3.9.1 Source Address Insertion or Replacement

Software can use the SA insertion or replacement feature to instruct the MAC to do the following for transmit frames:

- Insert the content of the MAC Address Registers in the SA field.
- Replace the content of the SA field with the content of the MAC Address Registers.

The software can enable the SA insertion or replacement for all transmitted frames or selective frames:

- To enable SA insertion or replacement feature for all frames, program the SADDR field of the **Ethernet MAC Configuration (EMACCFG)** register.
- To enable SA insertion or replacement for selective frames, program the SA Insertion Control field (TDES1 Bits [31:29]) in the first transmit descriptor of the frame. When Bit 31 of TDES1 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 31 of TDES1 is reset, it indicates insertion or replacement by MAC Address 0 registers.

When SA insertion is enabled, the application should ensure that the frames that are sent to the MAC do not have the SA field. The MAC does not check the presence of SA field in the transmit frame and just inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application should ensure that the frames that are sent to the MAC have the SA field. The MAC just replaces the six bytes, following the Destination Address field in the transmit frame, with the content of the MAC Address Registers.

24.3.9.2 VLAN Insertion, Replacement or Deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for transmit frames:

- Insert or replace the VLAN Type field (C-VLAN or S-VLAN indicated by the CSVL bit of the **Ethernet MAC VLAN Tag Inclusion or Replacement (EMACVLNINCREP)**, MAC offset 0x584) and the VLAN Tag field in the transmit frame with the VLT field of the **EMACVLNINCREP** register.
- Delete the VLAN Type and VLAN Tag fields in the transmit frame.

The software can enable the VLAN insertion, replacement, or deletion feature for all transmitted frames or selective frames. To enable this function for all transmit frames, configure the VLT field in the **EMACVLNINCREP** register.

When VLAN replacement or deletion is enabled, the MAC checks the presence of the VLAN Type field (0x8100 or 0x88a8), after the Destination address (DA) and SA fields, in the transmit frame. The replace or delete operation does not occur if the VLAN Type field is not detected in the two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the transmit frame and just inserts the VLAN Type and VLAN Tag fields.

24.3.9.3 CRC Replacement

The software can use the CRC replacement feature to instruct the MAC to replace the FCS field in the transmit frame with the CRC computed by the MAC. This feature works on a per-frame basis. The CRC replacement control field in the Transmit Descriptor Word 0 (TDES0) can be programmed to enable this for a frame. This feature is valid only when the Disable CRC control (Bit 27 of TDES0) is enabled. If SA or VLAN insertion control is enabled, the MAC appends or replaces the FCS field with the computed CRC when Disable CRC Control is enabled or disabled, respectively.

Table 24-32. CRC Replacement Based on Bit 27 and Bit 24 of TDES0

Bit 27 (DC)	Bit 24 (CRCR)	Description
0	X	Append CRC When DC= 0, the MAC appends the computed CRC irrespective of the CRCR setting.
1	1	Replace CRC
1	0	No operation (user has appended CRC)

24.3.10 Checksum Offload Engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the MAC Checksum Offload Engine (COE) supports checksum calculation and insertion in the transmit path, and error detection in the receive path.

24.3.10.1 Transmit Checksum Offload Engine

The checksum for TCP, UDP, or ICMP is calculated over a complete frame, and then inserted into its corresponding header field. Because of this requirement this function is enabled only when the TX FIFO is configured for the store-and-forward mode (the TSF bit is set in the **EMACDMAOPMODE** register).

Note: The TX FIFO must be deep enough to store a complete frame before the frame is transferred to the MAC when the checksum offload is being used. If space is not available to accept the programmed burst length of data, the TX/RX Controller starts reading to avoid deadlock. When reading starts, the checksum offload fails and the consequently all succeeding frames may be corrupted because of improper recovery. Therefore, checksum insertion must only be enabled in frames that are less than $[2048 - ((PBL+3)*4)]$ bytes in size, where PBL is the Programmable Burst Length field in the **EMACDMABUSMOD** register.

24.3.10.2 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The checksum offload engine detects an IPv4 datagram when the Ethernet frame's Type field has the value 0x0800 and the IP datagram's Version field has the value 0x4. The input frame's checksum field is ignored during calculation and replaced with the calculated value. IPv6 headers do not have a checksum field. Therefore, the checksum offload does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 16 in TDES0). This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
 - The received Ethernet type is 0x0800, but the IP header's Version field is not equal to 0x4.
 - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
 - The total frame length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
 - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
 - The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

If the checksum offload engine detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

24.3.11 MAC Management Counters

The MAC Management Counters (MMC) module maintains a set of registers for gathering statistics on the received and transmitted frames. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (one for receive and one for transmit), and two 32-bit registers containing masks for the Interrupt register (one for receive and one for transmit). The MMC counters are free running and start counting when a corresponding frame is received or transmitted. The MMC counter registers provided are as follows:

- **Ethernet MAC Transmit Frame Count for Good and Bad Frames (EMACTXCNTGB)**
- **Ethernet MAC Transmit Frame Count for Frames Transmitted after Single Collision (EMACTXCNTSCOL)**
- **Ethernet MAC Transmit Frame Count for Frames Transmitted after Multiple Collisions (EMACTXCNTMCOL)**
- **Ethernet MAC Transmit Octet Count Good (EMACTXOCTCNTG)**
- **Ethernet MAC Receive Frame Count for Good and Bad Frames (EMACRXCNTGB)**
- **Ethernet MAC Receive Frame Count for CRC Error Frames (EMACRXCNTCRCERR)**
- **Ethernet MAC Receive Frame Count for Alignment Error Frames (EMACRXCNTALGNERR)**
- **Ethernet MAC Receive Frame Count for Good Unicast Frames (EMACRXCNTGUNI)**

24.3.12 Power Management Module

The power management (PMT) module supports the reception of network remote wake-up frames and AMD Magic Packet™ frames. The PMT module does not perform the clock gate function, but generates interrupts for remote wake-up frames and magic packets that the MAC receives.

When the application enables the power-down mode in the PMT module by setting the PWRDWN bit in the **Ethernet MAC PMT Control and Status Register (EMACPMTCTLSTAT)** register, MAC offset 0x02C, the MAC drops all received frames and does not forward any frame to the TX/RX Controller RxFIFO or the application. The MAC comes out of the power-down mode only when a magic packet or a remote wake-up frame is received and the corresponding detection is enabled.

24.3.12.1 Remote Wake-Up

The Remote Wake-Up register bank is made up of eight 32-bit registers. It is loaded by writing the **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register eight times. To load values in the **EMACRWUFF** register, the entire register must be written. The first write is assigned to register 0 of the bank, then register 1 and so on. The **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register is read the same way. The current pointer value of the bank is updated in the Remote Wake-Up FIFO Pointer (RWPTR) field of the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register.

Figure 24-14. Wake-Up Frame Filter Register Bank

Filter 0 Byte Mask							
Filter 1 Byte Mask							
Filter 2 Byte Mask							
Filter 3 Byte Mask							
RSVD	Filter 3 Command	RSVD	Filter 2 Command	RSVD	Filter 1 Command	RSVD	Filter 0 Command
Filter 3 Offset	Filter 2 Offset	Filter 1 Offset	Filter 0 Offset				
Filter 1 CRC - 16				Filter 0 CRC - 16			
Filter 3 CRC - 16				Filter 2 CRC - 16			

Filter n Byte Mask

The Filter n Byte Mask registers of the Remote Wake-Up register define the bytes of the frame that are examined by filter n (0, 1, 2, and 3) in order to determine whether or not a frame is a remote wake-up frame. The most significant bit (bit 31) of each mask must be zero. Bits [30:0] are the Byte Mask. If bit, j, of the Byte Mask is set, then the CRC block processes the Filter n Offset + j of the incoming frame; otherwise Filter n Offset + j is ignored.

Filter n Command

The 4-bit Filter n Command field controls the Filter n operation in the following way:

- Filter n Command Bit 3 specifies the address type of the pattern. When the bit is set, the pattern applies to only multicast frames; when the bit is reset, the pattern applies only to unicast frame.
- Filter n Command Bit 2 and Bit 1 are reserved.
- Filter n Command Bit 0 is the enable for Filter n. If bit 0 is not set, filter n is disabled.

Filter n Offset

The Filter n Offset register defines the offset (within the frame) from which the filter n examines the frames. This 8-bit pattern offset is the offset for the filter n first byte to be examined. The minimum

allowed offset is 12, which refers to the 13th byte of the frame. The offset value 0 refers to the first byte of the frame.

Filter n CRC-16

The Filter n CRC-16 register contains the CRC_16 value calculated from the pattern and the byte mask programmed to the wake-up filter register block.

24.3.12.2 Remote Wake-Up Frame Detection

When the MAC is in sleep mode and the remote wake-up frame enable bit, WUPFREN, is set in the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register, the normal operation is resumed after a remote wake-up frame is received. The application writes all eight wake-up filter registers, by performing eight sequential writes to the **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register. The Power Management (PMT) block supports four programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of Filter Command, and if Filter CRC-16 matches the CRC of the incoming pattern, then the MAC identifies the frame as wake-up frame. The Filter Offset determines the offset from which the frame is to be examined. The Filter Byte Mask determines which bytes of the frame must be examined. The 31st bit of Byte Mask must be set to zero. The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The remote wake-up frame is checked only for length error, FCS error, dribble bit error, MII error, and collision. In addition, the remote wake-up frame is checked to ensure that it is not a runt frame. Even if the remote wakeup frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. The remote wake-up frame detection is updated in the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register for every remote wake-up frame received. If the PMT interrupt is enabled in the **Ethernet MAC Interrupt Mask (EMACIM)** register, a PMT interrupt is asserted and the **EMACPMTCTLSTAT** register can be read to determine reception of a remote wake-up frame.

24.3.12.3 Magic Packet Detection

The magic packet frame is based on a method that uses Advanced Micro Device's magic packet technology to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network. The MAC checks only those magic packets that are addressed to the MAC or a broadcast address to determine whether these packets meet the wake-up requirements. The magic packets that pass the address filtering (unicast or broadcast) are checked to determine whether they meet the remote wake-up frame data format of 6 bytes of all ones followed by a MAC Address appearing 16 times. The application enables the magic packet wake-up by setting the magic packet enable bit, MGPKTEN, of the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register. The power management block constantly monitors each frame addressed to the node for a specific magic packet pattern. Each frame received is checked for a 0xFFFF.FFFF.FFFF pattern following the destination and source address field. The power management block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again scans the 0xFFFF.FFFF.FFFF pattern in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (0xFFFF.FFFF.FFFF). The device can also accept a multicast frame, as long as the 16 duplications of the MAC address are detected. If the MAC address of a node is 0x0011.2233.4455, then the MAC scans for the following data sequence:

```
Destination Address Source Address ..... FF FF FF FF FF FF  
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55  
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
```

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 ...CRC

The magic packet detection is updated in the **EMACPMTCTLSTAT** register for the received magic packet. If the PMT interrupt is enabled in the **Ethernet MAC Interrupt Mask (EMACIM)** register, a PMT interrupt is asserted and the **EMACPMTCTLSTAT** register can be read to determine whether a magic packet frame has been received.

24.3.12.4 Power Management Interrupts

The PMT interrupt signal can be asserted when a valid remote wake-up frame or magic packet is received. The PMT interrupt signal restores the application clock and TX clock to the MAC. When the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register is read, the PMT interrupt is cleared in the **EMACRIS** register at least after four clock cycles of RX clock. When software resets the PWRDWN bit in the **Ethernet MAC PMT Control and Status (EMACPMTCTLSTAT)** register, the MAC comes out of the power-down mode, but this event does not generate a PMT interrupt.

24.3.12.5 Power-Down/Wake-Up Sequence

The recommended power-down and wake-up sequence is as follows:

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. These transmissions can be detected when TI is set in the **Ethernet MAC DMA Interrupt Status (EMACDMARIS)** register.
2. Disable the MAC transmit and receive state machine by clearing the TE and RE bits in the **Ethernet MAC Configuration (EMACCFG)** register.
3. Wait until the RX DMA empties all the frames from the Rx FIFO to system memory by polling the RXF field of the **Ethernet MAC Status (EMACSTATUS)** register.
4. Enable a power management mode by setting the magic packet, global unicast or remote wake-up enable bit in the **EMACPMTCTLSTAT** register.
5. Enable the MAC receive state machine in the **EMACCFG** register and enter the Power-Down mode by setting the PWRDWN bit in the **EMACPMTCTLSTAT** register.
6. On receiving a valid remote wake-up frame, the PMT interrupt is set in the **EMACRIS** register and the Ethernet MAC exits the Power-Down mode.
7. Read the **EMACPMTCTLSTAT** register to clear the PMT interrupt, then enable the other modules in the system and resume normal operation.

24.3.13 Serial Management Interface

The Ethernet MAC has the ability to read or write to the PHY registers through the EN0MDIO and EN0MDC signals of the Serial Management Interface defined by the IEEE 802.3 standard. The internal EN0MDIO and EN0MDC signals connect to the integrated PHY as well as to the external EN0MDIO and EN0MDC pins. The EN0MDC signal is a 2.5 MHz clock that is sourced from System Clock (SYSCLK) and then divided down to the required frequency by programming the CR field in the **Ethernet MAC MII Address (EMACMIIADDR)** register. To access the integrated PHY, the PLA field in the **EMACMIIADDR** register must be 0x0. The available addresses for external PHYs are 0x01 to 1F.

24.3.14 Reduced Media Independent Interface (RMII)

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Ethernet MACs. According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces such as switches, the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port — a 62.5% decrease in pin count.

The RMII module has the following features:

- Supports both 10-Mbps and 100-Mbps operating rates
- Provides independent, two-bit wide transmit and receive paths

Each nibble is transmitted on the RMII two bits at a time. For a nibble {D3, D2, D1, D0}, the data is transferred as {D1, D0} followed by {D3, D2}.

24.3.15 Interrupt Configuration

Interrupts can be generated from the MAC as a result of various events in the MAC and sub-modules. MAC interrupts are enabled or disabled in the **Ethernet MAC Interrupt Mask (EMACIM)** register, MAC offset 0x03C. Each interrupt event can be masked by setting the corresponding mask bit in the **EMACIM** register.

The interrupt register bits in the **Ethernet MAC Raw Interrupt Status (EMACRIS)** register only indicate the sub-module from which the event is reported. The application must read the corresponding status registers to clear the interrupt.

24.4 EMAC Initialization and Configuration

The EMAC interface defaults to MII mode. To initialize the RMII interface:

1. The MAC module and registers are enabled and powered at reset. When reset has completed, the application should enable the clock to the Ethernet MAC by setting the R0 bit in the **Ethernet Controller Run Mode Clock Gating Control (RCGCEMAC)** register at System Control Module offset 0x69C.
2. Enable the external clock source input to the RMII interface signal EN0RREF_CLK by setting both the ECEXT and CLKEN bit in the **Ethernet Clock Configuration (EMACCC)** register at offset 0xFC8. The external clock source must be 50 MHz with a frequency tolerance of 50 PPM.
3. Select the RMII interface by programming the PINTFS bit field to 0x4 in the **Ethernet Peripheral Configuration (EMACPC)** register at offset 0xFC4.
4. Reset the Ethernet MAC to latch the new RMII configuration by setting the SWR bit in the **EMACDMABUSMOD** register. This bit resets the Ethernet MAC registers in addition to configuring the RMII interface. Software must poll the SWR bit to determine when the new configuration has been registered.

After this configuration is active, if the Ethernet MAC is reset by setting the R0 bit in the **Ethernet MAC Software Reset (SREMAC)** register in the System Control Module, then the interface is set back to its default MII configuration. In this case, the steps listed above must be repeated to return to an RMII interface.

The Initialization for the DMA for the Ethernet MAC is as follows:

1. Write to the Ethernet **MAC DMA Bus Mode (EMACDMABUSMOD)** register to set Host bus parameters.
2. Write to the Ethernet **MAC DMA Interrupt Mask Register (EMACDMAIM)** register to mask unnecessary interrupt causes.
3. Create the transmit and receive descriptor lists and then write to the **Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)** register and the **Ethernet MAC Transmit Descriptor List Address (EMACTXDLADDR)** register providing the DMA with the starting address of each list.
4. Write to the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)** register, the **Ethernet MAC Hash Table High (EMACHASHTBLH)** and the **Ethernet MAC Hash Table Low (EMACHASHTBLL)** for desired filtering options.
5. Write to the **Ethernet MAC Configuration Register (EMACCFG)** to configure the operating mode and enable the transmit operation.
6. Program Bit 15 (**PS**) and Bit 11 (**DM**) of the **EMACCFG** register based on the line status received or read from the PHY status register after auto-negotiation.
7. Write to the **Ethernet MAC DMA Operation Mode (EMACDMAOPMODE)** register to set Bits 13 and 1 to start transmission and reception.
8. Write to the **EMACCFG** register to enable the receive operation.

The Transmit and Receive engines enter the Running state and attempt to acquire descriptors from the respective descriptor lists. The Receive and Transmit engines then begin processing Receive and Transmit operations. The Transmit and Receive processes are independent of each other and can be started or stopped separately.

24.5 Ethernet PHY

The integrated PHY supports 10Base-T and 100Base-TX signaling. It integrates all the physical-layer functions needed to transmit and receive data on standard twisted-pair cables. The PHY directly interfaces to the integrated Media Access Controller (MAC).

The Ethernet PHY uses mixed-signal processing to perform equalization, data recovery, and error correction to achieve robust operation over CAT5 twisted-pair wiring. It not only meets the requirements of IEEE 802.3, but maintains high margins in terms of alien cross-talk. The following highlights the features of the PHY module:

- Cable Diagnostics
- Programmable Fast Link Down Modes
- Auto-MDIX for 10/100Mbps
- Energy Detection Mode
- Serial Management Interface
- IEEE 802.3u Auto-Negotiation and Parallel Detection
- IEEE 802.3u ENDEC, 10Base-T Transceivers and Filters

- IEEE 802.3u PCS, 100Base-TX Transceivers
- Integrated ANSI X3.263 Compliant TP-PMD Physical Sublayer with Adaptive Equalization and Baseline Wander Compensation
- Three programmable LEDs that support detection of Link OK, 10/100Mbs activity, TX/RX transfers, collisions and full duplex mode

24.5.1 Integrated PHY Block Diagram

The following figure shows the internal PHY integration. Note that the reference clock input comes from an external 25 MHz \pm 50 ppm crystal or oscillator connected to the MOSC signals.

Figure 24-15. Integrated PHY Diagram

24.5.2 Functional Description

The following sections describe the functional characteristics of the integrated PHY.

24.5.2.1 Auto-Negotiation

The Ethernet PHY can auto-negotiate to operate in 10Base-T or 100Base-TX. When the Ethernet PHY is enabled or on the deassertion of software reset, the **Ethernet MAC Peripheral Configuration Register (EMACPC)** register, offset 0xFC4, is configured such that auto-negotiation is enabled and the auto negotiation mode (ANMODE) bit field is programmed to 10Base-T, Half/Full-Duplex 100Base-TX, Half/Full-Duplex. With auto-negotiation enabled, the PHY negotiates with the link partner to determine the speed and duplex mode with which to operate. If the link partner is unable to auto-negotiate, the PHY goes into parallel-detect mode to determine the speed of the link partner. Under parallel-detect mode, the duplex mode is fixed at half-duplex. The PHY supports four different Ethernet protocols (10Mbs Half-Duplex, 10Mbs Full-Duplex, 100Mbs Half-Duplex, and 100Mbs Full-Duplex). Auto-Negotiation selects the highest performance protocol based on the advertised ability of the Link Partner. If a different auto-negotiation configuration is required other than the reset initialization values, the application can customize the configuration of the ANEN bit and ANMODE bit field as described in “Initialization and Configuration” on page 1653. The values of ANEN and ANMODE determine whether the PHY is forced into a specific mode, or if Auto-negotiation advertises a specific ability (or abilities) as listed in Table 24-33 on page 1648 and Table 24-34 on page 1648:

Table 24-33. Forced Mode Configurations

ANEN value	ANMODE	Forced Mode
0	0x0	10Base-T, Half-Duplex
0	0x1	10Base-T, Full-Duplex
0	0x2	100Base-TX, Half-Duplex
0	0x3	100Base-TX, Full-Duplex

Table 24-34. Advertised Mode Configurations

ANEN value	ANMODE	Advertised Mode
1	0x0	10Base-T, Half/Full-Duplex
1	0x1	100Base-TX, Half/Full-Duplex
1	0x2	10Base-T, Half Duplex 100Base-TX, Half Duplex
1	0x3	10Base-T, Half/Full-Duplex 100Base-TX, Half/Full-Duplex

24.5.2.2 Auto-MDIX

The PHY automatically determines whether or not it needs to cross over between pairs so that an external crossover cable is not required. If the PHY communicates with a device that implements MDI/MDIX crossover, a random algorithm as described in IEEE 802.3 determines which device performs the crossover. Auto-MDIX is enabled by default at reset. If a different auto-MDIX configuration is required other than the reset initialization, the application can customize the configuration as described in “Initialization and Configuration” on page 1653. Neither Auto-Negotiation nor Auto-MDIX is required to be enabled in forcing crossover of the MDI pairs. Auto-MDIX can be used in the forced 100Base-TX mode. Because in modern networks all the nodes are 100Base-TX, having the Auto-MDIX working in the forced 100Base-TX mode resolves the link faster without the need for the long Auto-Negotiation period.

24.5.2.3 Isolate Mode

The PHY can be put into Isolate mode by writing ISOLATE bit of the **Ethernet PHY Basic Mode Control - MR0 (EPHYBMR)** register, address 0x000. When in the Isolate mode, the PHY does not respond to packet data present at the internal interface to the Ethernet MAC. When in isolate mode, the PHY continues to respond to all management transactions and the PMD output pair does not transmit packet data, but continues to source 100Base-TX scrambled idles or 10Base-T normal link pulses. The PHY can auto-negotiate or parallel detect on the receive signal at the PMD input pair. A valid link can be established for the receiver even when the PHY is in Isolate mode.

24.5.2.4 LED Interface

The PHY supports three configurable Light Emitting Diode (LED) pins to indicate link status of a port. The **Ethernet PHY LED Configuration - MR37 (EPHYLEDCFG)** register, address 0x025 can be used to assign different functions to each LED. Each LED can be configured to be active during one of these events:

- Link OK (0x0)
- RX/TX Activity (0x1)
- TX Activity (0x2)
- RX Activity (0x3)

- Collision (0x4)
- 100-BASE TX speed (0x5)
- 10-Base TX speed (0x6)
- Full Duplex (0x7)
- Link OK/Blink on TX/RX Activity (0x8)

At reset, LED0 is initialized to display Link OK and LED1 and LED 2 are initialized to the RX/TX activity encoding. The blink rate of the LEDs can be set by programming the **BLINKRATE** bit field of the **Ethernet PHY LED Control - MR24 (EPHYLEDCR)** register, address 0x018

24.5.2.5 PHY Address

The integrated PHY's address is 0x00. To access the integrated PHY registers through the internal MAC's MDIO interface, the **PLA** bit field of the **Ethernet MAC MII Address (EMACMIIADDR)** register must be 0x00 and the **MII** field should be programmed to the desired address value.

24.5.2.6 Serial Management Interface

The Ethernet MAC module has the capability of programming the integrated PHY registers and extended registers through an internal Serial Management Interface (SMI). The SMI is compatible with IEEE802.3-2002 clause 22.

The SMI includes an MDC management clock input and management MDIO data pin to the Ethernet PHY. The internal MDC clock is sourced by the system clock and then divided down to the required 2.5 MHz maximum clock frequency by setting the **CR** bit in the **Ethernet MAC MII Address (EMACMIIADDR)** register. The MDC is not expected to be continuous, and can be turned off by the external management entity when the bus is idle. The MDIO is sourced by the integrated MAC and by the PHY. The data on the MDIO pin is latched on the rising edge of the MDC clock. The PHY's physical address is 0x00.

24.5.2.7 Extended Address Space Access

The PHY SMI function supports read/write accesses to the extended register set using **Ethernet PHY Register Control - MR13 (EPHYREGCTL)** register and the **Ethernet PHY Address or Data - MR14 (EPHYADDR)** registers. Accessing the standard register set, MDIO registers 0 to 31, can be performed using the normal direct MDIO access or the indirect method, except for the **EPHYREGCTL (0x00D)** and the **EPHYADDR (0x00E)** which can be accessed only using the normal MDIO transaction. The SMI function ignores indirect accesses to these registers.

The **EPHYREGCTL** register is the MDIO Manageable MMD access control. In general, register **EPHYREGCTL[4:0]** is the device address DEVAD that directs any accesses of **EPHYADDR** register to the appropriate MMD. Specifically, the PHY uses the vendor specific DEVAD [4 : 0] = 0xF for accesses. All accesses through registers **EPHYREGCTL** and **EPHYADDR** registers should use this DEVAD. Transactions with other DEVAD are ignored. The **EPHYREGCTL[15:14]** register holds the access function:

- **EPHYREGCTL[15:14] = 0x0**: A write to **EPHYADDR** modifies the extended register set address register. This address register must be initialized in order to access any of the registers within the extended register set.

- **EPHYREGCTL[15:14] = 0x1:** A read/write to **EPHYADDR** operates on the register within the extended register set selected (pointed to) by the value in the address register. The address register contents (pointer) remain unchanged.
- **EPHYREGCTL[15:14] = 0x2:** A read/write to **EPHYADDR** operates on the register within the extended register set selected (pointed to) by the value in the address register. After that access is complete, for both reads and writes, the value in the address register is incremented.
- **EPHYREGCTL[15:14] = 0x3:** A read/write to **EPHYADDR** operates on the register within the extended register set selected (pointed to) by the value in the address register. After that access is complete, for write accesses only, the value in the address register is incremented. For read accesses, the value of the address register remains unchanged.

The following sections describe how to perform operations on the extended register set using the **EPHYREGCTL** and **EPHYADDR** registers.

Write to PHY Registers

The following describes the steps to write to a PHY register.

1. Check the **MIIB** bit in the **EMACMIIADDR** register to identify if the MII interface is busy. When the **MIIB** bit is 0, the MII interface is available to write to the PHY registers.
2. Write the data to be written to the PHY register in the **EMACMIIDATA** register.
3. Initiate write by programming the **EMACMIIADDR** register fields as follows:
 - **PLA:** Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - **MII:** Address of the PHY register to be written.
 - **CR:** Clock Reference for the MDIO interface.
 - **MIIW:** Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - **MIIB:** MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.

Write to Extended PHY Registers

The following describes the steps to write to an extended PHY register.

1. Check the **MIIB** bit in the **EMACMIIADDR** register to identify if the MII interface is busy. When the **MIIB** bit is 0, the MII interface is available to write to the PHY registers.
2. The **EMACMIIDATA** register should be written with the value to be passed into the **EPHYREGCTL** register. The **EPHYREGCTL** register is used for extended PHY register accesses. The **DEVAD** field of the **EPHYREGCTL** register identifies the device address, which is 0x1F, for the integrated PHY. The **FUNC** field of the **EPHYREGCTL** register should be set to 0x0 to indicate a write to an extended register address.
3. Initiate write by programming the **EMACMIIADDR** register fields as follows:
 - **PLA:** Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.

- MII: Address of the PHY register to be written. In this case, it should be the address of the **EPHYREGCTL** register, 0xD.
 - CR: Clock Reference for the MDIO interface.
 - MIIW: Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - MIIB: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.
4. Check the MIIB bit in the **EMACMIIADDR** register to identify if the MII interface is busy. When the MIIB bit is 0, the MII interface is available to write to the PHY registers.
 5. The **EMACMIIDATA** register should be written with the address of the extended register to be accessed. This value is written to the **EPHYADDR** register.
 6. Initiate write by writing the **EMACMIIADDR** register fields:
 - PLA: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - MII: Address of the PHY register to be written. In this case, it should be the address of the **EPHYADDR** register, 0xE.
 - CR: Clock Reference for the MDIO interface.
 - MIIW: Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - MIIB: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.
 7. Check the MIIB bit in the **EMACMIIADDR** register to identify if the MII interface is busy. When the MIIB bit is 0, the MII interface is available to write to the PHY registers.
 8. The **EMACMIIDATA** register should be written with the value to be passed into the **EPHYREGCTL** register. The DEVAD field of the **EPHYREGCTL** register identifies the device address, which is 0x1F, for the integrated PHY. The FUNC field of the **EPHYREGCTL** register should be set to 0x1 to indicate a write to an extended register address with no increment.
 9. Initiate write by writing the **EMACMIIADDR** register fields:
 - PLA: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - MII: Address of the PHY register to be written. In this case, it should be the address of the **EPHYADDR** register, 0xD.
 - CR: Clock Reference for the MDIO interface.
 - MIIW: Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - MIIB: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.

10. Check the **MIIIB** bit in the **EMACMIIADDR** register to identify if the MII interface is busy. When the **MIIIB** bit is 0, the MII interface is available to write to the PHY registers.
11. The **EMACMIIDATA** register should be programmed with the data to be written to the **EPHYADDAR** register which is transferred to the previously selected extended PHY register.
12. Initiate write by writing the **EMACMIIADDR** register fields:
 - PLA: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - MII: Address of the PHY register to be written. In this case, it should be the address of the **EPHYADDAR** register, 0xD.
 - CR: Clock Reference for the MDIO interface.
 - MIIW: Write Initiation. This bit is set to 1 to indicate that a write operation is to be executed.
 - MIIIB: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a write operation. The EMAC clears this bit when the write has been transmitted.

Read from PHY Registers

The following describes the steps to read from an extended PHY register.

1. Check the **MIIIB** bit in the **EMACMIIADDR** register to identify if the MII interface is busy. When the **MIIIB** bit is 0, the MII interface is available to read to the PHY registers.
2. Initiate the read by writing the **EMACMIIADDR** register fields:
 - PLA: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - MII: Register address of PHY register to be written.
 - CR: Clock Reference for the MDIO interface.
 - MIIW: Write/Read Initiation. This bit is programmed to a 0 to indicate that a read operation is to be executed.
 - MIIIB: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a read operation. The EMAC clears this bit when the write has been transmitted.
3. Wait for the MII interface to complete the read by polling the **MIIIB** bit.
4. When the **MIIIB** is clear, read the contents of the **EMACMIIDATA** register.

Read from Extended PHY Registers

The following describes the steps to read from an extended PHY register.

1. Check the **MIIIB** bit in the **EMACMIIADDR** register to identify if the MII interface is busy. When the **MIIIB** bit is 0, the MII interface is available to read to the PHY registers.
2. Initiate the read by writing the **EMACMIIADDR** register fields:

- PLA: Physical Layer Address of the PHY. The integrated PHY's address is 0x0. The values 0x1 to 0x1F are available for external PHYs.
 - MII: Register address of PHY register to be written.
 - CR: Clock Reference for the MDIO interface.
 - MIW: Write/Read Initiation. This bit is programmed to a 0 to indicate that a read operation is to be executed.
 - MIIB: MII Busy. This bit is set to 1 to indicate that the MII is now busy with a read operation. The EMAC clears this bit when the write has been transmitted.
3. Wait for the write to complete by polling the MIIB bit.
 4. When the MIIB is clear, read the contents of the **EMACMIIDATA** register.

24.5.3 Initialization and Configuration

The following sections describe the hardware and software configuration required to set up the Ethernet Controller.

24.5.3.1 Interface Configuration

Figure 24-16 on page 1653 shows the proper method for interfacing the Ethernet Controller to a 10/100BASE-T Ethernet jack.

Figure 24-16. Interface to Ethernet Jack

NOTE: The 0.1mF capacitors on pins 2 and 7 of the HX1188FNL should be located near the physical pins of the transformer.

The Ethernet PHY is designed to work with transformers that meet the IEEE 802.3 standard. To utilize the Auto-MDIX (AMDIX) capability of the Ethernet PHY, a symmetrical transformer is

recommended. The Pulse HX1188 transformer has been tested and is known to successfully interface to the Ethernet PHY.

Note: If the PHY is not to be used, then the EN0RXIN/EN0TX0N EN0RXIP/EN0TX0P pair should be left unconnected and the R_{BIA}S pin should be unconnected as well.

Note: When entering hibernation in VDD3ON mode, the supply rails to the Ethernet resistors R1, R2, R3, R4 found in Figure 24-16 on page 1653 must be switched off.

24.5.3.2 Functional Configuration and Initialization

After reset, when the EMAC is powered and enabled, the **EMACPC** default register reset value is sampled and used to configure the PHY. The results of this configuration can also be read in the following EPHY registers:

- **EPHYBMCR** register (MR0)
- **EPHYCFG1** register (MR9)
- **EPHYCFG2** register (MR10)
- **EPHYCFG3** register (MR11)
- **EPHYCTL** register (MR25)

The mappings of the **EMACPC** register bits to the PHY register and bits are as follows:

Table 24-35. EMACPC to PHY Register Mapping

EMACPC Register Bit	Corresponding PHY Register	Corresponding PHY Bit (Bit No.)
PHYEXT	N/A	N/A
DIGRESTART	N/A	N/A
NIBDETDIS	EPHYCFG2	ODDNDETDIS (1)
RXERIDLE	EPHYCFG2	RXERRIDLE (2)
ISOMILL	EPHYCFG2	ISOMILL (3)
LRR	EPHYCFG1	LLR (7)
TDRRUN	EPHYCFG1	TDRAR (8)
FASTLDMODE	EPHYCFG3	FLDWNM (4:0)
POLSWAP	EPHYCFG3	POLSWAP (7)
MDISWAP	EPHYCFG3	MDIMDIKS (6)
RBSTMDIX	EPHYCFG1	RAMDIX (5)
FASTMDIX	EPHYCFG1	FAMDIX (6)
MDIXEN	EPHYCTL	AUTOMDI (15)
FASTRXDV	EPHYCFG1	FRXDVDET (1)
FASTLUPD	EPHYCFG2	FLUPPD (6)
EXTFD	EPHYCFG2	EXTFD (5)
FASTANEN	EPHYCFG1	FASTANEN (4)
FASTANSEL	EPHYCFG1	FANSEL (3:2)
ANEN	EPHYBMCR	ANEN
ANMODE	N/A	N/A
PHYHOLD	N/A	N/A

The MAC module and registers are enabled and powered at reset. When reset has completed, the application should enable the clock to the Ethernet MAC by setting the R0 bit in the **Ethernet Controller Run Mode Clock Gating Control (RCGCEMAC)** register at System Control Module offset 0x69C. To enable the PHY with its default interface configuration as defined by the **Ethernet MAC Peripheral Configuration Register (EMACPC)** register, do the following:

1. To hold the PHY from transmitting energy on the line during configuration, set the **PHYHOLD** bit to 1 in the **EMACPC** register.
2. Enable the clock to the PHY module by writing 0x0000.0001 to the **Ethernet PHY Run Mode Clock Gating Control (RCGCEPHY)** register at offset 0x630 and then delay for 30 clock cycles

If a custom configuration of the PHY is required, the application can program the configuration registers after reset. The steps for custom configuration are as follows:

1. To hold the PHY from transmitting energy on the line during configuration, set the **PHYHOLD** bit to 1 in the **EMACPC** register.
2. Enable the clock to the PHY module by writing 0x0000.0001 to the **Ethernet PHY Run Mode Clock Gating Control (RCGCEPHY)** register at offset 0x630 and then delay for 30 clock cycles
3. Enable power to the EPHY Module by writing 0x0000.0001 to the **Ethernet PHY Run Mode Clock Gating Control (RCGCEPHY)** register at offset 0x69C.
4. Once the **Ethernet PHY Peripheral Ready (PREPHY)** register reads 0x0000.0001, software can write the **EMACPC** register with the required value.
5. After software configuration is complete, the application must set the **DONE** bit in the **Ethernet PHY Configuration 1 (EPHYCFG1)** register at offset 0x009.

Note: If a software reset is asserted to the PHY afterwards through the **SREPHY** register, the custom configuration is lost and the steps described above must be repeated.

24.6 Register Map

Table 24-36 on page 1656 lists the Ethernet Controller MAC and PHY registers. For the MAC registers, the offset listed is a hexadecimal increment to the MAC base address of 0x400E.C000. PHY registers are accessed through the **EMACMIIADDR** register thus the base address is n/a (not applicable) and noted as such above the register descriptions.

The *IEEE 802.3* standard specifies a register set for controlling and gathering status from the PHY layer. The registers are collectively known as the MII Management registers. Table 24-36 on page 1656 also lists these MII Management registers for interfacing to the internal PHY. All addresses given are absolute and are written directly to the **MII** field of the **Ethernet MAC MII Address (EMACMIIADDR)** register, offset 0x010. The **PLA** value of the **EMACMIIADDR** register for the internal PHY is 0x00.

The **Ethernet MAC MII Address (EMACMIIADDR)** register, offset 0x010, is used to access MII Management registers on the external PHY device. The **PLA** field in the **EMACMIIADDR** register supports PHY addresses 1 to 31.

Table 24-36. Ethernet Register Map

Offset	Name	Type	Reset	Description	See page

24.7 Ethernet MAC Register Descriptions

This section lists and describes the MAC registers, in numerical order by address offset. Also see “Ethernet PHY Register Descriptions” on page 1781.

Register 1: Ethernet MAC Configuration (EMACCFG), offset 0x000

The **EMACCFG** register establishes receive and transmit operating modes. Note that the **TWOKPEN** bit is only applicable when the **JFEN** bit is 0.

Ethernet MAC Configuration (EMACCFG)

Base 0x400E.C000
Offset 0x000
Type RW, reset 0x0000.8000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description
31	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
30:28	SADDR	RW	0x0	<p>Source Address Insertion or Replacement Control</p> <p>Bit 30 specifies whether MAC address 0 or 1 registers are used during insertion or replacement for all transmitted frames. Thus for encodings 0x2-0x3, where the most significant bit is 0, the Ethernet MAC Address 0 registers are used.</p> <p>For encodings 0x6-0x7, the Ethernet MAC Address 1 registers are used.</p> <p>Bits [29:28] indicate insertion or replacement. If the value is 0x2 insertion is indicated and if the value is 0x3 replacement is indicated.</p>

Value	Description
0x0-0x1	reserved
0x2	The Ethernet MAC inserts the content of the Ethernet MAC Address 0 (EMACADDR0x) registers in the SA field of all transmitted frames.
0x3	The Ethernet MAC replaces the content of the Ethernet MAC Address 0 (EMACADDR0x) registers in the SA field of all transmitted frames.
0x4-0x5	reserved
0x6	The MAC inserts the content of the Ethernet MAC Address 1 (EMACADDR1x) registers in the source address (SA) field for all transmitted frames.
0x7	The MAC replaces the content of the Ethernet MAC Address 1(EMACADDR1x) registers in the source address (SA) field for all transmitted frames.

Note: Changes in this field take effect only on the start of a frame. If a write of this field occurs while a frame is being transmitted, only the subsequent frame can use the updated value, and the current frame does not.

Bit/Field	Name	Type	Reset	Description						
27	TWOKOPEN	RW	0x0	<p>IEEE 802.3as Support for 2K Packets</p> <p>When set, the MAC considers all frames, up to 2,000 bytes in length, as normal packets. This bit is only valid when the <code>JFEN</code> bit is set to 0.</p> <p>When <code>JFEN</code> is set, configuring <code>TWOKOPEN</code> has no effect on Giant Frame status.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>If the <code>JFEN</code> bit is clear, the MAC considers all received frames larger than 1,518 bytes (1,522 bytes tagged) as Giant Frames.</td></tr> <tr> <td>1</td><td>Frames up to 2 KB are considered normal packets. If the <code>JFEN</code> bit is clear, the MAC considers all received frames larger than 2K bytes as Giant frames.</td></tr> </tbody> </table>	Value	Description	0	If the <code>JFEN</code> bit is clear, the MAC considers all received frames larger than 1,518 bytes (1,522 bytes tagged) as Giant Frames.	1	Frames up to 2 KB are considered normal packets. If the <code>JFEN</code> bit is clear, the MAC considers all received frames larger than 2K bytes as Giant frames.
Value	Description									
0	If the <code>JFEN</code> bit is clear, the MAC considers all received frames larger than 1,518 bytes (1,522 bytes tagged) as Giant Frames.									
1	Frames up to 2 KB are considered normal packets. If the <code>JFEN</code> bit is clear, the MAC considers all received frames larger than 2K bytes as Giant frames.									
26	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
25	CST	RW	0x0	<p>CRC Stripping for Type Frames</p> <p>When set, the last four bytes (Frame Check Sequence FCS) of all frames of Ether type ((Length/Type field greater than or equal to 0x0600) are removed before forwarding the frame to the application.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No bytes are removed.</td></tr> <tr> <td>1</td><td>The last four bytes are removed before forwarding.</td></tr> </tbody> </table>	Value	Description	0	No bytes are removed.	1	The last four bytes are removed before forwarding.
Value	Description									
0	No bytes are removed.									
1	The last four bytes are removed before forwarding.									
24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
23	WDDIS	RW	0x0	<p>Watchdog Disable</p> <p>When this bit is set, the MAC disables the internal watchdog counter on the receiver. The MAC can receive frames of up to 16,384 bytes.</p> <p>When this bit is cleared, the MAC does not allow more than 2,048 bytes (10,240 if <code>JFEN</code> is set to 1) of the frame being received. The MAC cuts off any bytes received after 2,048 bytes.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Watchdog counter enabled.</td></tr> <tr> <td>1</td><td>Watchdog counter disabled.</td></tr> </tbody> </table>	Value	Description	0	Watchdog counter enabled.	1	Watchdog counter disabled.
Value	Description									
0	Watchdog counter enabled.									
1	Watchdog counter disabled.									
22	JD	RW	0x0	<p>Jabber Disable</p> <p>When this bit is set, the MAC disables the jabber counter on the transmitter. The MAC can transfer frames of up to 16,384 bytes.</p> <p>When this bit is clear, the MAC stops transmission if the application sends out more than 2,048 bytes of data (10,240 if <code>JFEN</code> is set to 1).</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Jabber counter enabled.</td></tr> <tr> <td>1</td><td>Jabber counter disabled.</td></tr> </tbody> </table>	Value	Description	0	Jabber counter enabled.	1	Jabber counter disabled.
Value	Description									
0	Jabber counter enabled.									
1	Jabber counter disabled.

Value	Description																					
0	10 Mbps																					
1	100 Mbps																					

Bit/Field	Name	Type	Reset	Description						
13	DRO	RW	0	<p>Disable Receive Own</p> <p>When this bit is set, the MAC disables the reception of frames while transmitting in half-duplex mode.</p> <p>When this bit is clear, the MAC receives all packets that are given by the PHY while transmitting.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>All packets are received by MAC.</td></tr> <tr> <td>1</td><td>Disable reception of frames.</td></tr> </tbody> </table> <p>Note: This bit is not applicable if the MAC is operating in full-duplex mode.</p>	Value	Description	0	All packets are received by MAC.	1	Disable reception of frames.
Value	Description									
0	All packets are received by MAC.									
1	Disable reception of frames.									
12	LOOPBM	RW	0	<p>Loopback Mode</p> <p>When this bit is set, the MAC operates in the loopback mode at the MII. The MII Receive clock input, EN0RXCK, is required for the loopback to work properly, because the Transmit clock is not looped-back internally.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>MAC does not operate in loopback mode.</td></tr> <tr> <td>1</td><td>MAC operates in loopback mode.</td></tr> </tbody> </table>	Value	Description	0	MAC does not operate in loopback mode.	1	MAC operates in loopback mode.
Value	Description									
0	MAC does not operate in loopback mode.									
1	MAC operates in loopback mode.									
11	DUPM	RW	0	<p>Duplex Mode</p> <p>When this bit is set, the MAC operates in the full-duplex mode where it can transmit and receive simultaneously.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>MAC does not operate in full-duplex mode.</td></tr> <tr> <td>1</td><td>MAC operates in full-duplex mode.</td></tr> </tbody> </table>	Value	Description	0	MAC does not operate in full-duplex mode.	1	MAC operates in full-duplex mode.
Value	Description									
0	MAC does not operate in full-duplex mode.									
1	MAC operates in full-duplex mode.									
10	IPC	RW	0x0	<p>Checksum Offload</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The checksum offload function in the receiver is disabled and the corresponding PCE and IP HCE status bits in the frame status are always cleared.</td></tr> <tr> <td>1</td><td> <p>Checksum Offload Enable</p> <p>Setting this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking.</p> </td></tr> </tbody> </table>	Value	Description	0	The checksum offload function in the receiver is disabled and the corresponding PCE and IP HCE status bits in the frame status are always cleared.	1	<p>Checksum Offload Enable</p> <p>Setting this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking.</p>
Value	Description									
0	The checksum offload function in the receiver is disabled and the corresponding PCE and IP HCE status bits in the frame status are always cleared.									
1	<p>Checksum Offload Enable</p> <p>Setting this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking.</p>									

Bit/Field	Name	Type	Reset	Description										
9	DR	RW	0x0	<p>Disable Retry</p> <p>When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current frame transmission and reports a frame abort with excessive collision error in the transmit frame status.</p> <p>When this bit is cleared, the MAC attempts retries based on the settings of the BL field (Bits [6:5]).</p> <p>Note: This bit is only applicable in half-duplex mode.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>MAC retries transmissions based on BL bit field.</td></tr> <tr> <td>1</td><td>Only one transmission is attempted by the MAC.</td></tr> </tbody> </table>	Value	Description	0	MAC retries transmissions based on BL bit field.	1	Only one transmission is attempted by the MAC.				
Value	Description													
0	MAC retries transmissions based on BL bit field.													
1	Only one transmission is attempted by the MAC.													
8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										
7	ACS	RW	0x0	<p>Automatic Pad or CRC Stripping</p> <p>When this bit is set, the MAC strips the Pad or Frame Check Sequence (FCS) field on the incoming frames only if the value of the length field is less than 1,536 bytes. All received frames with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field.</p> <p>When this bit is cleared, the MAC passes all incoming frames, without modifying them, to the Host.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>All frames are passed to host unmodified.</td></tr> <tr> <td>1</td><td>MAC strips FCS field if value of length field is less than 1,536 bytes.</td></tr> </tbody> </table>	Value	Description	0	All frames are passed to host unmodified.	1	MAC strips FCS field if value of length field is less than 1,536 bytes.				
Value	Description													
0	All frames are passed to host unmodified.													
1	MAC strips FCS field if value of length field is less than 1,536 bytes.													
6:5	BL	RW	0x0	<p>Back-Off Limit</p> <p>The Back-Off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. The random integer r takes the value in the range $0 \leq r < 2^k$</p> <p>The value of k is programmed in the encodings below and is dependent on the retransmission attempt number, n. This bit is applicable only in the half-duplex mode.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0x0</td><td>$k = \min(n, 10)$, where k is the lowest value when evaluating n or 10.</td></tr> <tr> <td>0x1</td><td>$k = \min(n, 8)$, where k is the lowest value when evaluating n or 8.</td></tr> <tr> <td>0x2</td><td>$k = \min(n, 4)$, where k is the lowest value when evaluating n or 4.</td></tr> <tr> <td>0x3</td><td>$k = \min(n, 1)$, where k is the lowest value when evaluating n or 1.</td></tr> </tbody> </table>	Value	Description	0x0	$k = \min(n, 10)$, where k is the lowest value when evaluating n or 10.	0x1	$k = \min(n, 8)$, where k is the lowest value when evaluating n or 8.	0x2	$k = \min(n, 4)$, where k is the lowest value when evaluating n or 4.	0x3	$k = \min(n, 1)$, where k is the lowest value when evaluating n or 1.
Value	Description													
0x0	$k = \min(n, 10)$, where k is the lowest value when evaluating n or 10.													
0x1	$k = \min(n, 8)$, where k is the lowest value when evaluating n or 8.													
0x2	$k = \min(n, 4)$, where k is the lowest value when evaluating n or 4.													
0x3	$k = \min(n, 1)$, where k is the lowest value when evaluating n or 1.													

Bit/Field	Name	Type	Reset	Description						
4	DC	RW	0x0	<p>Deferral Check</p> <p>When this bit is set, the deferral check function is enabled in the MAC. When the transmit state machine is deferred for more than 24,288 bit times, the MAC issues a Frame Abort status, and sets the excessive deferral error bit (EXDEFF) in the MAC MMC Transmit Interrupt (EMACMMCTXRIS) Register.</p> <p>If the Jumbo frame mode (JFEN) is enabled, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on the MII.</p> <p>The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and then the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0 and it is restarted.</p> <p>When this bit is clear, the deferral check function is disabled and the EMAC defers until the CRS signal goes inactive.</p> <p>Note: This bit is only applicable in half-duplex mode.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Deferral check function is disabled.</td></tr> <tr> <td>1</td><td>Deferral check function is enabled.</td></tr> </tbody> </table>	Value	Description	0	Deferral check function is disabled.	1	Deferral check function is enabled.
Value	Description									
0	Deferral check function is disabled.									
1	Deferral check function is enabled.									
3	TE	RW	0x0	<p>Transmitter Enable</p> <p>When this bit is set, the transmit state machine of the MAC is enabled for transmission on the MII.</p> <p>When this bit is clear, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>MAC transmit state machine is disabled.</td></tr> <tr> <td>1</td><td>MAC transmit state machine is enabled.</td></tr> </tbody> </table>	Value	Description	0	MAC transmit state machine is disabled.	1	MAC transmit state machine is enabled.
Value	Description									
0	MAC transmit state machine is disabled.									
1	MAC transmit state machine is enabled.									
2	RE	RW	0x0	<p>Receiver Enable</p> <p>When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the MII.</p> <p>When this bit is clear, the MAC receive state machine is disabled after completion of the reception of the current frame, and does not receive any further frames from the MII.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>MAC receive state machine is disabled.</td></tr> <tr> <td>1</td><td>MAC receive state machine is enabled.</td></tr> </tbody> </table>	Value	Description	0	MAC receive state machine is disabled.	1	MAC receive state machine is enabled.
Value	Description									
0	MAC receive state machine is disabled.									
1	MAC receive state machine is enabled.									

Bit/Field	Name	Type	Reset	Description
1:0	PRELEN	RW	0x0	Preamble Length for Transmit Frames These bits control the number of preamble bytes that are added to the beginning of every Transmit frame. The preamble reduction occurs only when the MAC is operating in the full-duplex mode.
Value Description				
0x0 7 bytes of preamble				
0x1 5 bytes of preamble				
0x2 3 bytes of preamble				
0x3 reserved				

Register 2: Ethernet MAC Frame Filter (EMACFRAMEFLTR), offset 0x004

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

Value	Description									
0	Incoming frames are filtered.									
1	All incoming frames are passed.									

Register 3: Ethernet MAC Hash Table High (EMACHASHTBLH), offset 0x008

The 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the Destination Address (DA) in the incoming frame is passed through the CRC logic, and the upper 6 bits of the CRC register are used to index the contents of the Hash table. The most significant bit determines the register to be used (**Ethernet MAC Hash Table High (EMACHASHTBLH)** or **Ethernet MAC Hash Table Low (MACHASHTBLL)**), and the other five bits determine which bit within the register. A hash value of 5b'00000 selects bit 0 of the selected register, and a value of 5b'11111 selects bit 31 of the selected register.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in Step 1.
3. Take the upper 6 bits from the value obtained in Step 2.

For example, if the DA of the incoming frame is received as 0x1F52419CB6AF, then the internally calculated 6-bit Hash value is 0x2C and Bit 12 of **EMACHASHTBLH** register is checked for filtering. If the DA of the incoming frame is received as 0xA00A98000045, then the calculated 6-bit Hash value is 0x07 and Bit 7 of Hash Table Low register is checked for filtering.

If the corresponding bit value of the register is 0x1, the frame is accepted. Otherwise, it is rejected. If the **PM** (Pass All Multicast) bit is set in the **Ethernet MAC Frame Filter (EMACFRAMEFLTR)** register, then all multicast frames are accepted regardless of the multicast hash values.

15:0	DATA	RW	0x0	MII Data This field contains the 16-bit data value read from the PHY after a management read operation or the 16-bit data value to be written to the PHY before a management write operation.

Register 7: Ethernet MAC Flow Control (EMACFLOWCTL), offset 0x018

The **Ethernet MAC Flow Control (EMACFLOWCTL)** register controls the generation and reception of the control (pause command) frames by the MAC's Flow control module. A write to a register with the FCBBPA (bit 0) set to 1 triggers the Flow Control block to generate a pause control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the pause time (PT) value from this register is used in the pause time field of the control frame. The FCBBPA bit is cleared by the hardware once the control frame is transferred onto the cable. The Host must make sure that the busy bit is clear before writing to the register.

Ethernet MAC Flow Control (EMACFLOWCTL)

Base 0x400E.C000
Offset 0x018
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	PT	RW	0x0	Pause Time This field holds the value to be used in the pause time field in the transmit control frame. For example, if these bits are set to 0x0100 then 256 slot times are used in the Pause Time field in the transmit control frame.
15:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	DZQP	RW	0	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the Zero-Quanta Pause Control frames on the deassertion of the flow-control signal from the FIFO layer. When this bit is reset, normal operation with automatic Zero-Quanta Pause Control frame generation is enabled. Value Description 0 Automatic Zero-Quanta Pause Control generation is enabled. 1 Automatic Zero-Quanta Pause Control generation is disabled.
6	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

1	In the full-duplex mode, the MAC enables the flow control operation to transmit pause frames. In half-duplex mode, the MAC enables the back-pressure operation.													

Bit/Field	Name	Type	Reset	Description
0	FCBBPA	RW	0	<p>Flow Control Busy or Back-pressure Activate</p> <p>In the full-duplex mode, this bit should be read as 0x0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 0x1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 0x0. The EMACFLOWCTL register should not be written to until this bit is cleared.</p>
Value Description				
0 No effect				
1 In the full-duplex mode, a pause control frame is enabled. In half-duplex mode, a back-pressure function is enabled if the TFE bit is set.				

Register 8: Ethernet MAC VLAN Tag (EMACVLANTG), offset 0x01C

The **Ethernet MAC VLAN Tag (MACVLANTG)** register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with the value 0x8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes.

Ethernet MAC VLAN Tag (EMACVLANTG)

Base 0x400E.C000
Offset 0x01C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	VTHM	RW	0	VLAN Tag Hash Table Match Enable
		Value	Description	
		0	The VLAN Hash Match operation is not performed.	
		1	The most significant four bits of the VLAN tag's CRC are used to index the content of the MAC VLAN Hash Table (EMACVLANHASH) register. A value of 1 in the EMACVLANHASH register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison.	
18	ESLV	RW	0	Enable S-VLAN
		Value	Description	
		0	The MAC transmitter does not recognize S-VLAN frames as valid VLAN tagged frames.	
		1	The MAC transmitter and receiver considers the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.	

Bit/Field	Name	Type	Reset	Description

Register 10: Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF), offset 0x028

This is the address through which the application writes or reads the remote wake-up frame filter registers. Note that to load values in the **Ethernet MAC Wake-up Frame Filter (EMACRWUFF)** register, the entire register must be written. The **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register is a pointer to eight wake-up frame filter registers. The **Ethernet MAC Remote Wake-Up Frame Filter (EMACRWUFF)** register is loaded by sequentially loading the eight register values. Eight sequential writes to this address programs all of the remote wake-up frame filter registers. Similarly, eight sequential reads from the **EMACRWUFF** register reads all wake-up frame registers.

Bit/Field	Name	Type	Reset	Description
31	WUPFRRST	RW	0	Wake-Up Frame Filter Register Pointer Reset
				Value Description
			0	No effect.
			1	Resets the MAC Remote Wake-Up Frame Filter (EMACRWUFF) register pointer to 0x0. It is automatically cleared after one clock cycle.
30:27	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
26:24	RWKPTR	RW	0	Remote Wake-Up FIFO Pointer
				This gives the current value (0 to 7) of the MAC Remote Wake-Up Frame Filter (EMACRWUFF) register pointer. The contents of the EMACRWUFF Register are transferred to the receive clock domain when a write occurs to that register when this pointer value equals 7.
23:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	GLBLUCAST	RW	0	Global Unicast
				Value Description
			0	No Effect.
			1	Enables any unicast packet filtered by the MAC Destination Address Filter (DAF) module's address recognition to be a wake-up frame.
8:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

3	CNTFREEZ	RW	0	<p>MMC Counter Freeze</p> <p>When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the RSTONRD bit set, then that counter is also cleared in this mode.</p> <p>Value Description</p> <ul style="list-style-type: none"> 0 MMC counters are updated when a frame is transmitted or received. 1 When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame.
2	RSTONRD	RW	0x0	<p>Reset on Read</p> <p>Value Description</p> <ul style="list-style-type: none"> 0 No effect. 1 MMC counters are reset to zero after a read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.

Bit/Field	Name	Type	Reset	Description
1	CNTSTPRO	RW	0	Counters Stop Rollover Value Description 0 No effect. 1 After reaching maximum value, the MMC counters do not roll over to zero.
0	CNTRST	RW	0x0	Counters Reset Value Description 0 No effect 1 All MMC counters are reset. This bit is cleared automatically after one clock cycle.

Register 24: Ethernet MAC MMC Receive Raw Interrupt Status (EMACMMCRXRIS), offset 0x104

The **MAC MMC Receive Interrupt (EMACMMCRXRIS)** register maintains the interrupts that are generated when the following happens:

- Receive statistic counters reach half of their maximum values (0x8000.0000 for 32-bit counter and 0x8000 for 16-bit counter).
- Receive statistic counters cross their maximum values (0xFFFF.FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When the Counter Stop Rollover (CNTSTPRO bit) in the **MAC MMC Control (EMACMMCCTRL)** register is set, interrupts are set but the counter remains at all-ones. The **EMACMMCRXRIS** register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

This operation is performed on all transmitted frames, irrespective of whether they already have a VLAN tag.	0x3	VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted frames (Bytes 13 and 14 are 0x8100/0x88a8).
Value	Description													
0x0	No VLAN tag deletion, insertion, or replacement													
0x1	VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted frames with VLAN tags.													
0x2	VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the frame after inserting the Type value (0x8100/0x88a8) in bytes 13 and 14. This operation is performed on all transmitted frames, irrespective of whether they already have a VLAN tag.													
0x3	VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted frames (Bytes 13 and 14 are 0x8100/0x88a8).													
				<p>Note: Changes to this field take effect only on the start of a frame. If you write this register field when a frame is being transmitted, only the subsequent frame can use the updated value, that is, the current frame does not use the updated value.</p>										
15:0	VLT	RW	0x0	<p>VLAN Tag for Transmit Frames</p> <p>This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority, Bit 12 is the CFI/DEI, and Bits[11:0] are the VLAN tag's VID field.</p>										

Register 37: Ethernet MAC VLAN Hash Table (EMACVLANHASH), offset 0x588

The 16-bit hash table is used for group address filtering based on VLAN tag when the VTHM bit of the **EMACVLANTG** register is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (enabled by ETV in the **EMACVLANTG** register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the **EMACVLANHASH** register. For example, a hash value of 0x8 selects bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper four bits from the value obtained in Step 2.

If the corresponding bit value of the register is 0x1, the frame is accepted. Otherwise, it is rejected.

31:0	TSS	RW	0x0	<p>Timestamp Second</p> <p>The value in this field indicates the time in seconds to be initialized or added to the system time.</p>

Register 43: Ethernet MAC System Time - Nanoseconds Update (EMACTIMNANOU), offset 0x714

This register along with the **EMACTIMSECU** register initializes or updates the system time maintained by the MAC. Both of these register must be written before setting the TSINIT or TSUPDT bits in the **EMACTIMSTCTRL** register.

Ethernet MAC System Time - Nanoseconds Update (EMACTIMNANOU)

Base 0x400E.C000

Offset 0x714

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31	ADDSUB	RW	0x0	Add or subtract time Value Description 0x0 The time value is added with the contents of the update register. 0x1 The time value is subtracted with the contents of the update register.
30:0	TSSS	RW	0x0	Timestamp Sub-Second The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When DGTLBIN in the EMACTIMSTCTRL register is set, each bit represents 1 ns and the programmed value should not exceed 0x3B9A.C9FF.

Register 44: Ethernet MAC Timestamp Addend (EMACTIMADD), offset 0x718

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit is set in the **EMACTIMSTCTRL** register). This register content is added to a 32-bit accumulator every slave clock cycle (MOSC source) and the system time is updated whenever the accumulator overflows.

Ethernet MAC Timestamp Addend (EMACTIMADD)

Base 0x400E.C000
Offset 0x718
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	TSAR	RW	0x0	Timestamp Addend Register This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

Register 45: Ethernet MAC Target Time Seconds (EMACTARGSEC), offset 0x71C

The **MAC Target Time Seconds (EMACTARGSEC)** register, along with the **MAC Target Time Nanoseconds (EMACTARGNANO)** register, is used to schedule an interrupt event.

Ethernet MAC Target Time Seconds (EMACTARGSEC)

Base 0x400E.C000
Offset 0x71C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	TSTR	RW	0x0	<p>Target Time Seconds Register</p> <p>This register stores the time in seconds. When the timestamp value matches or exceeds both the MAC Target Time Seconds (EMACTARGSEC) and MAC Target Time Nanoseconds (EMACTARGNANO) registers, then based on the TRGMODS0 bit field in the MAC PPS Control (EMACPPSCTRL), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled).</p>

Register 46: Ethernet MAC Target Time Nanoseconds (EMACTARGNANO), offset 0x720

The **MAC Target Time Seconds (EMACTARGSEC)** register, along with the **MAC Target Time Nanoseconds (EMACTARGNANO)** register, is used to schedule an interrupt event.

Ethernet MAC Target Time Nanoseconds (EMACTARGNANO)

Base 0x400E.C000
Offset 0x720
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31	TRGTBUSY	RW	0x0	<p>Target Time Register Busy</p> <p>This bit is set and cleared by the MAC.</p>
				Value Description
				0 The Ethernet MAC Target Time Seconds/Nanoseconds (EMACTARGSEC/EMACTARGNANO) registers are not busy.
				1 The Ethernet MAC Target Time Seconds/Nanoseconds (EMACTARGSEC/EMACTARGNANO) registers are busy. This bit is set when the PPSCTRL field in the EMACPPSCTRL register is programmed to 0x2 or 0x3 and the MAC is instructed to synchronize the EMACTARGSEC/EMACTARGNANO registers to the PTP clock domain.
				<p>Note: The EMACTARGSEC and EMACTARGNANO registers must not be updated when this bit is read as 1.</p>
30:0	TTSLO	RW	0x0	<p>Target Timestamp Low Register</p> <p>This register stores the time in (signed) nanoseconds. When the value of the timestamp matches both EMACTARGx registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGMODS0 field in the MAC PPS Control (EMACPPSCTRL) register.</p> <p>This value should not exceed 0x3B9A.C9FF when DGTLBIN is set in the EMACTIMSTCTRL register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.</p>

Register 47: Ethernet MAC System Time-Higher Word Seconds (EMACHWORDSEC), offset 0x724

This register is used to support the most significant 16-bits of the timestamp seconds value.

Ethernet MAC System Time-Higher Word Seconds (EMACHWORDSEC)

Base 0x400E.C000
Offset 0x724
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TSHWR	RW	0x0	<p>Target Timestamp Higher Word Register</p> <p>This field contains the most significant 16-bits of the timestamp seconds value. The register is directly written to initialize the value. This register is incremented when there is an overflow from the 32-bits of the System Time - Seconds register.</p>

Register 48: Ethernet MAC Timestamp Status (EMACTIMSTAT), offset 0x728

Ethernet MAC Timestamp Status (EMACTIMSTAT)

Base 0x400E.C000

Offset 0x728

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	TSTARGT	RO	0x0	Timestamp Target Time Reached
		Value	Description	
		0x0	Target Time has not been reached.	
		0x1	Indicates that the value of system time is greater or equal to the value specified in EMACTARGSEC (Target Time Seconds Register) and EMACTARGNANO (Target Time Nanoseconds Register).	
0	TSSOVF	RO	0x0	Timestamp Seconds Overflow
		Value	Description	
		0x0	No timestamp overflow has occurred.	
		0x1	Indicates the seconds value of the timestamp has overflowed beyond 0xFFFF.FFFF.	

Register 49: Ethernet MAC PPS Control (EMACPPSCTRL), offset 0x72C

This register is used to control the EN0PPS signal output.

Note: The PTP reference clock referred to below is MOSC clock in coarse update mode and in fine correction mode, is the clock tick at which the system time gets updated.

Ethernet MAC PPS Control (EMACPPSCTRL)

Base 0x400E.C000

Offset 0x72C

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:5	TRGMODS0	RO	0x0	Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (EMACTARGSEC and EMACTARGNANO) mode for the EN0PPS output signal:
		Value	Description	
		0x0	Indicates that the Target Time registers are programmed only for generating the interrupt event.	
		0x1	Reserved	
		0x2	Indicates that the Target Time registers are programmed for generating the interrupt event and starting or stopping the generation of the EN0PPS output signal.	
		0x3	Indicates that the Target Time registers are programmed only for starting or stopping the generation of the EN0PPS output signal. No interrupt is asserted.	
4	PPSEN0	RO	0x0	Flexible PPS Output Mode Enable
		Value	Description	
		0x0	Bits[3:0] function as PPS output frequency control (PPSCTRL).	
		0x1	Bits[3:0] function as PPS Command (PPSCMD).	

Bit/Field	Name	Type	Reset	Description
3:0	PPSCTRL	RW	0x0	

Bit/Field	Name	Type	Reset	Description														
				<p><code>EN0PPS</code> Output Frequency Control (PPSCTRL) or Command Control (PPSCMD)</p> <p>This bit field has two different functions depending on how the <code>PPSEN0</code> bit is set.</p> <p>If the <code>PPSEN0</code> bit is set to 0x0, this field functions as a PPS0 output frequency control (PPSCTRL), which controls the frequency of the output signal, <code>EN0PPS</code>. The default value of this field is 0x0 and the PPS output is one pulse every second.</p> <p>If the <code>PPSEN0</code> bit is 0x1, this field functions as a flexible output command control for the <code>EN0PPS</code> signal. Programming the PPSCTRL bit field with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits are cleared automatically. Software should ensure that these bits are programmed only when they are "all-zeros."</p>

Value	Description																											
	This command immediately stops the train of pulses initiated by the START pulse train command.																											
0x6	When the PPSEN0 bit = 0x0, the binary rollover is 64 Hz, and the digital rollover is 32 Hz. When the PPSEN0 bit = 0x1, cancel STOP pulse train. This command cancels the STOP pulse train at the time command if the programmed stop time has not elapsed. The EN0PPS pulse train becomes free-running on the successful execution of this command.																											
0x7	When the PPSEN0 bit = 0x0, the binary rollover is 128 Hz, and the digital rollover is 64 Hz. When the PPSEN0 bit = 0x1, this encoding is reserved.																											
0x8	When the PPSEN0 bit = 0x0, the binary rollover is 256 Hz, and the digital rollover is 128 Hz. When the PPSEN0 bit = 0x1, this encoding is reserved.																											
0x9	When the PPSEN0 bit = 0x0, the binary rollover is 512 Hz, and the digital rollover is 256 Hz. When the PPSEN0 bit = 0x1, this encoding is reserved.																											
0xA	When the PPSEN0 bit = 0x0, the binary rollover is 1.024 kHz, and the digital rollover is 512 Hz. When the PPSEN0 bit = 0x1, this encoding is reserved.																											
0xB	When the PPSEN0 bit = 0x0, the binary rollover is 2.048 kHz, and the digital rollover is 1.024 kHz. When the PPSEN0 bit = 0x1, this encoding is reserved.																											
0xC	When the PPSEN0 bit = 0x0, the binary rollover is 4.096 kHz, and the digital rollover is 2.048 kHz. When the PPSEN0 bit = 0x1, this encoding is reserved.																											
0xD	When the PPSEN0 bit = 0x0, the binary rollover is 8.192 kHz, and the digital rollover is 4.096 kHz. When the PPSEN0 bit = 0x1, this encoding is reserved.																											
0xE	When the PPSEN0 bit = 0x0, the binary rollover is 16.384 kHz, and the digital rollover is 8.092 kHz. When the PPSEN0 bit = 0x1, this encoding is reserved.																											
0xF	When the PPSEN0 bit = 0x0, the binary rollover is 32.768 kHz, and the digital rollover is 16.384 kHz. When the PPSEN0 bit = 0x1, this encoding is reserved.																											
<p>Note that in the binary rollover mode, the EN0PPS signal has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the EN0PPS signal frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: When PPSCTRL = 0x1, EN0PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms. When PPSCTRL = 0x2, EN0PPS (2 Hz) is a sequence of:</p> <ul style="list-style-type: none"> ■ One clock of 50 percent duty cycle and 537 ms period ■ Second clock of 463 ms period (268 ms low and 195 ms high) 																												

Bit/Field	Name	Type	Reset	Description
				<p>When PPSCTRL = 0x3, EN0PPS (4 Hz) is a sequence of:</p> <ul style="list-style-type: none">■ Three clocks of 50 percent duty cycle and 268 ms period■ Fourth clock of 195 ms period (134 ms low and 61 ms high) <p>This signaling behavior is because of the non-linear toggling of bits in the digital rollover mode in the Ethernet MAC System Time - Nanoseconds (EMACTIMNANO) register.</p>

Register 50: Ethernet MAC PPS0 Interval (EMACPPS0INTVL), offset 0x760

The **MAC PPS0 Interval (EMACPPS0INTVL)** register contains the number of units of sub-second increment value between the rising edges of EN0PPS signal output.

Note: The PTP reference clock referred to below is MOSC clock in coarse update mode and in fine correction mode, is the clock tick at which the system time gets updated.

Ethernet MAC PPS0 Interval (EMACPPS0INTVL)

Base 0x400E.C000
Offset 0x760
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	PPS0INT	RW	0x0	<p>PPS0 Output Signal Interval</p> <p>These bits store the interval between the rising edges of the EN0PPS signal output in terms of units of sub-second increment value.</p> <p>It must be programmed one value less than the required interval. For example, if the PTP reference clock is 25 MHz (period of 40 ns), and desired interval between rising edges of EN0PPS signal output is 120 ns (that is, three units of sub-second increment value), then you should program value 2 (3 -1) in this register.</p>

Register 51: Ethernet MAC PPS0 Width (EMACPPS0WIDTH), offset 0x764

The **MAC PPS0 Width (EMACPPS0WIDTH)** register contains the number of units of sub-second increment value between the rising and corresponding falling edges of the EN0PPS output signal.

Note: The PTP reference clock referred to below is MOSC clock in coarse update mode and in fine correction mode, is the clock tick at which the system time gets updated.

Ethernet MAC PPS0 Width (EMACPPS0WIDTH)

Base 0x400E.C000
Offset 0x764
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	PPS0WIDTH	RW	0x0	EN0PPS Output Signal Width These bits store the width between the rising edges and corresponding falling edge of the EN0PPS signal output in terms of units of sub-second increment value. It must be programmed one value less than the required interval. For example, if the PTP reference clock is 25 MHz (period of 40 ns), and the desired interval between rising edges of EN0PPS signal output is 80 ns (that is, two units of sub-second increment value), then you should program value 1 (2 -1) in this register.
				Note: The value programmed in this register must be less than the value programmed in the Ethernet MAC PPS0 Interval (EMACPPS0INTVL) register, offset 0x760.

Register 52: Ethernet MAC DMA Bus Mode (EMACDMABUSMOD), offset 0xC00

The **Ethernet MAC DMA Bus Mode (EMACDMABUSMODE)** register establishes the operation modes for the DMA.

Ethernet MAC DMA Bus Mode (EMACDMABUSMOD)

Value	Description									
0	Reset is completed. A value of 0 should be read before reprogramming any MAC registers after a reset									
1	MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the MAC clock domains.									

Register 53: Ethernet MAC Transmit Poll Demand (EMACTXPOLLD), offset 0xC04

The **MAC Transmit Poll Demand (EMACTXPOLLD)** register enables the TX DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the TX DMA if it is in the suspend mode. The TX DMA can go into the SUSPEND mode because of an underflow error in a transmitted frame or the unavailability of descriptors owned by it. This Transmit Poll Demand command can be given at any time and the TX DMA resets this command when it again starts fetching the current descriptor from host memory.

Ethernet MAC Transmit Poll Demand (EMACTXPOLLD)

Base 0x400E.C000

Offset 0xC04

Type WO, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0	TPD	WO	0x0	Transmit Poll Demand
------	-----	----	-----	----------------------

When these bits are written with any value, the DMA reads the current descriptor pointed to by the **MAC Current Host Transmit Descriptor (EMACHOSTXDESC)** register. If that descriptor is not available (owned by the Host), the transmission returns to the SUSPEND state and the TU bit of the **EMACDMARIS** is asserted. If the descriptor is available, the transmission resumes.

Register 54: Ethernet MAC Receive Poll Demand (EMACRXPOLLD), offset 0xC08

The **Ethernet MAC Receive Poll Demand (EMACRXPOLLD)** register enables the RX DMA to check for new descriptors. This command is used to wake up the RX DMA from the SUSPEND state. The RX DMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Ethernet MAC Receive Poll Demand (EMACRXPOLLD)

Base 0x400E.C000

Bit/Field Name Type Reset Description

31:0 RPD WO 0x0 Receive Poll Demand

When these bits are written with any value, the DMA reads the current descriptor pointed to by **MAC Current Host Receive Descriptor (EMACHOSRXDESC)** register. If that descriptor is not available (owned by the Host), the reception returns to the SUSPEND state and the **RU** bit of **EMACDMARIS** is not asserted. If the descriptor is available, the RX DMA returns to the active state.

Register 55: Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR), offset 0xC0C

The **Ethernet MAC Receive Descriptor List Address (EMACRXDLADDR)** register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be word-aligned. The DMA internally converts it to a 32-bit aligned address by making the two least significant bits zero. Writing to this register is permitted only when the DMA receive transaction has stopped (**SR** = 0 in the **MAC DMA Operation Mode (EMACDMAOPMODE)** register). When stopped, this register must be written with a new descriptor list address before the receive Start command is given. When you set the **SR** bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the **SR** bit is set to 0, then the DMA uses the already existing descriptor address.

31:2	STRXLIST	RW	0x0	Start of Receive List This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits[1:0] are ignored and internally taken as zero by the DMA. Therefore, bits[1:0] are read-only (RO).
1:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 56: Ethernet MAC Transmit Descriptor List Address (EMACTXDLADDR), offset 0xC10

The **MAC Transmit Descriptor List Address (EMACTXDLADDR)** register points to the start of the transmit descriptor list. The descriptor lists reside in the host's physical memory space and must be word-aligned.

This register can only be written when the DMA transmit has stopped (ST = 0 in the **MAC DMA Operation Mode (EMACDMAOPMODE)** register). When the ST bit is set, the DMA takes the uses the newly programmed descriptor base address.

If this register is not changed when the ST bit is set to 0, then the DMA uses the already existing descriptor address.

Ethernet MAC Transmit Descriptor List Address (EMACTXDLADDR)

Base 0x400E.C000

Offset 0xC10

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	TXDLADDR	RW	0x0	Start of Transmit List Base Address This field contains the base address of the first descriptor in the transmit descriptor list. The LSB bits (1:0) for 32-bit bus width are ignored and are internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).
1:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 57: Ethernet MAC DMA Interrupt Status (EMACDMARIS), offset 0xC14

The **MAC DMA Interrupt Status (EMACDMARIS)** register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing a 1 to any bit in the lower half-word of this register clears the bit and writing a 0 has no effect. Status bits [16:0] can be masked by enabling the appropriate mask in the **MAC DMA Interrupt Mask Register (EMACDMAIM)** register.

Register 60: Ethernet MAC Missed Frame and Buffer Overflow Counter (EMACMFBOC), offset 0xC20

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counters. The counter is used for diagnostic purposes. The MISFRMCNT field indicates missed frames because of the host buffer being unavailable. The OVFFRMCNT field indicates missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Ethernet MAC Missed Frame and Buffer Overflow Counter (EMACMFBOC)

Base 0x400E.C000

Offset 0xC20

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:29	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
28	OVFCNTOVF	RO	0	Overflow Bit for FIFO Overflow Counter This bit is set every time the overflow frame counter (bits [27:17]) overflows; that is, the RX FIFO overflows with the overflow frame counter at maximum value. In such a scenario, the overflow frame counter is reset to all zeros and this bit indicates the rollover happened.
27:17	OVFFRMCNT	RO	0x0	Overflow Frame Counter This field indicates the number of frames missed by the application. This counter is incremented each time the TX/RX Controller indicates overflow. This counter is cleared when the TX/RX Controller accepts data.
16	MISFRMCNT	RO	0x0	Overflow bit for Missed Frame Counter This bit is set every time the Missed Frame Counter (bits [15:0]) overflows; which means the DMA discards an incoming frame because of the Host Receive Buffer being unavailable with the missed frame counter at maximum value. In such a scenario, the Missed Frame Counter is reset to all zeros and this bit indicates that the rollover happened.
15:0	MISFRMCNT	RO	0x0	Missed Frame Counter This field indicates the number of frames missed by the controller because of the Host Receive Buffer being unavailable. This counter is incremented each time the DMA discards an incoming frame. This counter is cleared when the DMA accepts frames.

Register 61: Ethernet MAC Receive Interrupt Watchdog Timer (EMACRXINTWDT), offset 0xC24

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt, RI (Bit 6), of the **EMACDMARIS** register at EMAC offset 0xC14.

Ethernet MAC Receive Interrupt Watchdog Timer (EMACRXINTWDT)

Base 0x400E.C000

Offset 0xC24

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	RIWT	RW	0x0	<p>Receive Interrupt Watchdog Timer Count</p> <p>This field indicates the period in which the receive counter expires. The value in this field is programmed by 256 to calculate the number of system clock periods the timer must count.</p> <p>Watchdog Timer Period = (RIWT * 256) system clocks.</p> <p>When the watchdog timer runs out, the RI bit is set and the timer is stopped.</p> <p>If the RDES[31] bit is clear, the watchdog timer is reset.</p>

Register 62: Ethernet MAC Current Host Transmit Descriptor (EMACHOSTXDESC), offset 0xC48

The **MAC Current Host Transmit Descriptor (EMACHOSTXDESC)** register points to the start address of the current Transmit Descriptor read by the DMA.

Ethernet MAC Current Host Transmit Descriptor (EMACHOSTXDESC)

Base 0x400E.C000

Offset 0xC48

Type R, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	CURTXDESC	RO	0x0	Host Transmit Descriptor Address Pointer This register contains the start address of the current transmit descriptor read by the DMA. This register is cleared on reset. The pointer is updated by the DMA during operation.

Register 63: Ethernet MAC Current Host Receive Descriptor (EMACHOSRXDESC), offset 0xC4C

The **MAC Current Host Receive Descriptor (EMACHOSRXDESC)** register points to the start address of the current Receive Descriptor read by the DMA.

Ethernet MAC Current Host Receive Descriptor (EMACHOSRXDESC)

Base 0x400E.C000

Offset 0xC4C

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	CURRXDESC	RO	0x0	Host Receive Descriptor Address Pointer This register contains the start address of the current receive descriptor read by the DMA. This register is cleared on reset. The pointer is updated by the DMA during operation.

Register 64: Ethernet MAC Current Host Transmit Buffer Address (EMACHOSTXBA), offset 0xC50

The **MAC Current Host Transmit Buffer Address (EMACHOSTXBA)** register points to the current Transmit Buffer Address being read by the DMA.

Ethernet MAC Current Host Transmit Buffer Address (EMACHOSTXBA)

Base 0x400E.C000

Offset 0xC50

Type R, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	CURTXBUFA	RO	0x0	<p>Host Transmit Buffer Address Pointer</p> <p>This register contains the current transmit buffer address being read by the DMA.</p> <p>This register is cleared on reset. The pointer is updated by the DMA during operation.</p>

Register 65: Ethernet MAC Current Host Receive Buffer Address (EMACHOSRXBA), offset 0xC54

The **MAC Current Host Receive Buffer Address (EMACHOSRXBA)** register points to the current receive buffer address being read by the DMA.

Ethernet MAC Current Host Receive Buffer Address (EMACHOSRXBA)

Base 0x400E.C000

Offset 0xC54

Type R, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	CURRXBUFA	RO	0x0	<p>Host Receive Buffer Address Pointer</p> <p>This register contains the current receive buffer address being read by the DMA.</p> <p>This register is cleared on reset. The pointer is updated by the DMA during operation.</p>

Register 66: Ethernet MAC Peripheral Property Register (EMACPP), offset 0xFC0

This register defines the Ethernet MAC and PHY type used.

Ethernet MAC Peripheral Property Register (EMACPP)

Base 0x400E.C000
Offset 0xFC0
Type RO, reset 0x0000.0103

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10:8	MACTYPE	RO	0x1	Ethernet MAC Type
		Value		Description
		0x0		Stellaris® LM3S-class MAC.
		0x1		Tiva™ TM4C129x-class MAC.
		0x2-0x7		Reserved
7:3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	PHYTYPE	RO	0x3	Ethernet PHY Type
				This field specifies the type of PHY provided.
		Value		Description
		0x0		No PHY
		0x1		Fury class PHY
		0x2		Tempest/Firestorm class PHY
		0x3		Snowflake class PHY
		0x4-0x7		Reserved

Register 67: Ethernet MAC Peripheral Configuration Register (EMACPC), offset 0xFC4

The **Ethernet MAC Peripheral Configuration Register (EMACPC)** register configures the MAC and PHY reset and interface parameters.

Ethernet MAC Peripheral Configuration Register (EMACPC)

Base 0x400E.C000

Offset 0xFC4

Type RW, reset 0x0080.040E

16	CLKEN	RW	0	<p>ENORREF_CLK Signal Enable</p> <p>Note that when using the RMII interface, this bit must be set to a 1.</p> <table> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>ENORREF_CLK signal is disabled</td> </tr> <tr> <td>1</td> <td>ENORREF_CLK signal is enabled</td> </tr> </tbody> </table>	Value	Description	0	ENORREF_CLK signal is disabled	1	ENORREF_CLK signal is enabled
Value	Description									
0	ENORREF_CLK signal is disabled									
1	ENORREF_CLK signal is enabled									
15:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						

Register 69: Ethernet PHY Raw Interrupt Status (EPHYRIS), offset 0xFD0

The **Ethernet PHY Raw Interrupt Status (EPHYRIS)** register is used to mask the interrupt from the Ethernet PHY, which is either from the internal integrated PHY or an external PHY.

Ethernet PHY Raw Interrupt Status (EPHYRIS)

Base 0x400E.C000
Offset 0xFD0
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	INT	RO	0	Ethernet PHY Raw Interrupt Status
		Value	Description	
		0	No interrupt has triggered.	
		1	The Ethernet PHY has signaled an interrupt using the EN0INTR input.	

Register 70: Ethernet PHY Interrupt Mask (EPHYIM), offset 0xFD4

The **Ethernet PHY Interrupt Mask (EPHYIM)** register is used to mask the interrupt from the Ethernet PHY, which is either from the internal integrated PHY or an external PHY.

Ethernet PHY Interrupt Mask (EPHYIM)

Base 0x400E.C000
Offset 0xFD4
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	INT	RW	0	Ethernet PHY Interrupt Mask
Value Description				
0 An Ethernet PHY interrupt is suppressed and not sent to the interrupt controller. 1 An Ethernet PHY interrupt is sent to the interrupt controller when the INT bit is set in the EPHYRIS register. This interrupt could be generated from either the integrated PHY or an external PHY through the EN0INTR signal depending on the configuration chosen.				

Register 71: Ethernet PHY Masked Interrupt Status and Clear (EPHYMISC), offset 0xFD8

The **Ethernet Masked Interrupt Status and Clear (EPHYMISC)** register displays the masked interrupt status of the Ethernet PHY, which is either from the internal integrated PHY or an external PHY. This register can be written to clear the **EPHYRIS** register.

This register is used for clearing the **EPHYRIS** register bits.

Ethernet PHY Masked Interrupt Status and Clear (EPHYMISC)

Base 0x400E.C000
Offset 0xFD8
Type RW1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	INT	RW1C	0	Ethernet PHY Status and Clear register Reading this register provides a result which is the logical AND of the EPHYRIS and EPHYIM registers. A write of 1 to a bit of this register clears the corresponding bit in the EPHYRIS register.

Note: The Ethernet MAC interrupt is an OR'd summary of both the masked **EMACRIS** register output and this register. When an Ethernet MAC interrupt is asserted, software must check both the **EMACRIS** and **EMACIM** registers along with this register.

24.8 Ethernet PHY Register Descriptions

This section lists and describes the PHY registers, in numerical order by address. Also see “Ethernet MAC Register Descriptions” on page 1659.

Register 72: Ethernet PHY Basic Mode Control - MR0 (EPHYBMCR), address 0x000

This register describes the basic mode controls available to the EPHY. The reset state of the ANEN bit is controlled by the EMACPC register.

Ethernet PHY Basic Mode Control - MR0 (EPHYBMCR)

Base n/a
Address 0x000
Type RW, reset 0x3100

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	RW	RO														
Reset	0	0	1	1	0	0	0	1	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
15	MIIRESET	RW	0	MII Register reset Writing a 1 to this bit resets the contents of the MII-related registers, EPHYBMCR (0x000) EPHYANA (0x004) and EPHYANNPTR (0x007) registers . When the reset operation is done, this bit is cleared to 0 automatically. Value Description 0 Normal operation. 1 Initiate MII Reset / Reset in Process.
14	MILOOPBK	RW	0	MII Loopback When MII loopback mode is activated, the transmitter data presented on MII TXD is looped back to MII RXD internally. Value Description 0 Normal operation. 1 MII Loopback enabled.
13	SPEED	RW	1	Speed Select When auto-negotiation is disabled writing to this bit allows the port speed to be selected. Value Description 0 10Mbs 1 100Mbs
12	ANEN	RW	1	Auto-Negotiate Enable Value Description 0 Auto-Negotiation Disabled – the SPEED bit and the DUPLEXM bit determine the port speed and duplex mode. 1 Auto-Negotiation Enabled – the SPEED bit and the DUPLEXM bit of this register are ignored when this bit is set.

Bit/Field	Name	Type	Reset	Description						
11	PWRDWN	RW	0	<p>Power Down</p> <p>Setting this bit powers down the PHY. 14	100BTXFD	RO	1	100Base-TX Full Duplex Capable
		Value	Description	
		0	Device does not support 100Base-TX in full duplex mode.	
		1	Device supports 100Base-TX in full duplex mode.	
13	100BTXHD	RO	1	100Base-TX Half Duplex Capable
		Value	Description	
		0	The device does not support 100Base-TX in half duplex mode.	
		1	The device supports 100Base-TX in half duplex mode.	
12	10BTFD	RO	1	10 Base-T Full Duplex Capable
		Value	Description	
		0	The device does not support 10Base-T in full duplex mode.	
		1	Device able to perform 10Base-T in full duplex mode.	
11	10BTHD	RO	1	10 Base-T Half Duplex Capable
		Value	Description	
		0	Device not able to perform 10Base-T in half duplex mode.	
		1	Device able to perform 10Base-T in half duplex mode.	
10:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
6	MFPRESUP	RO	1	Preamble Suppression Capable Value Description 0 The device does not perform management transactions with preambles suppressed. 1 The device performs management transactions with preambles suppressed. For this mode, the 32-bits of preamble are needed only once after reset, invalid opcode or invalid turnaround.
5	ANC	RO	0	Auto-Negotiation Complete Value Description 0 Auto-Negotiation process not complete (either still in process, disabled, or reset) 1 Auto-Negotiation process complete.
4	RFAULT	RO	0	Remote Fault Value Description 0 No remote fault condition detected. 1 Remote Fault condition detected (cleared on read or by reset). Fault criteria: Far End Fault Indication or notification from Link Partner of Remote Fault.
3	ANEN	RO	1	Auto Negotiation Enabled Value Description 0 Device is not able to perform Auto-Negotiation. 1 Device is able to perform Auto-Negotiation.
2	LINKSTAT	RO	0	Link Status Value Description 0 Link not established. 1 Valid link established (for either 10 or 100Mbs operation).
1	JABBER	RO	0	Jabber Detect This bit is implemented with a latching function, such that the occurrence of a jabber condition causes it to set until it is cleared by a read from this register, by the management interface, or by a reset. Value Description 0 No Jabber condition detected. 1 Jabber condition detected

Bit/Field	Name	Type	Reset	Description
0	EXTEN	RO	1	Extended Capability Enable
Value Description				
0				Basic register set capabilities only.
1				Extended register capabilities.

Register 74: Ethernet PHY Identifier Register 1 - MR2 (EPHYID1), address 0x002

The **Ethernet PHY Identifier 1 and 2 (EPHYIDn)** registers together form a unique identifier. The identifier consists of a concatenation of the Organizationally Unique Identifier (OUI), the vendor's model number and the model revision number. A PHY may return a value of zero in each of the 32 bits of the PHY Identifier if desired. The PHY Identifier is intended to support network management. The Texas Instruments IEEE-assigned OUI is 0x080028. This OUI field is broken into two fields in the **EPHYID1** and **EPHYID2** register. The most significant OUI field, **OUIMSB** in the **EPHYID1** register, is equal to 0x0002 (the two most significant bits of the OUI are ignored). The least significant OUI field, **OUILSB** in the **EPHYID2** register, is equal to 0x28.

Ethernet PHY Identifier Register 1 - MR2 (EPHYID1)

Base n/a

Address 0x002

Type R, reset 0x2000

Bit/Field	Name	Type	Reset	Description
15:0	OUIMSB	RO	0x2000	OUI Most Significant Bits OUI[21:6] = 0x200. The most significant two bits of the OUI are ignored (the IEEE standard refers to these as bits 1 and 2).

Register 75: Ethernet PHY Identifier Register 2 - MR3 (EPHYID2), address 0x003

The **Ethernet PHY Identifier 1 and 2 (EPHYIDn)** registers together form a unique identifier. The identifier consists of a concatenation of the Organizationally Unique Identifier (OUI), the vendor's model number and the model revision number. A PHY may return a value of zero in each of the 32 bits of the PHY Identifier if desired. The PHY Identifier is intended to support network management. The Texas Instruments IEEE-assigned OUI is 0x080028. This OUI field is broken into two fields in the **EPHYID1** and **EPHYID2** register. The most significant OUI field, OUIMSB in the **EPHYID1** register, is equal to 0x0002 (the two most significant bits of the OUI are ignored). The least significant OUI field, OUILSB in the **EPHYID2** register, is equal to 0x28.

Ethernet PHY Identifier Register 2 - MR3 (EPHYID2)

Base n/a

Address 0x003

Type R, reset 0xA221

Bit/Field	Name	Type	Reset	Description
15:10	OUILSB	RO	0x28	OUI Least Significant Bits Bits 19 to 24 of the OUI (0x080028) are mapped from bits 15 to 10 of this register respectively.
9:4	VNDRMDL	RO	0x22	Vendor Model Number The six bits of vendor model number are mapped from bits 9 to 4 (most significant bit to bit 9).
3:0	MDLREV	RO	0x1	Model Revision Number Four bits of the vendor model revision number are mapped from bits 3 to 0 (most significant bit to bit 3). This field is incremented for all major device changes.

Register 76: Ethernet PHY Auto-Negotiation Advertisement - MR4 (EPHYANA), address 0x004

This register contains the advertised abilities of this device as they are transmitted to its link partner during Auto-Negotiation.

Bit/Field	Name	Type	Reset	Description
4:0	FLDWNM	RW	0x0	<p>Fast Link Down Modes</p> <p>The Fast Link Down function is an OR of the following five options. The application can enable combinations of these conditions.</p> <p>Bit 4: Drop the link due to descrambler sync loss. If this bit is enabled, the link is dropped when the receiver loses synchronization of the transmitter.</p> <p>Bit 3: Drop the link based on RX Error count of the MII interface. When a predefined number of 32 RX Error occurrences in a 10µs interval is reached, the link is dropped.</p> <p>Bit 2: Drop the link based on MLT3 Errors count (Violation of the MLT3 coding in the DSP output). When a predefined number of 20 MLT3 Error occurrences in a 10µs interval is reached, the link is dropped.</p> <p>Bit 1: Drop the link based on Low SNR Threshold. When a predefined number of 20 Threshold crossing occurrences in a 10µs interval is reached, the link is dropped.</p> <p>Bit 0: Drop the link based on Signal/Energy loss indication – When the Energy detector indicates Energy Loss, the link is dropped. Typical reaction time is 10µs.</p>

Register 84: Ethernet PHY Register Control - MR13 (EPHYREGCTL), address 0x00D

EPHYREGCTL (0x00D) and **EPHYADDR** (0x00E) registers allow read/write access to the extended register set using indirect addressing. The modes for the **FUNC** field are as follows:

- **EPHYREGCTL[15:14]** = 0x0: A write to **EPHYADDR** modifies the extended register set address register. This address register must be initialized in order to access any of the registers within the extended register set.
- **EPHYREGCTL[15:14]** = 0x1: A read/write to **EPHYADDR** operates on the register within the extended register set selected (pointed to) by the value in the address register. The address register contents (pointer) remain unchanged.
- **EPHYREGCTL[15:14]** = 0x2: A read/write to **EPHYADDR** operates on the register within the extended register set selected (pointed to) by the value in the address register. After that access is complete, for both reads and writes, the value in the address register is incremented.
- **EPHYREGCTL[15:14]** = 0x3: A read/write to **EPHYADDR** operates on the register within the extended register set selected (pointed to) by the value in the address register. After that access is complete, for write accesses only, the value in the address register is incremented. For read accesses, the value of the address register remains unchanged.

This register is the MDIO Manageable Device (MMD) access control. In general, register **EPHYREGCTL [4:0]** is the device address, DEVAD, that directs any accesses of **EPHYADDR** (0x00E) register to the appropriate MMD. It also contains selection bits for auto-increment of the data register. This register contains the device address to be written to access the extended registers. Write 0x1F into bits [4:0] of this register. It also contains selection bits [15:14] for the address auto-increment mode of **EPHYADDR**.

Bit/Field	Name	Type	Reset	Description
15:14	FUNC	WO	0	Function Value Description 0x0 Address 0x1 Data, no post increment 0x2 Data, post increment on read and write 0x3 Data, post increment on write only
13:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
4:0	DEVAD	WO	0x0	<p>Device Address</p> <p>In general, these bits [4:0] are the device address DEVAD that directs any accesses of EPHYADDR register (0x00E) to the appropriate MMD. The PHY uses the vendor specific DEVAD [4 : 0] = 0x1F for accesses. All accesses through registers EPHYREGCR and EPHYADDR should use this DEVAD. Transactions with other DEVAD are ignored.</p>

Register 85: Ethernet PHY Address or Data - MR14 (EPHYADDR), address 0x00E

This register is the address/data MMD register. It is used in conjunction with **EPHYREGCTL** register (PHY offset 0x00D) to provide the access by an indirect read/write mechanism to the extended register set.

Ethernet PHY Address or Data - MR14 (EPHYADDR)

Base n/a

Address 0x00E

Type WO, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:0	ADDRDATA	WO	0x0000	Address or Data If the EPHYREGCTL register bits [15:14] = 0x0, this register holds the MDIO Manageable Device (MMD) DEVAD's address register, otherwise holds the MMD DEVAD's data register. See EPHYREGCTL register for more information about DEVAD field.

Register 86: Ethernet PHY Status - MR16 (EPHYSTS), address 0x010

This register provides quick access to commonly accessed PHY control status and general information.

Ethernet PHY Status - MR16 (EPHYSTS)

Base n/a
Address 0x010

Register 88: Ethernet PHY MII Interrupt Status 1 - MR18 (EPHYMISR1), address 0x012

This register contains events status and enables for the interrupt function. If an event has occurred since the last read of this register, the corresponding status bit is set. If the corresponding enable bit in the register is set, an interrupt is generated if the event occurs. The INTEN bit (Bit 1) in the **EPHYSR** register (0x011) must also be set to allow interrupts. The status indications in this register are set even if the interrupt is not enabled.

Bit/Field	Name	Type	Reset	Description
3	MDICOEN	RW	0	MDI/MDIX Crossover Status Changed Interrupt Enable Value Description 0 MDI/MDIX Crossover Change Status interrupt disabled. 1 MDI/MDIX Crossover Change Status interrupt enabled.
2	SLEEPEN	RW	0	Sleep Mode Event Interrupt Enable Value Description 0 Sleep mode interrupt disabled. 1 Sleep Mode event interrupt enabled.
1	POLINTEN	RW	0	Polarity Changed Interrupt Enable Value Description 0 Polarity Change interrupt is disabled. 1 Polarity change interrupt is enabled.
0	JABBEREN	RO	0	Jabber Detect Event Interrupt Enable Value Description 0 Jabber detect interrupt disabled. 1 Jabber detect interrupt enabled.

Register 90: Ethernet PHY False Carrier Sense Counter - MR20 (EPHYFCSCR), address 0x014

This counter provides information required to implement the False Carriers attribute within the MAU managed object class of Clause 30 of the IEEE 802.3u specification.

Ethernet PHY False Carrier Sense Counter - MR20 (EPHYFCSCR)

Base n/a
Address 0x014
Type RO, reset 0x0000

Bit/Field	Name	Type	Reset	Description
15:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	FCSCNT	RO	0x00	<p>False Carrier Event Counter</p> <p>This 8-bit counter increments on every false carrier event. This counter stops when it reaches its maximum count (0xFF). When the counter exceeds half full (0x7F), an interrupt event is generated. This register is cleared on read.</p>

Register 91: Ethernet PHY Receive Error Count - MR21 (EPHYRXERCNT), address 0x015

This counter provides information required to implement the Symbol Error During Carrier attribute within the PHY managed object class of Clause 30 of the IEEE 802.3u specification.

Ethernet PHY Receive Error Count - MR21 (EPHYRXERCNT)

Base n/a

Address 0x015

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
15:0	RXERRCNT	RO	0x0	Receive Error Count When a valid carrier is present (while EN0RXDV is active), and there is at least one occurrence of an invalid data symbol, this 16-bit counter increments for each receive error detected. The EPHYRXERCNT counter does not count in MII loopback mode. The counter stops when it reaches its maximum count of 0xFFFF. When the counter exceeds half-full (0x7FFF), an interrupt is generated. This register is cleared on read.

Register 92: Ethernet PHY BIST Control - MR22 (EPHYBISTCR), address 0x016

This register is used for Build-In Self Test (BIST) configuration. The BIST functionality provides Pseudo Random Bit Stream (PRBS) mechanism including packet generation generator and checker. Selection of the exact loopback point in the signal chain is also done in this register.

Ethernet PHY BIST Control - MR22 (EPHYBISTCR)

Base n/a
Address 0x016
Type RW, reset 0x0100

Bit/Field	Name	Type	Reset	Description						
15	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

25 Universal Serial Bus (USB) Controller

Important: The full USB chapter is under NDA. This chapter describes the module features at a high level. For a copy of the full NDA data sheet, follow the instructions in the *Non-Disclosure Agreement for the Tiva C Series TM4C129XKCZAD Microcontroller Data Sheet* (literature number [SPMS425](#)).

The TM4C129XKCZAD USB controller operates as a full-speed or low-speed function controller during point-to-point communications with USB Host, Device, or OTG functions. If the integrated ULPI interface is utilized, the USB can operate at high-speed. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. 16 endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus 14 endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing. USB DMA access to the FIFO allows minimal interference from system software. Software-controlled connect and disconnect allows flexibility during USB device start-up. The controller complies with OTG Standard's Session Request Protocol (SRP) and Host Negotiation Protocol (HNP).

The TM4C129XKCZAD USB module has the following features:

- Complies with USB-IF (Implementer's Forum) certification standards
- USB 2.0 high-speed (480 Mbps) operation with the integrated ULPI interface communicating with an external PHY
- Link Power Management support which uses link-state awareness to reduce power usage
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
 - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
 - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop detection and interrupt
- Integrated USB DMA with bus master capability
 - Up to eight RX Endpoint channels and up to eight TX Endpoint channels are available.
 - Each channel can be separately programmed to operate in different modes
 - Incremental burst transfers of 4-, 8-, 16- or unspecified length supported

25.1 Block Diagram

Figure 25-1. USB Module Block Diagram

25.2 Signal Description

The following table lists the external signals of the USB controller and describes the function of each. Some USB controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these USB signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the USB function. The number in parentheses is the encoding that must be programmed into the **PMCn** field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the USB signal to the specified GPIO port pin. The **USB0VBUS** and **USB0ID** signals are configured by clearing the appropriate **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Note: When used in OTG mode, **USB0VBUS** and **USB0ID** do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the **DEVMOD** field in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the **USB0VBUS** and/or **USB0ID** inputs to fixed levels internally, freeing the **PB0** and **PB1** pins for GPIO use. Note that **PB1 (USB0VBUS)** is a 5-V tolerant signal as required. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

The termination resistors for the USB PHY have been added internally, and thus there is no need for external resistors. For a device, there is a 1.5 KOhm pull-up on the D+ and for a host there are 15 KOhm pull-downs on both D+ and D-.

Note: Port pins PL6 and PL7 operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 769 and “Recommended GPIO Operating Characteristics” on page 2101 for more information.

Table 25-1. USB Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
USB0CLK	B17	PB3 (14)	O	TTL	60-MHz clock to the external PHY.
USB0D0	G16	PL0 (14)	I/O	TTL	USB data 0.
USB0D1	H19	PL1 (14)	I/O	TTL	USB data 1.
USB0D2	G18	PL2 (14)	I/O	TTL	USB data 2.
USB0D3	J18	PL3 (14)	I/O	TTL	USB data 3.
USB0D4	H18	PL4 (14)	I/O	TTL	USB data 4.
USB0D5	G19	PL5 (14)	I/O	TTL	USB data 5.
USB0D6	B12	PP5 (14)	I/O	TTL	USB data 6.
USB0D7	D8	PP4 (14)	I/O	TTL	USB data 7.
USB0DIR	C12	PP3 (14)	O	TTL	Indicates that the external PHY is able to accept data from the USB controller.
USB0DM	B18	PL7	I/O	Analog	Bidirectional differential data pin (D- per USB specification) for USB0.
USB0DP	C18	PL6	I/O	Analog	Bidirectional differential data pin (D+ per USB specification) for USB0.
USBOEPEN	V5 R7 B3	PA6 (5) PA7 (11) PD6 (5)	O	TTL	Optionally used in Host mode to control an external power source to supply power to the USB bus.
USB0ID	A16	PB0	I	Analog	This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side).
USB0NXT	B13	PP2 (14)	O	TTL	Asserted by the external PHY to throttle all data types.
USB0PFLT	R7 B2	PA7 (5) PD7 (5)	I	TTL	Optionally used in Host mode by an external power source to indicate an error state by that power source.
USB0STP	A17	PB2 (14)	O	TTL	Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.
USB0VBUS	B16	PB1	I/O	Analog	This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.

25.3 Register Map

Table 25-2 on page 1839 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 409). There must be a delay of 3 system clocks after the USB module clock is enabled before any USB module registers are accessed.

Note: Descriptions for all these registers can be found in the NDA version of the data sheet.

Table 25-2. List of Registers

Offset	Name	Description
0x000	USBFADDR	USB Device Functional Address
0x001	USBPOWER	USB Power
0x002	USBTXIS	USB Transmit Interrupt Status
0x004	USBRXIS	USB Receive Interrupt Status
0x006	USBTXIE	USB Transmit Interrupt Enable
0x008	USBRXIE	USB Receive Interrupt Enable
0x00A	USBIS	USB General Interrupt Status
0x00B	USBIE	USB Interrupt Enable
0x00C	USBFRAME	USB Frame Value
0x00E	USBEPIDX	USB Endpoint Index
0x00F	USBTEST	USB Test Mode

26 LCD Controller

The Liquid Crystal Display (LCD) Controller provides support for a variety of LCD and OLED panels.

The TM4C129XKCZAD controller includes an LCD Controller with the following features:

- Character-based panels
 - Support for two character panels (CS0 and CS1) with independent and programmable bus timing parameters when in asynchronous Hitachi, Motorola, and Intel modes
 - Support for one character panel (CS0) with programmable bus timing parameters when in synchronous Motorola and Intel modes
 - Can be used as a generic 16-bit address/data interleaved MPU bus master with no external stall
- Passive matrix LCD panels
 - Panel types including STN, DSTN, and C-DSTN
 - AC Bias Control
- Active matrix LCD panels
 - Panel types including TN TFT
 - 1, 2, 4, or 8 bits per pixel with palette RAM and 16 or 24 bits per pixel without palette RAM
- OLED Panels
 - Passive Matrix (PM OLED) with frame buffer and controller IC inside the panel
 - Active Matrix (AM OLED)
- Bus mastering capability from either system SRAM or EPI memory.

26.1 Block Diagram

The LCD controller consists of two independent controllers, the Raster Controller and the LCD Interface Display Driver (LIDD) controller. Each controller operates independently from the other and only one of them is active at any given time.

- The Raster Controller handles the synchronous LCD interface. It provides timing and data for constant graphics refresh to a passive display. It supports a wide variety of monochrome and full-color display types and sizes by use of programmable timing controls, a built-in palette, and a gray-scale/serializer. Graphics data is processed and stored in frame buffers. A frame buffer is a contiguous memory block in the system. A built-in DMA engine supplies the graphics data to the Raster engine which, in turn, outputs to the external LCD device.
- The LIDD Controller supports the asynchronous LCD interface. It provides full-timing programmability of control signals (chip selects, read/write strobes, enable, direction) and output data.

Figure 26-1 on page 1846 shows the LCD controller details. The raster and LIDD Controllers are responsible for generating the correct external timing. The DMA engine provides a constant flow of data from the frame buffer(s) to the external LCD panel via the Raster and LIDD Controllers. In addition, CPU access is provided to read and write registers.

The solid, thick lines in Figure 13-1 indicate the data path. For more information on the Raster Controller data path, see Figure 26-2 on page 1853 .

Figure 26-1. LCD Block Diagram

26.2 Signal Description

The following table lists the external signals of the LCD controller and describes the function of each.

Table 26-1. LCD Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
LCDAC	N1	PJ6 (15)	O	TTL	LCD AC bias or latch enable in Raster mode; Primary chip select (CS0)/Primary Enable (E0) in LIDD MPU/Hitachi mode
LCDCP	N5	PR0 (15)	O	TTL	LCD Pixel Clock in Raster mode; read strobe or read/write strobe in LIDD mode
LCDDATA00	P3	PR4 (15)	I/O	TTL	LCD Data Pin 0 input/output.
LCDDATA01	P2	PR5 (15)	I/O	TTL	LCD Data Pin 1 input/output.
LCDDATA02	U8	PF7 (15)	I/O	TTL	LCD Data Pin 2 input/output.
LCDDATA03	V8	PR3 (15)	I/O	TTL	LCD Data Pin 3 input/output.
LCDDATA04	W9	PR6 (15)	I/O	TTL	LCD Data Pin 4 input/output.
LCDDATA05	R10	PR7 (15)	I/O	TTL	LCD Data Pin 5 input/output.

Table 26-1. LCD Signals (212BGA) (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
LCDDATA06	V9	PS4 (15)	I/O	TTL	LCD Data Pin 6 input/output.
LCDDATA07	T13	PS5 (15)	I/O	TTL	LCD Data Pin 7 input/output.
LCDDATA08	U10	PS6 (15)	I/O	TTL	LCD Data Pin 8 input/output.
LCDDATA09	R13	PS7 (15)	I/O	TTL	LCD Data Pin 9 input/output.
LCDDATA10	W10	PT0 (15)	I/O	TTL	LCD Data Pin 10 input/output.
LCDDATA11	V10	PT1 (15)	I/O	TTL	LCD Data Pin 11 input/output.
LCDDATA12	U12	PN7 (15)	I/O	TTL	LCD Data Pin 12 input/output.
LCDDATA13	T12	PN6 (15)	I/O	TTL	LCD Data Pin 13 input/output.
LCDDATA14	H17	PJ2 (15)	I/O	TTL	LCD Data Pin 14 input/output.
LCDDATA15	F16	PJ3 (15)	I/O	TTL	LCD Data Pin 15 input/output.
LCDDATA16	F18	PJ4 (15)	O	TTL	LCD Data Pin 16 output.
LCDDATA17	E17	PJ5 (15)	O	TTL	LCD Data Pin 17 output.
LCDDATA18	E18	PT2 (15)	O	TTL	LCD Data Pin 18 output.
LCDDATA19	F17	PT3 (15)	O	TTL	LCD Data Pin 19 output.
LCDDATA20	D12	PS0 (15)	O	TTL	LCD Data Pin 20 output.
LCDDATA21	D13	PS1 (15)	O	TTL	LCD Data Pin 21 output.
LCDDATA22	B14	PS2 (15)	O	TTL	LCD Data Pin 22 output.
LCDDATA23	A14	PS3 (15)	O	TTL	LCD Data Pin 23 output.
LCDFP	N4	PR1 (15)	O	TTL	LCD Frame Clock or VSYNC in Raster mode; Address Latch Enable in LIDD mode
LCDLP	N2	PR2 (15)	O	TTL	LCD Line Clock or HSYNC in Raster mode; Write Strobe or Direction bit in LIDD mode
LCDMCLK	T8	PF6 (15)	O	TTL	LCD Memory Clock/Secondary chip Select (CS1)/Secondary Enable (E1) in LIDD Synchronous/Async MPU/Hitachi mode

The following table gives a more detailed summary of how the signals are used in each mode. These features are also discussed in the functional description section.

Table 26-2. LCD External Signal Details

Signal	Type	Mode	Function
LCDFP (VSYNC)	Output	Raster Mode	This signal functions as a frame clock the LCD uses to signal the start of a new frame of pixels. This signal is also used by TFT displays as the vertical synchronization signal.
		LIDD Mode	This signal functions as an Address Latch Enable (ALE)
LCDLP (HSYNC)	Output	Raster Mode	This signal functions as a line clock the LCD uses to signal the end of a line of pixels. This signal is also used by TFT displays as the horizontal synchronization signal.
		LIDD Mode	This signal functions as a write strobe or direction bit depending on the interface mode.

Table 26-2. LCD External Signal Details (continued)

Signal	Type	Mode	Function
LCDCP (Pixel clock)	Output	Raster Mode	This signal functions as the pixel clock the LCD uses to clock the pixel data into the line shift register. In passive mode, the pixel clock transitions only when valid data is available on the data lines. In active mode, the pixel clock transitions continuously, and the LCDAC pin is used as an output enable to signal when data is available on the LCD pin.
		LIDD Mode	This signal functions as a read strobe (RS) or read/write strobe (RS/WS) depending on the interface mode.
LCDAC	Output	Raster Mode	This signal functions as the AC-bias used to trigger the LCD to switch the polarity of the power supplies to the row and column axis of the screen to counteract DC offset. The signal is used in TFT mode as the output enable to signal when data is latched from the data pins using the pixel clock. LIDD Character: Primary Enable Strobe (E0) LIDD Graphics: Chip Select 0 (CS0)
		LIDD Mode	This signal functions as the primary enable (E0) or Hitachi mode and the primary chip select (CS0) depending on the interface mode.
		OUT	LIDD Mode
LCDDATA	Output	Raster Mode	These signals function as the LCD data bus providing 4-, 8-, 16-, or 24-bit data path. For monochrome displays, each signal represents a pixel; for passive color displays, groupings of three signals represent one pixel (red, green, and blue). LCDDATA[3:0] are used for monochrome displays of 2, 4, and 8 BPP; LCDDATA[7:0] are used for color STN displays and LCDDATA[15:0] or LCDDATA[23:0] are used for active (TFT) mode.
	Output/Input	LIDD Mode	These signals function as the read and write path for the command and data registers.

Table 26-3 on page 1848 details MODESEL programming for the alternate pin functions in LIDD mode. For further programming information refer to the **LCDLIDDCTL** register.

Table 26-3. LCD Alternate Signal Functions in LIDD Mode

PIN	MODE = 0x0	MODE = 0x1	MODE = 0x2	MODE = 0x3	MODE = 0x4
LCDCP	RS/WS	RS/WS	RS	RS	N/A
LCDLP	DIR	DIR	WS	WS	DIR
LCDFP	ALE	ALE	ALE	ALE	ALE
LCDAC	CS0	CS0	CS0	CS0	E0
LCDMCLK	MCLK	CS1	MCLK	CS1	E1

26.3 Functional Description

The following sections describe the functional capability of the LCD Controller

26.3.1 LCD DMA Engine

The LCD DMA engine provides the capability to output graphics data to constantly refresh the external LCD display, without burdening the CPU, via interrupts or a firmware timer. It operates on one or two frame buffers, which are set up during initialization. Using two frame buffers (ping-pong buffers) enables the simultaneous operation of outputting the current video frame to the external display and updating the next video frame. The ping-pong buffering approach is preferred in most applications.

When the Raster Controller is used, the LCD DMA engine reads data from a frame buffer and writes it to the input FIFO. The Raster Controller requests data from the FIFO for frame refresh, so the DMA is used to keep the FIFO filled.

When the LIDD controller is used, the LCD DMA engine accesses the LIDD controller's address and/or data registers. The following steps are needed to configure the DMA engine:

1. Configure the data format in the **LCD DMA Control (LCDDMACTL)** register, offset 0x040.
2. Configure frame buffer 0 by programming the **LCD DMA Frame Buffer 0 Base Address (LCDDMABAFO**) register, offset 0x044, and the **LCD DMA Frame Buffer 0 Ceiling Address (LCDDMACAFB0**) register, offset 0x048
3. Configure frame buffer 1 by programming the **LCD DMA Frame Buffer 1 Base Address (LCDDMABAFO1**) register, offset 0x04C, and the **LCD DMA Frame Buffer 1 Ceiling Address (LCDDMACAFB1**) register, offset 0x050.

In addition, depending on whether the application is operating in LIDD mode or Raster Mode, the **LCDLIDDCTL** or the **LCDRASTRCTL** register should be configured appropriately, along with all of the timing registers. To enable DMA transfers, the **DMAEN** bit in the **LCDLIDDCTL** or the **LCDEN** bit in the **LCDRASTRCTL** register should be written with a 1.

26.3.1.1 Interrupts

Interrupts in this LCD module are related to DMA engine operation. Five registers are used to control and monitor the interrupts:

- **LCDLIDDCTL** and **LCDRASTRCTL** registers enable and disable individual features that can generate interrupts.
- The **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register, offset 0x058, collects all of the interrupt status information.
- The **LCD Interrupt Status and Clear (LCDMISCLR)** register, offset 0x05C, is used to read and clear the status of the masked interrupt triggers.
- The **LCD Interrupt Mask (LCDIM)** register, offset 0x060, is used to control whether an interrupt source is masked or not.

LIDD Mode

When operating in LIDD mode, the DMA engine generates one interrupt signal every time the specified frame buffer has been transferred completely. The **EOF1**, **EOF0** and **DONE** bits of the **LCDRISSET** register reflect the interrupt signal, regardless of whether or not the interrupt is enabled.

Raster Mode

When operating in Raster mode, the DMA engine can generate the interrupts in the following scenarios:

- Output FIFO under-run: This interrupt occurs when the DMA engine cannot keep up with the data rate consumed by the LCD (which is determined by the **LCDCP**.) This is likely due to a system memory throughput issue or an incorrect **LCDCP** setting. The **FIFOU** bit in **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register is set when this error occurs. This bit is cleared by disabling the Raster Controller (that is, clearing the **LCDEN** bit in **LCD Raster Control (LCDRASTRCTL)** register).

- Frame Synchronization lost: This error happens when the DMA engine attempts to read what it believes to be the first word of the video buffer but the data cannot be recognized as such. This situation can be caused by an invalid frame buffer address or an invalid BPP value. The SYNC bit in the IRQSTATUS_RAW register is set when such an error is detected. This field is cleared by disabling the Raster Controller (clearing the LCDEN bit in **LCD Raster Control (LCDRASTRCTL)** register).
- Palette loaded: This interrupt can be generated when the palette is loaded into the memory by the DMA engine. At the same time, the PALLOAD bit in the **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register is set. In data-only (PALMODE = 0x2) and palette-plus-data (PALMODE = 0x0) modes, writing 0 to this bit clears the interrupt. In the palette-only (PALMODE = 0x1) mode, this bit is cleared by disabling the Raster Controller (clearing the LCDEN bit in the **LCD Raster Control (LCDRASTRCTL)** register).
- AC Bias transition: If the ACBI field in the **LCD Raster Timing 2 (LCDRASTRTIM2)** register is programmed with a nonzero value, an internal counter is loaded with this value and starts to decrement each time LCDAC (AC-bias signal) switches its state. When the counter reaches zero, the ACBS bit in the **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register is set, which delivers an interrupt signal to the system interrupt controller (if the interrupt is enabled.) The counter reloads the value in ACBI field, but does not start to decrement until the ABC bit is cleared by writing 0 to this bit.
- Frame transfer completed: When one frame of data is transferred completely, the DONE bit in the **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register is set. This bit is cleared by disabling the Raster Controller (clearing the LCDEN bit in **LCD Raster Control (LCDRASTRCTL)** register). The EOF0 and EOF1 bits in **LCD Interrupt Raw Status and Set Register (LCDRISSET)** register are set accordingly.

Note that the function enable bits are in the **LCD Raster Control (LCDRASTRCTL)** register and must be set in order to generate an interrupt to the CPU.

26.3.2 LIDD Bus Operation

The integrated LCD Interface Display Drive (LIDD) Controller has programmable timing parameters that support a wide variety of character-based LCD panels. Alternatively, the DMA module can be used to mimic the CPU and perform a sequence of write-only data bus transactions to the character-based LCD panel.

LIDD mode is enabled by clearing the LCDMODE bit in the **LCD Control (LCDCTL)** register.

LIDD Controller operation is summarized as follows:

- During initialization, the **LCD LIDD CS0 Configuration (LIDDCS0CFG)** and **LCD LIDD CS1 Configuration (LIDDCS1CFG)** registers are configured to match the requirements of the LCD panel being used.
- During normal operation, the CPU writes display data to the **LIDD CS0 Data Read/Write Initiation (LIDDCS0DATA)** and **LIDD CS1 Data Read/Write Initiation (LIDDCS1DATA)** registers. The LIDD interface converts the CPU write into the proper signal transition sequence for the display, as programmed earlier. Note that the first CPU write should send the beginning address of the update to the LCD panel and the subsequent writes update data at display locations starting from the first address and continuing sequentially. Note that DMA may be used instead of CPU.

- The LIDD Controller is also capable of reading back status or data from the LCD panel, if the latter has this capability. This is set up and activated in a similar manner to the write function described above.

Table 26-4 on page 1851 describes how the signals are used to interface to external LCD modules, which are configured by the **LCDLIDDCTL** register.

Table 26-4. LIDD I/O Name Map

Display Type	Interface Type	Data Bits	LCDLIDDCTL[2:0]	Signal Name	LCD Display I/O Name	LCD Display I/O Description
Character Display	HD44780 Type	4	0x4	LCDDATA [7 : 4]	DATA [7 : 4]	LCD Data Bus (length defined by instruction)
				LCDAC	E (or E0)	Enable Strobe (first display)
				LCDLP	R / \overline{W}	Read/Write
				LCDFP	RS	Register Select (Data/not Instruction)
				LCDMCLK	E1	Enable Strobe (second display optional)
Character Display	HD44780 Type	8	0x4	LCDDATA [7 : 0]	DATA [7 : 0]	LCD Data Bus (length defined by instruction)
				LCDAC	E (or E0)	Enable Strobe (first display)
				LCDLP	R / \overline{W}	Read/Write
				LCDFP	RS	Register Select (Data/not Instruction)
				LCDMCLK	E1	Enable Strobe (second display optional)
Micro Interface Graphic Display	6800 Family	Up to 16	0x1	LCDDATA [15 : 0]	DATA [15 : 0]	LCD Data Bus (16 bits always available)
				LCDCP	E	Enable Clock
				LCDLP	R / \overline{W}	Read/Write
				LCDFP	A0	Address/Data Select
				LCDAC	CS (or CS0)	Chip Select (first display)
				LCDMCLK	CS1	Chip Select (second display optional)
			0x0	LCDMCLK	None	Synchronous Clock (optional)
Micro Interface Graphic Display	8080 Family	Up to 16	0x3	LCDDATA [15 : 0]	DATA [15 : 0]	LCD Data Bus (16 bits always available)
				LCDCP	RD	Read Strobe
				LCDLP	WR	Write Strobe
				LCDFP	A0	Address/Data Select
				LCDAC	CS (or CS0)	Chip Select (first display)
				LCDMCLK	CS1	Chip Select (second display optional)
			0x2	LCDMCLK	None	Synchronous Clock (optional)

26.3.3 Raster Control

The Raster mode is enabled by setting the MODESEL bit in the **LCD Control (LCDCTL)** register. The following table shows the active external signals when this mode is active:

Table 26-5. Operation Modes Supported by Raster Controller

Interface	Data Bus Width	RASTERCTRL [9, 7, 1]	Signal Name	Description
Passive (STN) Mono 4-bit	4	001	LCDDATA[3 : 0]	Data Bus
			LCDCP	Pixel Clock
			LCDLP	Horizontal clock (line clock)
			LCDFP	Vertical clock (frame clock)
			LCDAC	AC Bias
			LCDMCLK	Not used
Passive (STN) Mono 8-bit	8	101	LCDDATA[7 : 0]	Data Bus
			LCDCP	Pixel Clock
			LCDLP	Horizontal clock (line clock)
			LCDFP	Vertical clock (frame clock)
			LCDAC	AC Bias
			LCDMCLK	Not used
Passive (STN) Color	8	100	LCDDATA[7 : 0]	Data Bus
			LCDCP	Pixel Clock
			LCDLP	Horizontal clock (line clock)
			LCDFP	Vertical clock (frame clock)
			LCDAC	AC Bias
			LCDMCLK	Not used
Active (TFT) Color	16	x10	LCDDATA[15 : 0]	Data Bus
			LCDCP	Pixel Clock
			LCDLP	Horizontal clock (line clock)
			LCDFP	Vertical clock (frame clock)
			LCDAC	AC Bias
			LCDMCLK	Not used

26.3.3.1 Logical Data Path

The block diagram of the Raster controller is shown in Figure 26-1 on page 1846. Figure 26-2 on page 1853 illustrates its logical data path for various operation modes (passive (STN) versus active (TFT) and various BPP size). Figure 26-2 on page 1853 shows that:

- The gray-scaler/serializer and output FIFO blocks are bypassed in active (TFT) modes.
- The palette is bypassed in both 12- and 16-BPP modes.

Figure 26-2. LCD Raster Data Path

In summary:

- The display image is stored in frame buffers.
- The built-in DMA engine constantly transfers the data stored in the frame buffers to the input FIFO.
- The Raster Controller relays data to the external pins according to the specified format.

26.3.4 Clocking

This section details the various clocks and signals. Figure 26-3 on page 1854 shows the input and output LCD controller clocks.

Figure 26-3. Input and Output Clocks

26.3.4.1 Pixel Clock (LCDCP signal)

The pixel clock (**LCDCP**) frequency is derived from the system clock, which is the internal reference clock (MCLK) to the LCD module. The pixel clock is used by the LCD display to clock the pixel data into the line shift register. The formula used for the pixel clock is:

$$\text{LCDCP} = \text{System Clock} / \text{CLKDIV}$$

where **CLKDIV** is a field in the **LCD Control (LCDCTL)** register. The value of **CLKDIV** should not be 0 or 1 in Raster Mode. The pixel clock operates differently depending on the mode of the LCD controller:

- Passive (STN) mode: **LCDCP** only transitions when valid data is available for output. It does not transition when the horizontal clock (HSYNC) is asserted or during wait state insertion.
- Active (TFT) mode: **LCDCP** continuously toggles as long as the Raster Controller is enabled.

26.3.4.2 HSYNC Horizontal Clock (LCDLP signal)

HSYNC (**LCDLP** signal) toggles after all pixels in a horizontal line have been transmitted to the LCD and a programmable number of pixel clock wait states have elapsed both at the beginning and end of each line. The **LCD Raster Timing 0 (LCDRASTRIM0)** register, offset 0x02C, fully defines the behavior of this signal.

HSYNC can be programmed to be synchronized with the rising or falling edge of the pixel clock (**LCDCP**). The **PXLCLKCTL** and **PSYNCRF** bits in the **LCD Raster Timing 2 (LCDRASTRIM2)** register, offset 0x034, are used to configure the synchronization.

- Active (TFT) mode: The horizontal clock or the line clock is also used by TFT displays as the horizontal synchronization signal (HSYNC).

The timings of the horizontal clock (line clock) pins are programmable to support:

- Delay insertion both at the beginning and end of each line
- Line clock polarity
- Line clock pulse width, driven on rising or falling edge of pixel clock

26.3.4.3 VSYNC Vertical Clock (LCDFP signal)

VSYNC (LCDFP signal) toggles after all lines in a frame have been transmitted to the LCD and a programmable number of line clock cycles has elapsed both at the beginning and end of each frame. The **LCD Raster Timing 1 (LCDRASTRIM1)** register, offset 0x030, fully defines the behavior of this signal.

VSYNC can be programmed to be synchronized with the rising or falling edge of LCDCP pixel clock. The PXLCLKCTL and PSYNCRF bits in the **LCD Raster Timing 2 (LCDRASTRIM2)** register, offset 0x034, are used to configure the synchronization.

- Passive (STN) mode: The vertical, or frame, clock toggles during the first line of the screen.
- Active (TFT) mode: The vertical, or frame, clock is also used by TFT displays as the vertical synchronization signal (VSYNC). The timings of the vertical clock pins are programmable to support:
 - Delay insertion both at the beginning and end of each frame
 - Frame clock polarity

26.3.4.4 LCD AC Bias Enable (LCDAC)

- Passive (STN) mode: To prevent a DC charge within the screen pixels, the power and ground supplies of the display are periodically switched. The Raster Controller signals the LCD to switch the polarity by toggling this pin.
- Active (TFT) mode: This signal acts as an output enable (OE) signal. It is used to signal the external LCD that the data is valid on the data bus.

26.3.5 LCD Frame Buffer

The LCD controller has the option to use the internal SRAM memory or external memory through the EPI interface to hold the frame buffer. The frame buffer contains the palette look-up table (palette RAM) and the frame data for a given source image. In the **LCD Raster Control (LCDRASTRCTL)** register, the PALMODE bit can be configured for palette and data loading, palette loading only or data loading only.

Note: When using the LCD with EPI to interface to external memory, the external code address space 0x1000.0000 must be selected by programming the ECADR field to 0x1 in the **EPI Address Map (EPIADDRMAP)** register at EPI offset 0x01C.

The palette RAM is a programmable cross reference table that maps a small set of input codes into a larger set of output codes. For active matrix displays, the palette RAM is used only for color source images. For passive matrix displays, the palette RAM is used for both grayscale and color source images. For color components, the passive matrix mode only supports, 4 bits per color component. 1, 2, 4, and 8 bit per pixel (bpp) source images always use the palette. 12, 16, and 24 bits per pixel do not use the palette RAM, since raw data transfers occur.

The LCD palette RAM uses a 12-bit output code such that there is a possibility of 4096 color options to choose from. Depending on the bpp frame storage of palette RAM, two, four, 16, or 256 palette colors can be stored in the palette RAM.

26.3.5.1 Palette RAM Structure for 1, 2, and 4 Bits Per Pixel

When palette RAM is enabled for 1, 2, and 4 bpp frame storage, the palette buffer is 16 word entries, where the upper half of the word is unused. The first entry of the palette RAM contains the encoding for the palette type (1, 2, 3, 6, or 12/16/24) of the stored picture on bits [14:12], as well as the first input code for one palette entry (bits [11:0]). Subsequent entries only contain the input codes for next palette entries. Figure 26-4 on page 1856 shows the frame buffer structure.

Figure 26-4. Palette RAM Structure for 1, 2, and 4 Bits Per Pixel

Note that for 1 bpp source pictures, the first two palette entries are valid; for 2 bpp sources, the first four palette entry sources are valid; for 4 bpp, all 16 palette entries are valid. Even if the palette entries are not valid for a particular type, there is a fixed number of 8 words reserved for the palette RAM.

The first palette entry represents the RGB value for the source pixel encoded as 0x0. The second palette entry represents the RGB values for the source pixel encoded as 0x1, and so on, such that the sixteenth palette entry is used to represent the RGB values for a pixel encoded as 0xF.

Source data encoded as 12, 16, or 24 bpp do not use the palette RAM since the encoded data already represents the actual RGB values. However, 16 palette RAM entries still precede the picture data in this case and the first palette entry must still define the bpp in bits [14:12]. The type field encoding is defined below in Table 26-6 on page 1857.

Table 26-6. Type Encoding in Palette Entry 0 Buffer

First Palette RAM Entry [14:12]	Source Image Type
0x0	1 bpp
0x1	2 bpp
0x2	4 bpp
0x3	8 bpp
0x4	12, 16, or 24 bpp

26.3.5.2 Palette RAM Structure for 8 Bits Per Pixel

For image sources that are 8 bpp, 256 palette entries (2^8) are required. This structure of the palette RAM is similar to the one described for 1, 2, 4, or 4 bpp except that the palette requires 256 entries (128 words), instead of 16. The first palette entry again contains the "type" definition of the picture along with the RGB values in bits [11:0].

26.3.5.3 LCD RAM Configuration

The LCD RAM can be configured to hold palette only, picture data only or both palette and picture data. Depending on the mode, the RAM is used differently:

- **Palette Only:** The PALMODE field in the **LCD Raster Control (LCDRASTRCTL)** register is programmed to 0x01. If the type field in the first palette entry is for 1, 2, 4, or 12/16/24 bpp, an 8 word palette buffer will be read from DDR by the DMA. If the bpp field in the first entry is 8 bpp, a 128 word palette will be loaded by the DMA. Note that the **DMA Frame Buffer n Base Address (LCDDMABAn)** and **LCD DMA Frame Buffer n Ceiling Address (LCDMACAn)** registers must encompass the palette information size. Note that although an 8 word buffer is created for 12/16/24 bpp, it is ignored during data transfers.
- **Data Only:** When PALMODE is programmed to 0x10, the bpp field from the last palette read is used. Thus, a single palette in DDR can be associated with multiple stored pictures in DDR, enabling the palette loading to occur once (PALMODE = 0x01) and subsequent data-only frame buffers to be transferred by the DMA into the RAM (PALMODE = 0x10). For 12/16/24 bpp frames the bpp field in the previously read palette RAM buffer is irrelevant.
- **Palette and Data:** When the PALMODE encoding is 0x00, the frame buffer is comprised of palette data followed immediately by pixel information. For 12, 14, and 24 bit (packed or unpacked) raw formats, an 8 word palette is prepended to the pixel data. Thus, palette information will be read from DDR even though it is not applicable data and the configuration will look similar to Figure 26-4 on page 1856.

26.3.5.4 Raw Data and Color Component Formats

Depending on the value programmed in the raster control register you can have different color formats. Raw data formats are used for active matrix panels. The LCD controller supports, 24 bpp, 16 bpp and 12 bpp raw formats.

Note: The TYPE code in the first palette entry must be set to "1XX" for 12/16/24 bpp raw data formats.

Data Format for 24 bpp

For raw formats used in active matrix panels, the palette RAM provides a 12 bpp output, or a color depth of 12 bits (4096 colors per pixel). Data formats of 24 bpp can be stored in packed or unpacked

format. In packed format, four 24 bit pixels are stored in 3 contiguous 32-bit words (also called a quad-pixel triplet) in DDR, as show in Figure 26-5 on page 1858.

Figure 26-5. 24 bpp Packed Data Format

When using a 24 bit packed format, four consecutive pixels provide three word-aligned accesses for the DMA. If the **MSBPPL** and **PPL** bits in the **LCDRASTRTIM0** register are programmed to a multiple of 16, then the **MSBLPP** and **LPP** bits of the **LCDRASTRTIM1** and **LCDRASTRTIM2** register must follow a multiple of 16 so that the DMA can access the data using word-aligned accesses.

When **LCDTFT** = 0x1, **TFT24UPCK** = 0x1 and **TFT24** = 0x1 in the **LCDRASTRCTL** register, 24 bit unpacked format is used. In this mode, each 24 bpp data is stored in a 32 bit word, with the upper 8 bits unused. Figure 26-6 on page 1858 shows the unpacked implementation.

Figure 26-6. 24 bpp Unpacked Data Format

For 24 bpp color components, data is stored in the DDR in B-G-R order with each color representing 8 bits. When the data is transferred to the LCD pixel data bus (LCDDATA[23:0]), the output is transposed such that a portion of the color components are now displayed on LCDDATA [15:0] in RGB565 format. The three least significant bits of the RGB 24-bit data are prepended to RGB565 data on LCDDATA[23:15]. The transposition of data is shown in Figure 26-7 on page 1859.

Figure 26-7. 24 bpp Color RGB Remapping on LCDDATA[23:0]**Data format for 16 bpp**

The LCD controller is configured to support 16 bpp raw data format when TFT24 = 0x0, LCDTFT = 0x1, TFTMAP = 0x0 in the **LCDRASTRCTL** register. Two 16 bpp raw data pixels can be stored in one word in DDR. The configuration is shown in Figure 26-8 on page 1859. For color component ordering, pixel data is in a RGB565 configuration and is output on the LCD pixel data bus LCDDATA[15:0] in the same order. LCDDATA bits [23:16] are undefined in 16 bpp mode. Figure 26-9 on page 1859 shows the configuration of the pixel data retrieved from memory and LCD bus output.

Figure 26-8. 16 bpp Data Format**Figure 26-9. 16 bpp Color Component Ordering****Data Format for 12 bpp**

Two pixel data are stored in each 32-bit word in memory. The upper four bits in each 16-bit halfword are unused. Figure 26-10 on page 1860 shows the 12bpp data format.

Figure 26-10. 12 bpp Data Format

12 bpp color format has 4 pixels per Red, Green and Blue color component. The BGR configuration is output on LCDDATA [11:0] as shown in Figure 26-11 on page 1860. LCDDATA [23:12] are unused.

Figure 26-11. 12 bpp Color Component Ordering

1/2/4/8 bpp Data Format

The Palette frame buffer for 1/2/4/8 bpp data supports passive and active matrix displays. Active matrix is enabled by setting the TFT bit in the **LCD Raster Control (LCDRASTRCTL)** register. When the TFTMAP is set to 0, the output from the palette look-up is a 12 bpp BGR pixel as shown in Figure 26-4 on page 1856, where each color is a 4 bit value. This output is sent to LCDDATA [11:0]. By setting TFTMAP to 1, the pixel data output is converted to a 16-bit BGR565 format. The extra least significant are dithered by replication of the component values' most significant bits. This conversion is shown in Figure 26-12 on page 1860.

Figure 26-12. 1/2/4/8 bpp Dither Output

26.3.6 Palette

As explained in the previous section, the pixel data is an index of palette entry (when palette is used). The number of colors supported is given by 2number of BPP. However, due to a limitation of the grayscaler/ serializer block, fewer grayscales or colors may be supported.

The PALMODE field in the **LCD Raster Control (LCDRASTRCTL)** register affects the palette loading:

- If PALMODE is 0x0 (palette-plus-data mode) or 0x1 (palette-only mode), the palette is loaded by the DMA engine at the very beginning, which is followed by the loading of pixel data.
- If PALMODE is 0x2 (data-only mode), the palette is not loaded. Instead, the DMA engine loads the pixel data immediately.

26.3.7 Gray-Scaler/Serializer - Passive (STN) Mode

Once a palette entry is selected from the look-up palette by the pixel data, its content is sent to the grayscaler/ serializer. If it is monochrome data, it is encoded as 4 bits. If it is color data, it is encoded as 4 bits (Red), 4 bits (Green), and 4 bits (Blue). These 4-bit values are used to select one of the 16 intensity levels, as shown in Table 13-10. A patented algorithm is used during this processing to provide an optimized intensity value that matches the eye's visual perception of color/gray gradations.

26.3.8 Gray-Scaler/Serializer - Active (TFT) Mode

The gray-scaler(serializer is bypassed in this mode.

26.3.9 Color/Grayscale Intensities and Modulation Rates

The following table details the intensities and modulation rates for varying dither values.

Table 26-7. Intensities and Modulation Rates

Dither Value (4-Bit Value from Palette)	Intensity (0% is White)	Modulation Rate (Ratio of ON to ON+OFF Pixels)
0x0	0.0%	0
0x1	14.3%	1/7
0x2	20.0%	1/5
0x3	25%	1/4
0x4	33.3%	3/9
0x5	40.0%	2/5
0x6	44.4%	4/9
0x7	50.0%	1/2
0x8	55.6%	5/9
0x9	60.0%	3/5
0xA	66.6%	6/9
0xB	75%	3/4
0xC	80.0%	4/5
0xD	85.7%	6/7
0xE	93.3%	14/15
0xF	100.0%	1

26.3.10 Summary of Color Depth

summarizes the color depths depending on the number of BPP.

Table 26-8. Number of Colors/Shades of Gray Available on Screen

Number of BPP	Passive Mode (LCDTFT = 0)		Active Mode (LCDTFT = 1)
	Monochrome (LCDBW = 1)	Color (LCDBW = 0)	Color Only (LCDBW = 0)
1	2 palette entries to select within 15 grayscales	2 palette entries to select within 3375 possible colors	2 palette entries to select within 4096 possible colors
2	4 palette entries to select within 15 grayscales	4 palette entries to select within 3375 possible colors	4 palette entries to select within 4096 possible colors
4	16 palette entries to select within 15 grayscales	16 palette entries to select within 3375 possible colors	16 palette entries to select within 4096 possible colors
8	Not relevant because it would consist in 256 palette entries to select within 15 grayscales, but exists anyways	256 palette entries to select within 3375 possible colors	256 palette entries to select within 4096 possible colors
12	X	3375 possible colors	4096 possible colors
16	X	3375 possible colors (STN_565 = 1)	Up to 65536 possible colors
24	X	X	Up to 16.7 million colors

26.3.11 Output Format

The following section describes the output format for both passive and active LCD modes.

26.3.11.1 Passive (STN) Mode

As shown in Figure 26-13 on page 1863, the pixel data stored in frame buffers go through palette (if applicable) and grayscaler/ serializer before reaching the Output FIFO. As a result, it is likely that the data fed to the output FIFO is numerically different from the data in the frame buffers. (However, they represent the same color or grayscale.)

The output FIFO formats the received data according to display modes (see Table 13-7). Figure 26-13 on page 1863, shows the actual data output on the external pins.

26.3.11.2 Active (TFT) Mode

As shown in Figure 26-13 on page 1863, the gray-scaler/serializer and output FIFO are bypassed in active (TFT) mode. Namely, at each pixel clock, one pixel data (16 bits) is output to the external LCD.

Figure 26-13. Monochrome and Color Output

26.3.12 Subpicture Feature

A feature exists in the LCD to cover either the top or lower portion of the display with a default color. This feature is called a subpicture and is illustrated in Figure 26-14 on page 1864. Subpictures are only allowed for Active Matrix Mode (when **LCDTFT = 0x1** in the **LCD Raster Control (LCDRASTRCTL)** register).

Subpicture reduce the bandwidth since lines containing default pixel data are not read from memory. For example, suppose the panel has 100 lines of which 50 are default pixel data lines. Then, only 50 lines of data are DMAed from DDR for this subpicture setup. That is, the **LCD DMA Frame Buffer n Base Address (LCDDMABAFBn)** and **LCD DMA Frame Buffer n Base Address (LCDDMABAFBn)** registers only encompass 50 lines of data instead of 100.

Figure 26-14. Example of Subpicture

The subpicture feature is enabled when the SPEN control bit in the **LCD Raster Subpanel Display n (LCDRASTRSUBPn)** register is set to 1. The HOLS bit, when programmed to 0, puts the Default Pixel Data lines at the top of the screen and the active video lines at the bottom of the screen. When the HOLS bit is set to 1, Active video lines are at the top of the screen and Default Pixel Data lines are at the bottom of the screen. The HOLS bit behavior is shown in Figure 26-15 on page 1864.

Figure 26-15. Subpicture Output with HOLS Bit Variations

The LPPT (lines per panel threshold) bitfield defines the number of lines at the bottom of the picture for both HOLS = 1 or 0. LPPT is an encoded value in the range {0:2047} used to represent the number of lines in the range {1:2048}.

26.4 Interrupts

The application can program the LCD controller to trigger an interrupt for the following events:

- DMA end-of-frame 1: The DMA end-of-frame 1 (EOF1) interrupt is triggered when the DMA module has completed transferring the contents of a bounded frame buffer 1.
- DMA end-of-frame 0: The DMA end-of-frame 0 (EOF0) interrupt is triggered when the DMA module has completed transferring the contents of a bounded frame buffer 0.
- DMA palette loaded: When PALMODE is set to Palette-only or Palette+data, the palette loaded interrupt is triggered when the palette portion of the DMA transfer has been stored in the Palette RAM.

- DMA FIFO Underflow: The FIFO Underflow (**FIFOU**) interrupt is triggered when the real-time output needs to send a value for pixel data but one cannot be found in the FIFO.
- AC Bias Count Decrement to Zero: For Passive Matrix displays, a count can be kept of the number of times the AC Bias line toggles. Once the specified number of transitions has been seen, the AC Bias Count (**ACBS**) interrupt is triggered. The module does not post any further interrupts or keep counting AC Bias transitions until the interrupt has been cleared.
- Frame synchronization lost: When the DMA module reads a frame buffer and stores it in the FIFO, it sets a start frame and an end frame indicator embedded with the data. On retrieving the data from the FIFO, the Sync Lost (**SYNCS**) interrupt is triggered if the start indicator is not found at the first pixel of a new frame.
- Recurrent Raster mode frame done: In raster mode, the Recurrent Frame Done (**RRASTRDONE**) interrupt is triggered each time a complete frame has been sent to the interface pins.
- Raster or LIDD frame done (shared interrupt): In LIDD DMA mode, a frame buffer of data is sent. When the frame buffer has completed, the LIDD Frame Done (**DONE**) interrupt is triggered. In order to do another LIDD DMA, the DMA engine must be disabled and then re-enabled.

In Raster mode, the interrupt is triggered after LCDEN bit is programmed to 0 in the **LCD Raster Control (LCDRASTRCTL)** register and after the last frame is sent to the pins. After the Raster mode DMA is running, the interrupt occurs only once after the module is disabled.

The interrupts are enabled in the **LCD Interrupt Mask register (LCDIM)** register. All pending interrupts in the LCD module must be serviced by the Host's Interrupt Service Routine before it exits.

26.5 Bus Transaction Modes

The LCD Controller supports character-based LCD panels by ensuring the bus cycles for reading/writing commands and data are met. The LIDD (LCD Interface Display Driver) provides this support. The LIDD interfaces with an ARM CPU in the SOC using a VBUS slave port. Abundant programmable timing parameters can be configured such that the off-chip interface can support a wide variety of character based LCD panels. Alternatively, the DMA module can be used to mimic the CPU and perform a sequence of write-only data bus transactions to the character based LCD panel. The Motorola and Intel interfaces support asynchronous and synchronous modes. The only difference between the two is that, for synchronous mode, the internal bus clock is output on a pin that replaces CS1. In other words, only one character panel can be supported under synchronous mode while two panels can be supported for asynchronous mode.

26.6 Initialization and Configuration

Basic configuration of the LCD controller is as follows:

1. Enable the LCD Controller in the System Control module using the **RCGCLCD** register. See page 418.
2. Enable the DMA, core and LIDD controller (if required) in the **LCDCLKEN** register.
3. Select the LCD mode (LIDD or Raster) by programming the **LCDMODE** bit in the **LCDCTL** register. In addition, configure the LCDCP or LCDMCLK frequency through the **CLKDIV** field.
4. When operating in LIDD mode:

- a. Program the **LCDLIDDCTL** register along with the chip select configuration register, **LIDDCSnCFG**.
 - b. Select the DMA parameters in the **LCDDMACTL** register. Program the frame buffer boundaries in the **LCDDMABAFB0** and **LCDDMACAFB0** registers.
 - c. Enable any required interrupts in the **LCDIM** register.
 - d. Initiate LIDD mode transactions by setting the **DMAEN** bit in the **LCDLIDDCTL** register.
5. When operating in Raster Mode:
- a. Program the **LCDRASTRCTL** register along with the raster timings in the **LCDRASTRTIMn** registers.
 - b. Configure the subpanel display in the **LCDRASTRSUBPn** registers.
 - c. Select the DMA parameters such as burst size, and memory layout in the **LCDDMACTL** register. Program the frame buffer boundaries in the **LCDDMABAFBn** and **LCDDMACAFBn** registers.
 - d. Enable any required interrupts in the **LCDIM** register.
 - e. Initiate Raster mode transactions by setting the **LCDEN** bit in the **LCDRASTRCTL** register.

The LCD DMA may interface to internal SRAM or the external memory through EPI for transfer of data. To configure the EPI for use with LCD, refer to “External Peripheral Interface (EPI)” on page 844.

Note: When using the LCD with EPI to interface to external memory, the external code address space 0x1000.0000 must be selected by programming the **ECADR** field to 0x1 in the **EPI Address Map (EPIADDRMAP)** register at EPI offset 0x01C.

26.7 Register Map

Table 26-9 on page 1866 lists the LCD registers. The offset listed is a hexadecimal increment to the register's address, relative to the LCD module's base address of 0x4405.0000.

Table 26-9. LCD Register Map

Offset	Name	Type	Reset	Description	See page
0x000	LCDPID	RO	0x4F20.1000	LCD PID Register Format	1868

26.8 Register Descriptions

Following is a description of the individual registers of the LCD controller.

Register 1: LCD PID Register Format (LCDPID), offset 0x000

This register contains information regarding the Peripheral ID (PID) of the LCD module.

LCD PID Register Format (LCDPID)

Base 0x4405.0000
Offset 0x000
Type RO, reset 0x4F20.1000

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10:8	MAJOR	RO	0x0	Major Release Number This field contains the major release number for the IP.
7:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:0	MINOR	RO	0x00	Minor Release Number This field contains the minor release number for the IP.

Register 2: LCD Control (LCDCTL), offset 0x004

The **LCD Control (LCDCTL)** register configures the mode, clock frequencies and restart behavior of the LCD Controller.

LCD Control (LCDCTL)

Base 0x4405.0000
Offset 0x004
Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:16 reserved RO 0x0000 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

15:8 CLKDIV RW 0x00 Clock Divisor

This field contains a value (from 0-255) used to specify the frequency of the pixel clock, LCDCP (in Raster Mode) or MCLK (in LIDD mode). The equation for the two clock outputs is: SYSCLK/CLKDIV, where:

- LCDCP can range from SYSCLK/2 to SYSCLK/255. CLKDIV = 0x0 or CLKDIV = 0x1 are not allowed.
- MCLK can vary from SYSCLK to SYSCLK/255 (using CLKDIV = 0x0 or CLKDIV = 0x1 sets MCLK = SYSCLK).

See Table 26-10 on page 1870 for f_{SYSCLK} to f_{LCDCP} frequency conversions based on CLKDIV value.

7:2 reserved RO 0x00 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

1 UFLOWRST RW 0 Underflow Restart

Value Description

0 On an underflow, software must restart the module.

1 On an underflow, the hardware restarts the module on the next frame.

0 LCDMODE RW 0 LCD Mode Select

Value Description

0 LCD Controller is operating in LIDD Mode

1 LCD Controller is operating in Raster Mode

Table 26-10. SYSCLK to Pixel Clock (LCDCP) Frequency Conversion Table

f_{SYSCLK} (MHz)	CLKDIV Value	f_{LCDCP} (MHz)
120	2	60
	3	40
	4	30

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	DMACS	RW	0	CS0/CS1 Select for LIDD DMA Writes Value Description 0 DMA writes to LIDD CS0 (_L CDCAC). 1 DMA writes to LIDD CS1 (_L CDMCLK). Note: In Motorola 6800 or Intel 8080 synchronous modes, CS1 is not used and thus, DMACS should not be set to 0x1.
8	DMAEN	RW	0	LIDD DMA Enable Value Description 0 Deactivate DMA control of LIDD interface. DMA control is released upon completion of transfer of the current frame of data (LIDD Frame Done) when this bit is clear. The microcontroller has direct read/write access to the panel in this mode. 1 Activate DMA to drive LIDD interface to support streaming data to smart panels. The microcontroller cannot access the panel directly in this mode.
7	CS1E1	RW	0	Chip Select 1 (CS1)/Enable 1(E1) Polarity Control CS1 is active low by default. EN1 is active high by default. Value Description 0 CS1/E1 (_L CDMCLK) are not inverted. CS1 remains active low and E1 remains active high. 1 Invert CS1/E1 (_L CDMCLK). CS1 is active high and E1 is active low.

Bit/Field	Name	Type	Reset	Description
6	CS0E0	RW	0	Chip Select 0 (CS0)/Enable 0 (E0) Polarity Control CS0 is active low by default. E0 is active high by default.
				Value Description
			0	CS0/E0 (_{LCDAC}) are not inverted. CS0 remains active low and E0 remains active high.
			1	Invert CS0/E0. CS0 is active high and E0 is active low.
5	WRDIRINV	RW	0	Write Strobe (WR) /Direction (DIR) Polarity Control WR active low by default. DIR is write low/read high by default.
				Value Description
			0	WR/DIR (_{LCDLP}) are not inverted. WR remains active low and DIR is write low/read high.
			1	Invert WR/DIR. WR is active high and DIR is write high/read low.
4	RDEN	RW	0	Read Strobe (RD) /Direct Enable (EN) Polarity Control RD is active low by default. EN is active high by default.
				Value Description
			0	RD/EN (_{LCDCP}) are not inverted. RD is active low and EN is active high.
			1	Invert RD/EN (_{LCDCP}). RD is active high and EN is active low.
3	ALE	RW	0	Address Latch Enable (ALE) Polarity Control ALE is active low by default.
				Value Description
			0	ALE (_{LCDFP}) is not inverted.
			1	Invert ALE (_{LCDFP}). ALE is active high.
2:0	MODE	RW	0x0	LIDD Mode Select. Selects type of LCD display interface for the LIDD to drive. See Table 26-3 on page 1848 for external pin assignments based on MODE encoding.
				Value Description
			0x0	Synchronous Motorola 6800 Mode
			0x1	Asynchronous Motorola 6800 Mode
			0x2	Synchronous Intel 8080 mode
			0x3	Asynchronous Intel 8080 mode
			0x4	Asynchronous Hitachi mode
			0x5-0x7	reserved

The MODE bit field described above defines the function of the LCD external pins as follows:

Table 26-11. LCD Alternate Signal Functions in LIDD Mode

PIN	MODE = 0x0	MODE = 0x1	MODE = 0x2	MODE = 0x3	MODE = 0x4
LCDCP	RS/WS	RS/WS	RS	RS	N/A
LCDLP	DIR	DIR	WS	WS	DIR
LCDFP	ALE	ALE	ALE	ALE	ALE
LCDAC	CS0	CS0	CS0	CS0	E0
LCDMCLK	MCLK	CS1	MCLK	CS1	E1

Register 4: LCD LIDD CS0 Configuration (LIDDCS0CFG), offset 0x010

The **LIDD CS0 Configuration (LIDDCS0CFG)** register defines the timings for the read and write strobes with respect to CS0.

LCD LIDD CS0 Configuration (LIDDCS0CFG)

Base 0x4405.0000
Offset 0x010
Type RW, reset 0x0044.0044

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	1	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type	RW	GAP														
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	1	0	0

Bit/Field	Name	Type	Reset	Description
31:27	WRSU	RW	0x0	Write Strobe (WR) Set-Up Cycles When performing a write access, this field defines the number of MCLK cycles that the LCDDATA bus, output enable, ADE, DIR and CS0 signals have to be ready before the write strobe. The minimum value is 0x0.
26:21	WRDUR	RW	0x2	Write Strobe (WR) Duration Cycles This field value defines the number of MCLK cycles for which the write strobe is held active when performing a write access. The minimum value is 0x1.
20:17	WRHOLD	RW	0x2	Write Strobe (WR) Hold cycles. This field value defines the number of MCLK cycles for which the LCDDATA bus, output enable, ALE, DIR and CS0 signals are held after the write strobe is deasserted when performing a write access. The minimum value is 0x1.
16:12	RDSU	RW	0x0	Read Strobe (RD) Set-Up cycles. When performing a read access, this field defines the number of MCLK cycles that the LCDDATA bus, output enable, ALE, DIR and CS0 signals have to be ready before the read strobe is asserted.
11:6	RDDUR	RW	0x1	Read Strobe (RD) Duration cycles. This field defines the number of MCLK cycles for which the read strobe is held active when performing a read access. The minimum value is 0x1.
5:2	RDHOLD	RW	0x1	Read Strobe (RD) Hold cycles. This field defines of MCLK cycles for which the LCDDATA bus, output enable, ALE, DIR and CS0 signals are held after the read strobe is deasserted when performing a read access. The minimum value is 0x1.
1:0	GAP	RW	0x0	Field value defines the number of LCDMCLK cycles (GAP +1) between the end of one CS0 (LCDAC) device access and the start of another CS0 (LCDAC) device access unless the two accesses are both reads. In this case, this delay is not incurred. The minimum value is 0x0.

Register 5: LIDD CS0 Read/Write Address (LIDDCS0ADDR), offset 0x014

This register contains the read and write address of the current access enabled by CS0 (LCDAC).

LIDD CS0 Read/Write Address (LIDDCS0ADDR)

Base 0x4405.0000
Offset 0x014
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	CS0ADDR	RW	0x0000	<p>LCD Address</p> <p>The LCD Controller supports a shared Address/Data output bus. A write to this register initiates a bus write transaction. A read from this register initiates a bus read transaction.</p> <p>CPU reads and writes to this register are not permitted if the LIDD module is in DMA mode (DMAEN bit set in the LIDDCTRL register). If the LIDD is being used as a generic bus interface, writing to this register can store CS0ADDR to an external transparent latch holding a 16-bit address.</p> <p>If the LIDD is being used to interface with a character based LCD panel in Hitachi configuration mode, reading and writing to this register can be used to access the command instruction area of the panel.</p>

Register 6: LIDD CS0 Data Read/Write Initiation (LIDDCS0DATA), offset 0x018

This register contains the read and write data of the current access enabled by CS0 (LCDAC).

LIDD CS0 Data Read/Write Initiation (LIDDCS0DATA)

Base 0x4405.0000
Offset 0x018
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	CS0DATA	RW	0x0000	<p>LCD Data Read/Write</p> <p>The LCD Controller supports a shared Address/Data output bus. A write to this register initiates a bus write transaction. A read from this register initiates a bus read transaction.</p> <p>CPU reads and writes to this register are not permitted if the LIDD module is in DMA mode (DMAEN bit set in the LIDDCTRL register).</p> <p>If the LIDD is being used as a generic bus interface, writing to this register can store CS0ADDR to an external transparent latch holding a 16-bit address.</p> <p>If the LIDD is being used to interface with a character based LCD panel in Hitachi configuration mode, reading and writing to this register can be used to access the data area of the panel.</p>

Register 7: LIDD CS1 Configuration (LIDDCS1CFG), offset 0x01C

The **LIDD CS1 Configuration (LIDDCS1CFG)** register defines the timings for the read and write strobes with respect to CS1.

LIDD CS1 Configuration (LIDDCS1CFG)

Base 0x4405.0000
Offset 0x01C
Type RW, reset 0x0044.0044

Bit/Field	Name	Type	Reset	Description
31:27	WRSU	RW	0x0	Write Strobe (WR) Set-Up Cycles When performing a write access, this field defines the number of LCDMCLK cycles that Data Bus/Pad Output Enable, ALE, DIR, and CS1 have to be ready before WR (LCDLP) is asserted. The minimum value is 0x0.
26:21	WRDUR	RW	0x2	Write Strobe (WR) Duration Cycles Field value defines the number of LCDMCLK cycles for which WR (LCDLP) is held active when performing a write access. The minimum value is 0x1.
20:17	WRHOLD	RW	0x2	Write Strobe (WR) Hold cycles. Field value defines the number of LCDMCLK cycles for which Data Bus/Pad Output Enable, ALE, the DIR, and CS1 signals are held after WR (LCDLP) is deasserted when performing a write access. The minimum value is 0x1.
16:12	RDSU	RW	0x0	Read Strobe (RD) Set-Up cycles. When performing a read access, this field defines the number of LCDMCLK cycles that Data Bus/Pad Output Enable, ALE, the DIR, and CS1 signals have to be ready before RD (LCDCP) is asserted.
11:6	RDDUR	RW	0x1	Read Strobe (RD) Duration cycles. Field value defines the number of LCDMCLK cycles for which RD (LCDCP) is held active when performing a read access. The minimum value is 0x1.
5:2	RDHOLD	RW	0x1	Read Strobe (RD) Hold cycles. Field value defines the number of LCDMCLK cycles for which Data Bus/Pad Output Enable, ALE, DIR, and CS1 signals are held after RD (LCDCP) is deasserted when performing a read access. The minimum value is 0x1.
1:0	GAP	RW	0x0	Field value defines the number of LCDMCLK cycles (GAP + 1) between the end of one CS1 (LCDAC) device access and the start of another CS0 (LCDAC) device access unless the two accesses are both reads. In this case, this delay is not incurred. The minimum value is 0x0.

Register 8: LIDD CS1 Address Read/Write Initiation (LIDDCS1ADDR), offset 0x020

This register contains the read and write address of the current access enabled by CS1 (LCDAC).

LIDD CS1 Address Read/Write Initiation (LIDDCS1ADDR)

Bit/Field	Name	Type	Reset	Description						
19:12	REQDLY	RW	0x00	<p>Palette Loading Delay</p> <p>This 8-bit parameter pauses reading of the Palette data from the asynchronous FIFO between each burst of 16 words. The delay is in terms of system clock (SYSCLK) cycles. The value (0-255) used to specify the number of system clock cycles that should be paused between bursts of 16 word reads from the asynchronous FIFO while loading the Palette SRAM. Programming <code>REQDLY=0x00</code> disables this pause when loading the Palette table.</p> <p>When loading the Palette from system memory, palette data is burst into the internal Palette SRAM from the Asynchronous FIFO. 1, 2, and 4-bit per pixel frame buffer encodings use a fixed 16-word entry palette residing above the video data.</p> <p>The 8-bit per pixel frame buffer encoding uses a 256-word entry palette residing above the video data. Likewise, 12, 16, and 24-bit per pixel frame buffer encodings also define a 256-word entry palette even though these encodings will not do a full bit-depth palette lookup. However, the 256-word palette entry must still be read from DDR as a frame buffer is fetched.</p> <p>Bursting in 256 words in sequential SYSCLK cycles may cause the asynchronous FIFO to underflow depending on the DDR burst bandwidth.</p>

LCD Raster Timing 0 (LCDRASTRTIM0)

Base 0x4405.0000
Offset 0x02C
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:24	HBP	RW	0x00	Horizontal Back Porch Lowbits Bits 7:0 of the horizontal back porch field. Encoded value (from 1-1024) used to specify the number of pixel clock periods to add to the beginning of a line transmission before the first set of pixels is output to the display (programmed value plus 1). Note that pixel clock is held in its inactive state during the beginning of the line wait period in passive display mode, and is permitted to transition in active display mode.
23:16	HFP	RW	0x00	Horizontal Front Porch Lowbits Encoded value (from 1-1024) used to specify the number of pixel clock periods to add to the end of a line transmission before line clock is asserted (programmed value plus 1). Note that pixel clock is held in its inactive state during the end of line wait period in passive display mode, and is permitted to transition in active display mode.
15:10	HSW	RW	0x00	Horizontal Sync Pulse Width Lowbits Bits 5:0 of the horizontal sync pulse width field. Encoded value (from 1-1024) used to specify the number of pixel clock periods to pulse the line clock at the end of each line (programmed value plus 1). Note that pixel clock is held in its inactive state during the generation of line clock in passive display mode, and is permitted to transition in active display mode.
9:4	PPL	RW	0x00	Pixels-per-line LSB[9:4] The PPL field is set to the (number of horizontal pixels -1) divided by 16.
3	MSBPPL	RW	0	Pixels-per-line MSB[10] Needed in order to support up to 2048 ppl.
2:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 12: LCD Raster Timing 1 (LCDRASTRTIM1), offset 0x030

LCD Raster Timing 1 (LCDRASTRTIM1)

Base 0x4405.0000
Offset 0x030
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:24	VBP	RW	0x00	Vertical Back Porch Value (from 0-255) use to specify the number of line clock periods to add to the beginning of a frame before the first set of pixels is output to the display. Note that line clock transitions during the insertion of the extra line clock periods.
23:16	VFP	RW	0x00	Vertical Front Porch Value (from 0-255) used to specify the number of line clock periods to add to the end of each frame. Note that the line clock transitions during the insertion of the extra line clock periods.
15:10	VSW	RW	0x00	Vertical Sync Width Pulse In active mode (<code>LCDTFT=1</code>), encoded value (from 1-64) used to specify the number of line clock periods to set the <code>lcd_fp</code> pin active at the end of each frame after the (vfp) period elapses. The number of clock cycles is programmed value plus one. The frame clock is used as the VSYNC signal in active mode. In passive mode (<code>LCDTFT=0</code>), encoded value (from 1-64) used to specify the number of extra line clock periods to insert after the vertical front porch (vfp) period has elapsed. Note that the width of <code>lcd_fp</code> is not affected by vsw in passive mode and line clock transitions during the insertion of the extra line clock periods (programmed value plus one).
9:0	LPP	RW	0x00	Lines Per Panel Encoded value (programmed value range of {0:2047} represents an actual range of {1:2048}) used to specify the number of lines per panel. It represents the total number of lines on the LCD (programmed value plus one). Bit 10 of this field is in LCDRASTRIM2 .

8	LPPTMSB	RW	0	Lines Per Panel Threshold Bit 10 This register is Bit 10 of the LPPT field in LCDRASTRSUBP1 .
7:0	DPDMSB	RW	0x00	Default Pixel Data MSB [23:16] DPD defines the default value of the pixel data sent to the panel for the lines until LPPT is reached or after passing the LPPT.

Register 16: LCD DMA Control (LCDDMACTL), offset 0x040

LCD DMA Control (LCDDMACTL)

Base 0x4405.0000
Offset 0x040
Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10:8	FIFORDY	RW	0x0	DMA FIFO threshold. The DMA FIFO becomes ready when the number of words specified by this register from the frame buffer have been loaded.
		Value	Description	
		0x0	8 words	
		0x1	16 words	
		0x2	32 words	
		0x3	64 words	
		0x4	128 words	
		0x5	256 words	
		0x6	512 words	
		0x7	reserved	
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:4	BURSTSZ	RW	0x0	Burst Size setting for DMA transfers (all DMA transfers are 32 bits wide):
		Value	Description	
		0x0-0x1	reserved	
		0x2	burst size of 4	
		0x3	burst size of 8	
		0x4	burst size of 16	
		0x5-0x7	reserved	

Note: For Raster Mode, configuring BURSTSZ should be done only after an LCD peripheral reset using the **SRLCD** register in System Control. The BURSTSZ field should not be changed once the LCD DMA is enabled.

Bit/Field	Name	Type	Reset	Description
3	BYTESWAP	RW	0	This bit controls the bytelane ordering of the data on the output of the DMA module. It works in conjunction with the big-endian bit. See the big-endian description for configuration guidelines.
2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BIGDEND	RW	0	Big Endian Enable Use this bit when the processor is operating in Big Endian mode and writes to the frame buffers are less than 32-bits wide. Only in this scenario do we need to change the byte alignment for data coming into the FIFO from the frame buffer. Value Description 0 Big Endian reordering disabled. 1 Big Endian reordering enabled.
				The BIGEND and BYTESWAP bits control the byte lane ordering of the data on the output of the DMA module.
0	FMODE	RW	0	Frame Mode Value Description 0 One frame buffer (FB0 only) used 1 Two frame buffers used,. DMA ping-pongs between FB0 and FB1 in this mode

2	DMA	RW	0	Software Reset for the DMA submodule. This reset affects the L3 clk domain. Value Description 0 Reset Disabled 1 Reset Enabled
1	LIDD	RW	0	Software Reset for the LIDD submodule (character displays). This reset affects the LIDD logic in the lcd_clk domain. Value Description 0 Reset Disabled 1 Reset Enabled
0	CORE	RW	0	Software Reset for the Core, which encompasses the Raster Active Matrix and Passive Matrix logic. This reset affects the Core (active matrix and passive matrix raster mode) logic in the lcd_clk domain. Value Description 0 Reset Disabled 1 Reset Enabled

27 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result.

Note: Not all comparators have the option to drive an output pin. See “Signal Description” on page 1914 for more information.

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board. In addition, the comparator can signal the application via interrupts or trigger the start of a sample sequence in the ADC. The interrupt generation and ADC triggering logic is separate and independent. This flexibility means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The TM4C129XKCZAD microcontroller provides three independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
 - An individual external reference voltage
 - A shared single external reference voltage
 - A shared internal reference voltage

27.1 Block Diagram

Figure 27-1. Analog Comparator Module Block Diagram

Note: This block diagram depicts the maximum number of analog comparators and comparator outputs for the family of microcontrollers; the number for this specific device may vary. See page 1927 for what is included on this device.

27.2 Signal Description

The following table lists the external signals of the Analog Comparators and describes the function of each. The Analog Comparator output signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the Analog Comparator signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the Analog Comparator function. The number in parentheses is the encoding that must be programmed into the **PMCN** field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the Analog Comparator signal to the specified GPIO port pin. The positive and negative input signals are configured by clearing the **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769.

Table 27-1. Analog Comparators Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
C0+	L2	PC6	I	Analog	Analog comparator 0 positive input.

Table 27-1. Analog Comparators Signals (212BGA) (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
C0-	K3	PC7	I	Analog	Analog comparator 0 negative input.
C0o	C2 G18	PD0 (5) PL2 (5)	O	TTL	Analog comparator 0 output.
C1+	M1	PC5	I	Analog	Analog comparator 1 positive input.
C1-	M2	PC4	I	Analog	Analog comparator 1 negative input.
C1o	C1 J18	PD1 (5) PL3 (5)	O	TTL	Analog comparator 1 output.
C2+	D6	PP0	I	Analog	Analog comparator 2 positive input.
C2-	D7	PP1	I	Analog	Analog comparator 2 negative input.
C2o	D2	PD2 (5)	O	TTL	Analog comparator 2 output.

27.3 Functional Description

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

```
VIN- < VIN+, VOUT = 1
VIN- > VIN+, VOUT = 0
```

As shown in Figure 27-2 on page 1915, the input source for VIN- is an external input, Cn-, where n is the analog comparator number. In addition to an external input, Cn+, input sources for VIN+ can be the C0+ or an internal reference, V_{REF}.

Figure 27-2. Structure of Comparator Unit

A comparator is configured through two status/control registers, **Analog Comparator Control (ACCTL)** and **Analog Comparator Status (ACSTAT)**. The internal reference is configured through one control register, **Analog Comparator Reference Voltage Control (ACREFCTL)**. Interrupt status and control are configured through three registers, **Analog Comparator Masked Interrupt Status (ACMIS)**, **Analog Comparator Raw Interrupt Status (ACRIS)**, and **Analog Comparator Interrupt Enable (ACINTEN)**.

Typically, the comparator output is used internally to generate an interrupt as controlled by the ISEN bit in the **ACCTL** register. The output may also be used to drive one of the external pins (Cno), or generate an analog-to-digital converter (ADC) trigger.

Important: The ASRCP bits in the **ACCTL** register must be set before using the analog comparators.

27.3.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 27-3 on page 1916. The internal reference is controlled by a single configuration register (**ACREFCTL**).

Figure 27-3. Comparator Internal Reference Structure

Note: In the figure above, N^*R represents a multiple of the R value that produces the results specified in Table 27-2 on page 1916.

The internal reference can be programmed in one of two modes (low range or high range) depending on the **RNG** bit in the **ACREFCTL** register. When **RNG** is clear, the internal reference is in high-range mode, and when **RNG** is set the internal reference is in low-range mode.

In each range, the internal reference, V_{REF} , has 16 preprogrammed thresholds or step values. The threshold to be used to compare the external input voltage against is selected using the **VREF** field in the **ACREFCTL** register.

In the high-range mode, the V_{REF} threshold voltages start at the ideal high-range starting voltage of $V_{\text{DDA}}/4.2$ and increase in ideal constant voltage steps of $V_{\text{DDA}}/29.4$.

In the low-range mode, the V_{REF} threshold voltages start at 0 V and increase in ideal constant voltage steps of $V_{\text{DDA}}/22.12$. The ideal V_{REF} step voltages for each mode and their dependence on the **RNG** and **VREF** fields are summarized in Table 27-2.

Table 27-2. Internal Reference Voltage and ACREFCTL Field Values

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value
EN Bit Value	RNG Bit Value	
EN=0	RNG=X	0 V (GND) for any value of VREF. It is recommended that RNG=1 and VREF=0 to minimize noise on the reference ground.

Table 27-2. Internal Reference Voltage and ACREFCTL Field Values (continued)

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value	
EN Bit Value	RNG Bit Value		
EN=1	RNG=0	V _{IREF} High Range: 16 voltage threshold values indexed by VREF = 0x0 .. 0xF Ideal starting voltage (VREF=0): V _{DDA} / 4.2 Ideal step size: V _{DDA} / 29.4 Ideal V _{IREF} threshold values: V _{IREF} (VREF) = V _{DDA} / 4.2 + VREF * (V _{DDA} / 29.4), for VREF = 0x0 .. 0xF For minimum and maximum V _{IREF} threshold values, see Table 27-3 on page 1917.	
	RNG=1	V _{IREF} Low Range: 16 voltage threshold values indexed by VREF = 0x0 .. 0xF Ideal starting voltage (VREF=0): 0 V Ideal step size: V _{DDA} / 22.12 Ideal V _{IREF} threshold values: V _{IREF} (VREF) = VREF * (V _{DDA} / 22.12), for VREF = 0x0 .. 0xF For minimum and maximum V _{IREF} threshold values, see Table 27-4 on page 1918.	

Note that the values shown in Table 27-2 are the ideal values of the V_{IREF} thresholds. These values actually vary between minimum and maximum values for each threshold step, depending on process and temperature. The minimum and maximum values for each step are given by:

- V_{IREF(VREF)} [Min] = Ideal V_{IREF(VREF)} – (Ideal Step size – 2 mV) / 2
- V_{IREF(VREF)} [Max] = Ideal V_{IREF(VREF)} + (Ideal Step size – 2 mV) / 2

Examples of minimum and maximum V_{IREF} values for V_{DDA} = 3.3V for high and low ranges, are shown in Table 27-3 and Table 27-4. Note that these examples are only valid for V_{DDA} = 3.3V; values scale up and down with V_{DDA}.

Table 27-3. Analog Comparator Voltage Reference Characteristics, V_{DDA} = 3.3V, EN= 1, and RNG = 0

VREF Value	V _{IREF} Min	Ideal V _{IREF}	V _{IREF} Max	Unit
0x0	0.731	0.786	0.841	V
0x1	0.843	0.898	0.953	V

27.4 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator clock by writing a value of 0x0000.0001 to the **RCGCACMP** register in the System Control module (see page 413).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 398). To find out which GPIO ports to enable, refer to Table 31-5 on page 2085.
3. In the GPIO module, enable the GPIO port/pin associated with the input signals as GPIO inputs. To determine which GPIO to configure, see Table 31-4 on page 2068.
4. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the analog comparator output signals to the appropriate pins (see page 816 and Table 31-5 on page 2085).
5. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
6. Configure the comparator to use the internal voltage reference and to *not* invert the output by writing the **ACCTLn** register with the value 0x0000.040C.
7. Delay for 10 μ s.
8. Read the comparator output value by reading the **ACSTATn** register's OVAL value.

Change the level of the comparator negative input signal C- to see the OVAL value change.

27.5 Register Map

Table 27-5 on page 1919 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 413). There must be a delay of 3 system clocks after the analog comparator module clock is enabled before any analog comparator module registers are accessed.

Table 27-5. Analog Comparators Register Map

Offset	Name	Type	Reset	Description	See page
0x000	ACMIS	RW1C	0x0000.0000	Analog Comparator Masked Interrupt Status	1920

27.6 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x000

This register provides a summary of the interrupt status (masked) of the comparators.

Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000
Offset 0x000
Type RW1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved																
Type	RO	RO	RO													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
reserved																
Type	RO	RW1C	RW1C	RW1C												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	IN2	RW1C	0	Comparator 2 Masked Interrupt Status
	Value	Description		
	0	No interrupt has occurred or the interrupt is masked.		
	1	The IN2 bits in the ACRIS register and the ACINTEN registers are set, providing an interrupt to the interrupt controller.		
	This bit is cleared by writing a 1. Clearing this bit also clears the IN2 bit in the ACRIS register.			
1	IN1	RW1C	0	Comparator 1 Masked Interrupt Status
	Value	Description		
	0	No interrupt has occurred or the interrupt is masked.		
	1	The IN1 bits in the ACRIS register and the ACINTEN registers are set, providing an interrupt to the interrupt controller.		
	This bit is cleared by writing a 1. Clearing this bit also clears the IN1 bit in the ACRIS register.			
0	IN0	RW1C	0	Comparator 0 Masked Interrupt Status
	Value	Description		
	0	No interrupt has occurred or the interrupt is masked.		
	1	The IN0 bits in the ACRIS register and the ACINTEN registers are set, providing an interrupt to the interrupt controller.		
	This bit is cleared by writing a 1. Clearing this bit also clears the IN0 bit in the ACRIS register.			

Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x004

This register provides a summary of the interrupt status (raw) of the comparators. The bits in this register must be enabled to generate interrupts using the **ACINTEN** register.

Analog Comparator Raw Interrupt Status (ACRIS)

Base 0x4003.C000
Offset 0x004
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	IN2	RO	0	Comparator 2 Interrupt Status Value Description 0 An interrupt has not occurred. 1 Comparator 2 has generated an interrupt for an event as configured by the ISEN bit in the ACCTL2 register. This bit is cleared by writing a 1 to the IN2 bit in the ACMIS register.
1	IN1	RO	0	Comparator 1 Interrupt Status Value Description 0 An interrupt has not occurred. 1 Comparator 1 has generated an interrupt for an event as configured by the ISEN bit in the ACCTL1 register. This bit is cleared by writing a 1 to the IN1 bit in the ACMIS register.
0	IN0	RO	0	Comparator 0 Interrupt Status Value Description 0 An interrupt has not occurred. 1 Comparator 0 has generated an interrupt for an event as configured by the ISEN bit in the ACCTL0 register. This bit is cleared by writing a 1 to the IN0 bit in the ACMIS register.

Register 3: Analog Comparator Interrupt Enable (ACINTEN), offset 0x008

This register provides the interrupt enable for the comparators.

Analog Comparator Interrupt Enable (ACINTEN)

Base 0x4003.C000
Offset 0x008
Type RW, reset 0x0000.0000

28 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The TM4C129XKCZAD microcontroller contains one PWM module, with four PWM generator blocks and a control block, for a total of 8 PWM outputs. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that share the same timer and frequency and can either be programmed with independent actions or as a single pair of complementary signals with dead-band delays inserted. The output signals, pwmA' and pwmb', of the PWM generation blocks are managed by the output control block before being passed to the device pins as MnPWM0 and MnPWM1 or MnPWM2 and MnPWM3, and so on.

The TM4C129XKCZAD PWM module provides a great deal of flexibility and can generate simple PWM signals, such as those required by a simple charge pump as well as paired PWM signals with dead-band delays, such as those required by a half-H bridge driver. Three generator blocks can also generate the full six channels of gate controls required by a 3-phase inverter bridge.

Each PWM generator block has the following features:

- Four fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled
- One 16-bit counter
 - Runs in Down or Up/Down mode
 - Output frequency controlled by a 16-bit load value
 - Load value updates can be synchronized
 - Produces output signals at zero and load value
- Two PWM comparators
 - Comparator value updates can be synchronized
 - Produces output signals on match
- PWM signal generator
 - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
 - Produces two independent PWM signals
- Dead-band generator
 - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
 - Can be bypassed, leaving input PWM signals unmodified

- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal
- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Extended PWM synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

28.1 Block Diagram

Figure 28-1 on page 1931 provides the TM4C129XKCZAD PWM module diagram and Figure 28-2 on page 1931 provides a more detailed diagram of a TM4C129XKCZAD PWM generator. The TM4C129XKCZAD controller contains four generator blocks that generate eight independent PWM signals or four paired PWM signals with dead-band delays inserted.

Figure 28-1. PWM Module Diagram**Figure 28-2. PWM Generator Block Diagram**

28.2 Signal Description

The following table lists the external signals of the PWM module and describes the function of each. The PWM controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these PWM signals. The AFSEL bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the PWM function. The number in parentheses is the encoding that must be programmed into the PMCn field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the PWM signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769.

Table 28-1. PWM Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description

28.3 Functional Description

28.3.1 Clock Configuration

The PWM has two clock source options:

- The System Clock
- A predivided System Clock

The clock source is selected by programming the USEPWM bit in the **PWM Clock Configuration (PWMC) register**. The PWMDIV bitfield specifies the divisor of the System Clock that is used to create the PWM Clock.

28.3.2 PWM Timer

The timer in each PWM generator runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse. In the figures in this chapter, these signals are labelled "dir," "zero," and "load."

28.3.3 PWM Comparators

Each PWM generator has two comparators that monitor the value of the counter; when either comparator matches the counter, they output a single-clock-cycle-width High pulse, labeled "cmpA" and "cmpB" in the figures in this chapter. When in Count-Up/Down mode, these comparators match both when counting up and when counting down, and thus are qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 28-3 on page 1934 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 28-4 on page 1934 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode. In these figures, the following definitions apply:

- LOAD is the value in the **PWMnLOAD** register
- COMPA is the value in the **PWMnCMPA** register
- COMPB is the value in the **PWMnCMPB** register
- 0 is the value zero
- load is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to the load value
- zero is the internal signal that has a single-clock-cycle-width High pulse when the counter is zero
- cmpA is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPA
- cmpB is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPB
- dir is the internal signal that indicates the count direction

Figure 28-3. PWM Count-Down Mode**Figure 28-4. PWM Count-Up/Down Mode**

28.3.4 PWM Signal Generator

Each PWM generator takes the load, zero, cmpA, and cmpB pulses (qualified by the dir signal) and generates two internal PWM signals, pwmA and pwmB. In Count-Down mode, there are four events that can affect these signals: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect these signals: zero, load, match A down, match A up, match B down, and match B up. The match A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal, pwmA, is generated based only on the match A event, and the second signal, pwmB, is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 28-5 on page 1935 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles. This figure shows the pwmA and pwmB signals before they have passed through the dead-band generator.

Figure 28-5. PWM Generation Example In Count-Up/Down Mode

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A changes the duty cycle of the pwmA signal, and changing the value of comparator B changes the duty cycle of the pwmB signal.

28.3.5 Dead-Band Generator

The pwmA and pwmB signals produced by each PWM generator are passed to the dead-band generator. If the dead-band generator is disabled, the PWM signals simply pass through to the pwmA' and pwmB' signals unmodified. If the dead-band generator is enabled, the pwmB signal is lost and two PWM signals are generated based on the pwmA signal. The first output PWM signal, pwmA' is the pwmA signal with the rising edge delayed by a programmable amount. The second output PWM signal, pwmB', is the inversion of the pwmA signal with a programmable delay added between the falling edge of the pwmA signal and the rising edge of the pwmB' signal.

The resulting signals are a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 28-6 on page 1935 shows the effect of the dead-band generator on the pwmA signal and the resulting pwmA' and pwmB' signals that are transmitted to the output control block.

Figure 28-6. PWM Dead-Band Generator

28.3.6 Interrupt/ADC-Trigger Selector

Each PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position

within the pwmA or pwmB signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

28.3.7 Synchronization Methods

The PWM module provides four PWM generators, each providing two PWM outputs that may be used in a wide variety of applications. Generally speaking, the PWM is used in one of two categories of operation:

- **Unsynchronized.** The PWM generator and its two output signals are used alone, independent of other PWM generators.
- **Synchronized.** The PWM generator and its two outputs signals are used in conjunction with other PWM generators using a common, unified time base. If multiple PWM generators are configured with the same counter load value, synchronization can be used to guarantee that they also have the same count value (the PWM generators must be configured before they are synchronized). With this feature, more than two M_n PWM $_n$ signals can be produced with a known relationship between the edges of those signals because the counters always have the same values. Other states in the module provide mechanisms to maintain the common time base and mutual synchronization.

The counter in a PWM generator can be reset to zero by writing the **PWM Time Base Sync (PWMSYNC)** register and setting the `SYNC n` bit associated with the generator. Multiple PWM generators can be synchronized together by setting all necessary `SYNC n` bits in one access. For example, setting the `SYNC0` and `SYNC1` bits in the **PWMSYNC** register causes the counters in PWM generators 0 and 1 to reset together.

Additional synchronization can occur between multiple PWM generators by updating register contents in one of the following three ways:

- **Immediately.** The write value has immediate effect, and the hardware reacts immediately.
- **Locally Synchronized.** The write value does not affect the logic until the counter reaches the value zero at the end of the PWM cycle. In this case, the effect of the write is deferred, providing a guaranteed defined behavior and preventing overly short or overly long output PWM pulses.
- **Globally Synchronized.** The write value does not affect the logic until two sequential events have occurred: (1) the Update mode for the generator function is programmed for global synchronization in the **PWM n CTL** register, and (2) the counter reaches zero at the end of the PWM cycle. In this case, the effect of the write is deferred until the end of the PWM cycle following the end of all updates. This mode allows multiple items in multiple PWM generators to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values. The Update mode of the load and comparator match values can be individually configured in each PWM generator block. It typically makes sense to use the synchronous update mechanism across PWM generator blocks when the timers in those blocks are synchronized, although this is not required in order for this mechanism to function properly.

The following registers provide either local or global synchronization based on the state of various Update mode bits and fields in the **PWM n CTL** register (`LOADUPD`; `CMPAUPD`; `CMPBUPD`):

- Generator Registers: **PWM n LOAD**, **PWM n CMPA**, and **PWM n CMPB**

The following registers default to immediate update, but are provided with the optional functionality of synchronously updating rather than having all updates take immediate effect:

- Module-Level Register: **PWMENABLE** (based on the state of the ENUPD_n bits in the PWMENUPD register).
- Generator Register: **PWMnGENA**, **PWMnGENB**, **PWMnDBCTL**, **PWMnDBRISE**, and **PWMnDBFALL** (based on the state of various Update mode bits and fields in the **PWMnCTL** register (GENAUPD; GENBUPD; DBCTLUPD; DBRISEUPD; DBFALLUPD)).

All other registers are considered statically provisioned for the execution of an application or are used dynamically for purposes unrelated to maintaining synchronization and therefore do not need synchronous update functionality.

28.3.8 Fault Conditions

A fault condition is one in which the controller must be signaled to stop normal PWM function and then set the MnPWM_n signals to a safe state. Two basic situations cause fault conditions:

- The microcontroller is stalled and cannot perform the necessary computation in the time required for motion control
- An external error or event is detected

The PWM generator can use the following inputs to generate a fault condition, including:

- MnFAULT_n pin assertion
- A stall of the controller generated by the debugger
- The trigger of an ADC digital comparator

Fault conditions are calculated on a per-PWM generator basis. Each PWM generator configures the necessary conditions to indicate a fault condition exists. This method allows the development of applications with dependent and independent control.

Four fault input pins (MnFAULT_n) are available. These inputs may be used with circuits that generate an active High or active Low signal to indicate an error condition. A MnFAULT_n pins may be individually programmed for the appropriate logic sense using the **PWMnFLTSEN** register.

The PWM generator's mode control, including fault condition handling, is provided in the **PWMnCTL** register. This register determines whether the input or a combination of MnFAULT_n input signals and/or digital comparator triggers (as configured by the **PWMnFLTSRC0** and **PWMnFLTSRC1** registers) is used to generate a fault condition. The **PWMnCTL** register also selects whether the fault condition is maintained as long as the external condition lasts or if it is latched until the fault condition until cleared by software. Finally, this register also enables a counter that may be used to extend the period of a fault condition for external events to assure that the duration is a minimum length. The minimum fault period count is specified in the **PWMnMINFLTPER** register.

Note: When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the **PWMnCTL** register should be set to 1 to ensure trigger assertions are captured.

Status regarding the specific fault cause is provided in the **PWMnFLTSTAT0** and **PWMnFLTSTAT1** registers. Note that the fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

PWM generator fault conditions may be promoted to a controller interrupt using the **PWMINTEN** register.

28.3.9 Output Control Block

The output control block takes care of the final conditioning of the pwmA' and pwmB' signals before they go to the pins as the MnPWMn signals. Via a single register, the **PWM Output Enable (PWNENABLE)** register, the set of PWM signals that are actually enabled to the pins can be modified. This function can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). In addition, the updating of the bits in the **PWMENABLE** register can be configured to be immediate or locally or globally synchronized to the next synchronous update using the **PWM Enable Update (PWMENUPD)** register.

During fault conditions, the PWM output signals, MnPWMn , usually must be driven to safe values so that external equipment may be safely controlled. The **PWMFAULT** register specifies whether during a fault condition, the generated signal continues to be passed driven or to an encoding specified in the **PWMFAULTVAL** register.

A final inversion can be applied to any of the MnPWMn signals, making them active Low instead of the default active High using the **PWM Output Inversion (PWMINVERT)**. The inversion is applied even if a value has been enabled in the **PWMFAULT** register and specified in the **PWMFAULTVAL** register. In other words, if a bit is set in the **PWMFAULT**, **PWMFAULTVAL**, and **PWMINVERT** registers, the output on the MnPWMn signal is 0, not 1 as specified in the **PWMFAULTVAL** register.

28.4 Initialization and Configuration

The following example shows how to initialize PWM Generator 0 with a 25-kHz frequency, a 25% duty cycle on the MnPWM0 pin, and a 75% duty cycle on the MnPWM1 pin. This example assumes the system clock is 20 MHz.

1. Enable the PWM clock by setting its corresponding bit in the **RCGCPWM** register in the System Control module (see page 414).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 398).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 31-4 on page 2068.
4. Configure the PMC_n fields in the **GPIOPCTL** register to assign the PWM signals to the appropriate pins (see page 816 and Table 31-5 on page 2085).
5. Configure the **PWM Clock Configuration (PWMCC)** register to use the PWM divide (**USEPWMDIV**) and set the divider (**PWMDIV**) to divide by 2 (0x0).
6. Configure the PWM generator for countdown mode with immediate updates to the parameters.
 - Write the **PWM0CTL** register with a value of 0x0000.0000.
 - Write the **PWM0GENA** register with a value of 0x0000.008C.
 - Write the **PWM0GENB** register with a value of 0x0000.080C.
7. Set the period. For a 25-KHz frequency, the period = 1/25,000, or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. Thus there are 400 clock ticks per period. Use this value to set the **PWM0LOAD** register. In Count-Down mode, set the **LOAD** field in the **PWM0LOAD** register to the requested period minus one.

- Write the **PWM0LOAD** register with a value of 0x0000.018F.
- 8. Set the pulse width of the MnPWM0 pin for a 25% duty cycle.
 - Write the **PWM0CMPA** register with a value of 0x0000.012B.
- 9. Set the pulse width of the MnPWM1 pin for a 75% duty cycle.
 - Write the **PWM0CMPB** register with a value of 0x0000.0063.
- 10. Start the timers in PWM generator 0.
 - Write the **PWM0CTL** register with a value of 0x0000.0001.
- 11. Enable PWM outputs.
 - Write the **PWMENABLE** register with a value of 0x0000.0003.

28.5 Register Map

Table 28-2 on page 1939 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM module's base address:

- PWM0: 0x4002.8000

Note that the PWM module clock must be enabled before the registers can be programmed. There must be a delay of 3 system clocks after the PWM module clock is enabled before any PWM module registers are accessed.

28.6 Register Descriptions

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

Register 1: PWM Master Control (PWMCTL), offset 0x000

This register provides master control over the PWM generation blocks.

PWM Master Control (PWMCTL)

PWM0 base: 0x4002.8000

Offset 0x000

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	GLOBALSYNC3	RW	0	Update PWM Generator 3
	Value	Description		
	0	No effect.		
	1	Any queued update to a load or comparator register in PWM generator 3 is applied the next time the corresponding counter becomes zero.		
				This bit automatically clears when the updates have completed; it cannot be cleared by software.
2	GLOBALSYNC2	RW	0	Update PWM Generator 2
	Value	Description		
	0	No effect.		
	1	Any queued update to a load or comparator register in PWM generator 2 is applied the next time the corresponding counter becomes zero.		
				This bit automatically clears when the updates have completed; it cannot be cleared by software.

Bit/Field	Name	Type	Reset	Description
1	GLOBALSYNC1	RW	0	<p>Update PWM Generator 1</p> <p>Value Description</p> <p>0 No effect.</p> <p>1 Any queued update to a load or comparator register in PWM generator 1 is applied the next time the corresponding counter becomes zero.</p> <p>This bit automatically clears when the updates have completed; it cannot be cleared by software.</p>
0	GLOBALSYNC0	RW	0	<p>Update PWM Generator 0</p> <p>Value Description</p> <p>0 No effect.</p> <p>1 Any queued update to a load or comparator register in PWM generator 0 is applied the next time the corresponding counter becomes zero.</p> <p>This bit automatically clears when the updates have completed; it cannot be cleared by software.</p>

Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Setting a bit in this register causes the specified counter to reset back to 0; setting multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

PWM Time Base Sync (PWMSYNC)

PWM0 base: 0x4002.8000

Offset 0x004

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	SYNC3	RW	0	Reset Generator 3 Counter Value Description 0 No effect. 1 Resets the PWM generator 3 counter.
2	SYNC2	RW	0	Reset Generator 2 Counter Value Description 0 No effect. 1 Resets the PWM generator 2 counter.
1	SYNC1	RW	0	Reset Generator 1 Counter Value Description 0 No effect. 1 Resets the PWM generator 1 counter.
0	SYNC0	RW	0	Reset Generator 0 Counter Value Description 0 No effect. 1 Resets the PWM generator 0 counter.

Register 3: PWM Output Enable (PWMMENABLE), offset 0x008

This register provides a master control of which generated pwmA' and pwmB' signals are output to the MnPWMn pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding pwmA' or pwmB' signal is passed through to the output stage. When bits are clear, the pwmA' or pwmB' signal is replaced by a zero value which is also passed to the output stage. The **PWMINVERT** register controls the output stage, so if the corresponding bit is set in that register, the value seen on the MnPWMn signal is inverted from what is configured by the bits in this register. Updates to the bits in this register can be immediate or locally or globally synchronized to the next synchronous update as controlled by the ENUPDn fields in the **PWMENUPD** register.

PWM Output Enable (PWMMENABLE)

PWM0 base: 0x4002.8000

Offset 0x008

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	PWM7EN	RW	0	MnPWM7 Output Enable
		Value	Description	
		0	The MnPWM7 signal has a zero value.	
		1	The generated pwm3B' signal is passed to the MnPWM7 pin.	
6	PWM6EN	RW	0	MnPWM6 Output Enable
		Value	Description	
		0	The MnPWM6 signal has a zero value.	
		1	The generated pwm3A' signal is passed to the MnPWM6 pin.	
5	PWM5EN	RW	0	MnPWM5 Output Enable
		Value	Description	
		0	The MnPWM5 signal has a zero value.	
		1	The generated pwm2B' signal is passed to the MnPWM5 pin.	

Bit/Field	Name	Type	Reset	Description
4	PWM4EN	RW	0	MnPWM4 Output Enable Value Description 0 The MnPWM4 signal has a zero value. 1 The generated pwm2A' signal is passed to the MnPWM4 pin.
3	PWM3EN	RW	0	MnPWM3 Output Enable Value Description 0 The MnPWM3 signal has a zero value. 1 The generated pwm1B' signal is passed to the MnPWM3 pin.
2	PWM2EN	RW	0	MnPWM2 Output Enable Value Description 0 The MnPWM2 signal has a zero value. 1 The generated pwm1A' signal is passed to the MnPWM2 pin.
1	PWM1EN	RW	0	MnPWM1 Output Enable Value Description 0 The MnPWM1 signal has a zero value. 1 The generated pwm0B' signal is passed to the MnPWM1 pin.
0	PWM0EN	RW	0	MnPWM0 Output Enable Value Description 0 The MnPWM0 signal has a zero value. 1 The generated pwm0A' signal is passed to the MnPWM0 pin.

Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C

This register provides a master control of the polarity of the MnPWMn signals on the device pins. The pwmA' and pwmB' signals generated by the PWM generator are active High; but can be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive signals can be High. In addition, if the **PWMFAULT** register enables a specific value to be placed on the MnPWMn signals during a fault condition, that value is inverted if the corresponding bit in this register is set.

PWM Output Inversion (PWMINVERT)

Register 5: PWM Output Fault (PWMFAULT), offset 0x010

This register controls the behavior of the M_n PWM n outputs in the presence of fault conditions. Both the fault inputs (M_n FAULT n pins and digital comparator outputs) and debug events are considered fault conditions. On a fault condition, each pwmA' or pwmB' signal can be passed through unmodified or driven to the value specified by the corresponding bit in the **PWMFAULTVAL** register. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the pwmA' or pwmB' signal continues to be generated.

Fault condition control occurs before the output inverter, so PWM signals driven to a specified value on fault are inverted if the channel is configured for inversion (therefore, the pin is driven to the logical complement of the specified value on a fault condition).

Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014

This register controls the global interrupt generation capabilities of the PWM module. The events that can cause an interrupt are the fault input and the individual interrupts from the PWM generators.

Note: The "n" in the INTFAULTn and INTPWMn bits in this register correspond to the PWM generators, not to the FAULTn signals.

Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018

This register provides the current set of interrupt sources that are asserted, regardless of whether they are enabled to cause an interrupt to be asserted to the interrupt controller. The fault interrupt is asserted based on the fault condition source that is specified by the **PWMnCTL**, **PWMnFLTSRC0** and **PWMnFLTSRC1** registers. The fault interrupt is latched on detection and must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register. The actual value of the MnFAULTn signals can be observed using the **PWMSTATUS** register.

The PWM generator interrupts simply reflect the status of the PWM generators and are cleared via the interrupt status register in the PWM generator blocks. If a bit is set, the event is active; if a bit is clear the event is not active.

PWM Raw Interrupt Status (PWMRIS)

0	INTPWM0	RO	0	PWM0 Interrupt Asserted
Value Description				
			0	The PWM generator 0 block interrupt has not been asserted.
			1	The PWM generator 0 block interrupt is asserted.

The **PWM0RIS** register shows the source of this interrupt. This bit is cleared by writing a 1 to the corresponding bit in the **PWM0ISC** register.

Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the individual PWM generator blocks. If a fault interrupt is set, the corresponding MnFAULTn input has caused an interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status. If an block interrupt bit is set, the corresponding generator block is asserting an interrupt. The individual interrupt status registers, **PWMnISC**, in each block must be consulted to determine the reason for the interrupt and used to clear the interrupt.

Value Description				
		0		The PWM generator 0 block interrupt is not asserted or is not enabled.
		1		An enabled interrupt for the PWM generator 0 block is asserted.

The **PWM0RIS** register shows the source of this interrupt. This bit is cleared by writing a 1 to the corresponding bit in the **PWM0ISC** register.

Register 9: PWM Status (PWMSTATUS), offset 0x020

This register provides the unlatched status of the PWM generator fault condition.

PWM Status (PWMSTATUS)

PWM0 base: 0x4002.8000

Offset 0x020

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	FAULT3	RO	0	Generator 3 Fault Status
		Value	Description	
		0	The fault condition for PWM generator 3 is not asserted.	
		1	The fault condition for PWM generator 3 is asserted. If the FLTSRC bit in the PWM3CTL register is clear, the input is the source of the fault condition, and is therefore asserted.	
2	FAULT2	RO	0	Generator 2 Fault Status
		Value	Description	
		0	The fault condition for PWM generator 2 is not asserted.	
		1	The fault condition for PWM generator 2 is asserted. If the FLTSRC bit in the PWM2CTL register is clear, the input is the source of the fault condition, and is therefore asserted.	
1	FAULT1	RO	0	Generator 1 Fault Status
		Value	Description	
		0	The fault condition for PWM generator 1 is not asserted.	
		1	The fault condition for PWM generator 1 is asserted. If the FLTSRC bit in the PWM1CTL register is clear, the input is the source of the fault condition, and is therefore asserted.	

Bit/Field	Name	Type	Reset	Description
0	FAULT0	RO	0	Generator 0 Fault Status
Value Description				
		0		The fault condition for PWM generator 0 is not asserted.
		1		The fault condition for PWM generator 0 is asserted. If the FLTSRC bit in the PWM0CTL register is clear, the input is the source of the fault condition, and is therefore asserted.

Register 10: PWM Fault Condition Value (PWMFAULTVAL), offset 0x024

This register specifies the output value driven on the M_n PWM $_n$ signals during a fault condition if enabled by the corresponding bit in the **PWMFAULT** register. Note that if the corresponding bit in the **PWMINVERT** register is set, the output value is driven to the logical NOT of the bit value in this register.

PWM Fault Condition Value (PWMFAULTVAL)

Register 12: PWM0 Control (PWM0CTL), offset 0x040**Register 13: PWM1 Control (PWM1CTL), offset 0x080****Register 14: PWM2 Control (PWM2CTL), offset 0x0C0****Register 15: PWM3 Control (PWM3CTL), offset 0x100**

These registers configure the PWM signal generation blocks (PWM0CTL controls the PWM generator 0 block, and so on). The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via these registers. The blocks produce the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the M_n PWM0 and M_n PWM1 outputs, the PWM1 block produces the M_n PWM2 and M_n PWM3 outputs, the PWM2 block produces the M_n PWM4 and M_n PWM5 outputs, and the PWM3 block produces the M_n PWM6 and M_n PWM7 outputs.

18	LATCH	RW	0	Latch Fault Input
		Value	Description	
		0	Fault Condition Not Latched	A fault condition is in effect for as long as the generating source is asserting.
		1	Fault Condition Latched	A fault condition is set as the result of the assertion of the faulting source and is held (latched) while the PWMISC .INTFAULT n bit is set. Clearing the INTFAULT n bit clears the fault condition.

Note: When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the PWMMnCTL register should be set to 1 to ensure trigger assertions are captured.

Bit/Field	Name	Type	Reset	Description																
17	MINFLTPER	RW	0	<p>Minimum Fault Period</p> <p>This bit specifies that the PWM generator enables a one-shot counter to provide a minimum fault condition period.</p> <p>The timer begins counting on the rising edge of the fault condition to extend the condition for a minimum duration of the count value. The timer ignores the state of the fault condition while counting.</p> <p>The minimum fault delay is in effect only when the MINFLTPER bit is set. If a detected fault is in the process of being extended when the MINFLTPER bit is cleared, the fault condition extension is aborted.</p> <p>The delay time is specified by the PWMnMINFLTPER register MFP field value. The effect of this is to pulse stretch the fault condition input.</p> <p>The delay value is defined by the PWM clock period. Because the fault input is not synchronized to the PWM clock, the period of the time is PWMClock * (MFP value + 1) or PWMClock * (MFP value + 2).</p> <p>The delay function makes sense only if the fault source is unlatched. A latched fault source makes the fault condition appear asserted until cleared by software and negates the utility of the extend feature. It applies to all fault condition sources as specified in the FLTSRC field.</p>																
				<table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The FAULT input deassertion is unaffected.</td></tr> <tr> <td>1</td><td>The PWMnMINFLTPER one-shot counter is active and extends the period of the fault condition to a minimum period.</td></tr> </tbody> </table> <p>Note: When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the PWMnCTL register should be set to 1 to ensure trigger assertions are captured.</p>	Value	Description	0	The FAULT input deassertion is unaffected.	1	The PWMnMINFLTPER one-shot counter is active and extends the period of the fault condition to a minimum period.

Register 16: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044**Register 17: PWM1 Interrupt and Trigger Enable (PWM1INTEN), offset 0x084****Register 18: PWM2 Interrupt and Trigger Enable (PWM2INTEN), offset 0x0C4****Register 19: PWM3 Interrupt and Trigger Enable (PWM3INTEN), offset 0x104**

These registers control the interrupt and ADC trigger generation capabilities of the PWM generators (**PWM0INTEN** controls the PWM generator 0 block, and so on). The events that can cause an interrupt, or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the **PWMnCMPA** register while counting up
- The counter being equal to the **PWMnCMPA** register while counting down
- The counter being equal to the **PWMnCMPB** register while counting up
- The counter being equal to the **PWMnCMPB** register while counting down

Any combination of these events can generate either an interrupt or an ADC trigger, though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified. The **PWMnRIS** register provides information about which events have caused raw interrupts.

Register 20: PWM0 Raw Interrupt Status (PWM0RIS), offset 0x048**Register 21: PWM1 Raw Interrupt Status (PWM1RIS), offset 0x088****Register 22: PWM2 Raw Interrupt Status (PWM2RIS), offset 0x0C8****Register 23: PWM3 Raw Interrupt Status (PWM3RIS), offset 0x108**

These registers provide the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (**PWM0RIS** controls the PWM generator 0 block, and so on). If a bit is set, the event has occurred; if a bit is clear, the event has not occurred. Bits in this register are cleared by writing a 1 to the corresponding bit in the **PWMnISC** register.

Register 24: PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C**Register 25: PWM1 Interrupt Status and Clear (PWM1ISC), offset 0x08C****Register 26: PWM2 Interrupt Status and Clear (PWM2ISC), offset 0x0CC****Register 27: PWM3 Interrupt Status and Clear (PWM3ISC), offset 0x10C**

These registers provide the current set of interrupt sources that are asserted to the interrupt controller (**PWM0ISC** controls the PWM generator 0 block, and so on). A bit is set if the event has occurred and is enabled in the **PWMnINTEN** register; if a bit is clear, the event has not occurred or is not enabled. These are RW1C registers; writing a 1 to a bit position clears the corresponding interrupt reason.

Note: The interrupt status can only be cleared one PWM Clock cycle after the interrupt occurs. The larger the PWM Clock Divider (**PWMDIV**) value in **PWMCC** register, the longer the system delay is to clear the interrupt.

PWMn Interrupt Status and Clear (PWMnISC)

Register 28: PWM0 Load (PWM0LOAD), offset 0x050**Register 29: PWM1 Load (PWM1LOAD), offset 0x090****Register 30: PWM2 Load (PWM2LOAD), offset 0x0D0****Register 31: PWM3 Load (PWM3LOAD), offset 0x110**

These registers contain the load value for the PWM counter (**PWM0LOAD** controls the PWM generator 0 block, and so on). Based on the counter mode configured by the **MODE** bit in the **PWMnCTL** register, this value is either loaded into the counter after it reaches zero or is the limit of up-counting after which the counter decrements back to zero. When this value matches the counter, a pulse is output which can be configured to drive the generation of the **pwmA** and/or **pwmB** signal (via the **PWMnGENA/PWMnGENB** register) or drive an interruptor ADC trigger (via the **PWMnINTEN** register).

If the Load Value Update mode is locally synchronized (based on the **LOADUPD** field encoding in the **PWMnCTL** register), the 16-bit **LOAD** value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCCTL)** register (see page 1943). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

PWMn Load (PWMnLOAD)

PWM0 base: 0x4002.8000

Offset 0x050

Type RW, reset 0x0000.0000

reserved															
Type	RO														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
LOAD															
Type	RW														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	LOAD	RW	0x0000	Counter Load Value The counter load value.

Register 32: PWM0 Counter (PWM0COUNT), offset 0x054

Register 33: PWM1 Counter (PWM1COUNT), offset 0x094

Register 34: PWM2 Counter (PWM2COUNT), offset 0x0D4

Register 35: PWM3 Counter (PWM3COUNT), offset 0x114

These registers contain the current value of the PWM counter (**PWM0COUNT** is the value of the PWM generator 0 block, and so on). When this value matches zero or the value in the **PWMnLOAD**, **PWMnCMPA**, or **PWMnCMPB** registers, a pulse is output which can be configured to drive the generation of a PWM signal or drive an interrupt or ADC trigger.

Note: Disabling the PWM by clearing the `ENABLE` bit does not clear the `COUNT` field of the **PWMnCOUNT** register. Before re-enabling the PWM (`ENABLE = 0x1`), the `COUNT` field should be cleared by resetting the PWM registers through the **SRPWM** register in the System Control Module.

PWMn Counter (PWMnCOUNT)

PWM0 base: 0x4002.8000

Offset 0x054

Offset 0x034
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	COUNT	RO	0x0000	Counter Value The current value of the counter.

Register 36: PWM0 Compare A (PWM0CMPA), offset 0x058**Register 37: PWM1 Compare A (PWM1CMPA), offset 0x098****Register 38: PWM2 Compare A (PWM2CMPA), offset 0x0D8****Register 39: PWM3 Compare A (PWM3CMPA), offset 0x118**

These registers contain a value to be compared against the counter (PWM0CMPA controls the PWM generator 0 block, and so on). When this value matches the counter, a pulse is output which can be configured to drive the generation of the pwmA and pwmB signals (via the **PWMnGENA** and **PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register (see page 1980), then no pulse is ever output.

If the comparator A update mode is locally synchronized (based on the CMPAUPD bit in the **PWMnCTL** register), the 16-bit COMPA value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1943). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWMn Compare A (PWMnCMPA)

Offset 0x058

Type RW, reset 0x0000.0000

reserved															
Type	RO														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
COMPA															
Type	RW														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	COMPA	RW	0x00	Comparator A Value The value to be compared against the counter.

Register 40: PWM0 Compare B (PWM0CMPB), offset 0x05C

Register 41: PWM1 Compare B (PWM1CMPB), offset 0x09C

Register 42: PWM2 Compare B (PWM2CMPB), offset 0x0DC

Register 43: PWM3 Compare B (PWM3CMPB), offset 0x11C

These registers contain a value to be compared against the counter (**PWM0CMPB** controls the PWM generator 0 block, and so on). When this value matches the counter, a pulse is output which can be configured to drive the generation of the pwmA and pwmB signals (via the **PWMnGENA** and **PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register, no pulse is ever output.

If the comparator B update mode is locally synchronized (based on the CMPBUPD bit in the **PWMnCTL** register), the 16-bit COMPB value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1943). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWMn Compare B (PWMnCMPB)

PWM0 base: 0x4002.8000

Offset 0x05C

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	COMPB	RW	0x0000	Comparator B Value The value to be compared against the counter.

Register 44: PWM0 Generator A Control (PWM0GENA), offset 0x060**Register 45: PWM1 Generator A Control (PWM1GENA), offset 0x0A0****Register 46: PWM2 Generator A Control (PWM2GENA), offset 0x0E0****Register 47: PWM3 Generator A Control (PWM3GENA), offset 0x120**

These registers control the generation of the pwmA signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENA** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENA** register controls generation of the pwm0A signal; **PWM1GENA**, the pwm1A signal; **PWM2GENA**, the pwm2A signal; and **PWM3GENA**, the pwm3A signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

If the Generator A update mode is immediate (based on the GENAUPD field encoding in the **PWMnCTL** register), the ACTCMPBD, ACTCMPBU, ACTCMPAD, ACTCMPPAU, ACTLOAD, and ACTZERO values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1943). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Register 48: PWM0 Generator B Control (PWM0GENB), offset 0x064**Register 49: PWM1 Generator B Control (PWM1GENB), offset 0x0A4****Register 50: PWM2 Generator B Control (PWM2GENB), offset 0x0E4****Register 51: PWM3 Generator B Control (PWM3GENB), offset 0x124**

These registers control the generation of the pwmB signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENB** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENB** register controls generation of the pwm0B signal; **PWM1GENB**, the pwm1B signal; **PWM2GENB**, the pwm2B signal; and **PWM3GENB**, the pwm3B signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare B action is taken and the compare A action is ignored.

If the Generator B update mode is immediate (based on the GENBUPD field encoding in the **PWMnCTL** register), the ACTCMPBD, ACTCMPBU, ACTCMPAD, ACTCMPPAU, ACTLOAD, and ACTZERO values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1943). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Register 52: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068**Register 53: PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8****Register 54: PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8****Register 55: PWM3 Dead-Band Control (PWM3DBCTL), offset 0x128**

The **PWMnDBCTL** register controls the dead-band generator, which produces the M_nPWM_n signals based on the pwmA and pwmB signals. When disabled, the pwmA signal passes through to the pwmA' signal and the pwmB signal passes through to the pwmB' signal. When dead-band control is enabled, the pwmB signal is ignored, the pwmA' signal is generated by delaying the rising edge(s) of the pwmA signal by the value in the **PWMnDBRISE** register (see page 1991), and the pwmB' signal is generated by inverting the pwmA signal and delaying the falling edge(s) of the pwmA signal by the value in the **PWMnDBFALL** register (see page 1992). The Output Control block outputs the pwm0A' signal on the M_nPWM_0 signal and the pwm0B' signal on the M_nPWM_1 signal. In a similar manner, M_nPWM_2 and M_nPWM_3 are produced from the pwm1A' and pwm1B' signals, M_nPWM_4 and M_nPWM_5 are produced from the pwm2A' and pwm2B' signals, and M_nPWM_6 and M_nPWM_7 are produced from the pwm3A' and pwm3B' signals.

If the Dead-Band Control mode is immediate (based on the DBCTLUPD field encoding in the **PWMnCTL** register), the **ENABLE** bit value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1943). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWMn Dead-Band Control (PWMnDBCTL)

0	ENABLE	RW	0	Dead-Band Generator Enable
				Value Description
			0	The pwmA and pwmB signals pass through to the pwmA' and pwmB' signals unmodified.
			1	The dead-band generator modifies the pwmA signal by inserting dead bands into the pwmA' and pwmB' signals.

Register 56: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C

Register 57: PWM1 Dead-Band Rising-Edge Delay (PWM1DBRISE), offset 0x0AC

Register 58: PWM2 Dead-Band Rising-Edge Delay (PWM2DBRISE), offset 0x0EC

Register 59: PWM3 Dead-Band Rising-Edge Delay (PWM3DBRISE), offset 0x12C

The **PWMnDBRISE** register contains the number of clock cycles to delay the rising edge of the pwmA signal when generating the pwmA' signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a High pulse on the pwmA signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the pwmA High time always exceeds the rising-edge delay.

If the Dead-Band Rising-Edge Delay mode is immediate (based on the DBRISEUPD field encoding in the **PWMnCTL** register), the 12-bit RISEDELAY value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1943). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWMn Dead-Band Rising-Edge Delay (PWMnDBRISE)

PWM0 base: 0x4002.8000

Offset 0x06C

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	RISEDELAY	RW	0x000	Dead-Band Rise Delay The number of clock cycles to delay the rising edge of pwmA' after the rising edge of pwmA.

Register 60: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070

Register 61: PWM1 Dead-Band Falling-Edge-Delay (PWM1DBFALL), offset 0x0B0

Register 62: PWM2 Dead-Band Falling-Edge-Delay (PWM2DBFALL), offset 0x0F0

Register 63: PWM3 Dead-Band Falling-Edge-Delay (PWM3DBFALL), offset 0x130

The **PWMnDBFALL** register contains the number of clock cycles to delay the rising edge of the pwb' signal from the falling edge of the pwmA signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a Low pulse on the pwmA signal, the falling-edge delay consumes the entire Low time of the signal, resulting in no Low time on the output. Care must be taken to ensure that the pwmA Low time always exceeds the falling-edge delay.

If the Dead-Band Falling-Edge-Delay mode is immediate (based on the DBFALLUP field encoding in the **PWMnCTL** register), the 12-bit FALDELAY value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1943). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Note: The FLTSRC bit in the PWMnCTL register must be set for this bit to affect fault condition generation.

Register 72: PWM0 Minimum Fault Period (PWM0MINFLTPER), offset 0x07C**Register 73: PWM1 Minimum Fault Period (PWM1MINFLTPER), offset 0x0BC****Register 74: PWM2 Minimum Fault Period (PWM2MINFLTPER), offset 0x0FC****Register 75: PWM3 Minimum Fault Period (PWM3MINFLTPER), offset 0x13C**

If the MINFLTPER bit in the **PWMnCTL** register is set, this register specifies the 16-bit time-extension value to be used in extending the fault condition. The value is loaded into a 16-bit down counter, and the counter value is used to extend the fault condition. The fault condition is released in the clock immediately after the counter value reaches 0. The fault condition is asynchronous to the PWM clock; and the delay value is the product of the PWM clock period and the (MFP field value + 1) or (MFP field value + 2) depending on when the fault condition asserts with respect to the PWM clock. The counter decrements at the PWM clock rate, without pause or condition.

PWM_n Minimum Fault Period (PWM_nMINFLTPER)

Register 80: PWM0 Fault Status 0 (PWM0FLTSTAT0), offset 0x804**Register 81: PWM1 Fault Status 0 (PWM1FLTSTAT0), offset 0x884****Register 82: PWM2 Fault Status 0 (PWM2FLTSTAT0), offset 0x904****Register 83: PWM3 Fault Status 0 (PWM3FLTSTAT0), offset 0x984**

Along with the **PWMnFLTSTAT1** register, this register provides status regarding the fault condition inputs.

If the **LATCH** bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT0** register are read-only (RO) and provide the current state of the **MnFAULTn** inputs.

If the **LATCH** bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT0** register are read / write 1 to clear (RW1C) and provide a latched version of the **MnFAULTn** inputs. In this mode, the register bits are cleared by writing a 1 to a set bit. The **MnFAULTn** inputs are recorded after their sense is adjusted in the generator.

The contents of this register can only be written if the fault source extensions are enabled (the **FLTSRC** bit in the **PWMnCTL** register is set).

Note: The fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

Register 84: PWM0 Fault Status 1 (PWM0FLTSTAT1), offset 0x808**Register 85: PWM1 Fault Status 1 (PWM1FLTSTAT1), offset 0x888****Register 86: PWM2 Fault Status 1 (PWM2FLTSTAT1), offset 0x908****Register 87: PWM3 Fault Status 1 (PWM3FLTSTAT1), offset 0x988**

Along with the **PWMnFLTSTAT0** register, this register provides status regarding the fault condition inputs.

If the **LATCH** bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT1** register are read-only (RO) and provide the current state of the digital comparator triggers.

If the **LATCH** bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT1** register are read / write 1 to clear (RW1C) and provide a latched version of the digital comparator triggers. In this mode, the register bits are cleared by writing a 1 to a set bit. The contents of this register can only be written if the fault source extensions are enabled (the **FLTSRC** bit in the **PWMnCTL** register is set).

Note: The fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

29 Quadrature Encoder Interface (QEI)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, you can track the position, direction of rotation, and speed. In addition, a third channel, or index signal, can be used to reset the position counter.

The TM4C129XKCZAD quadrature encoder interface (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The TM4C129XKCZAD microcontroller includes one QEI module with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
 - Index pulse
 - Velocity-timer expiration
 - Direction change
 - Quadrature error detection

29.1 Block Diagram

Figure 29-1 on page 2009 provides an internal block diagram of a TM4C129XKCZAD QEI module. The PhA and PhB inputs shown in this diagram are the internal signals that enter the Quadrature Encoder after the external signals, PhAn and PhBn, have passed through inversion and swapping logic shown in Figure 29-2 on page 2010. The QEI module has the option of inverting and/or swapping the incoming signals.

Note: Any references in this chapter to PhA and PhB refer to the internal PhA and PhB inputs that enter the Quadrature Encoder after the external signals, PhAn and PhBn, have passed through inversion and swapping logic that is enabled through the **QEI Control (QEICCTL)** register.

Figure 29-1. QEI Block Diagram

Figure 29-2 on page 2010 shows the logic that is provided to allow the `PhAn` and `PhBn` signals to be inverted and/or swapped.

Figure 29-2. QEI Input Signal Logic

29.2 Signal Description

The following table lists the external signals of the QEI module and describes the function of each. The QEI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these QEI signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 799) should be set to choose the QEI function. The number in parentheses is the encoding that must be programmed into the **PMCn** field in the **GPIO Port Control (GPIOPCTL)** register (page 816) to assign the QEI signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 769.

Table 29-1. QEI Signals (212BGA)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
IDX0	J18 U10	PL3 (6) PS6 (6)	I	TTL	QEI module 0 index.
PhA0	H19 V9	PL1 (6) PS4 (6)	I	TTL	QEI module 0 phase A.
PhB0	G18 T13	PL2 (6) PS5 (6)	I	TTL	QEI module 0 phase B.

29.3 Functional Description

The QEI module interprets the two-bit gray code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The position integrator and velocity capture can be independently enabled, though the position integrator must be enabled before the velocity capture can be enabled. The two phase signals,

`PhAn` and `PhBn`, can be swapped before being interpreted by the QEI module to change the meaning of forward and backward and to correct for miswiring of the system. Alternatively, the phase signals can be interpreted as a clock and direction signal as output by some encoders.

The QEI module input signals have a digital noise filter on them that can be enabled to prevent spurious operation. The noise filter requires that the inputs be stable for a specified number of consecutive clock cycles before updating the edge detector. The filter is enabled by the `FILTEN` bit in the **QEI Control (QEICTL)** register. The frequency of the input update is programmable using the `FILTCNT` bit field in the **QEICTL** register.

The QEI module supports two modes of signal operation: quadrature phase mode and clock/direction mode. In quadrature phase mode, the encoder produces two clocks that are 90 degrees out of phase; the edge relationship is used to determine the direction of rotation. In clock/direction mode, the encoder produces a clock signal to indicate steps and a direction signal to indicate the direction of rotation. This mode is determined by the `SIGMODE` bit of the **QEICTL** register (see page 2015).

When the QEI module is set to use the quadrature phase mode (`SIGMODE` bit is clear), the capture mode for the position integrator can be set to update the position counter on every edge of the `PhA` signal or to update on every edge of both `PhA` and `PhB`. Updating the position counter on every `PhA` and `PhB` edge provides more positional resolution at the cost of less range in the positional counter.

When edges on `PhA` lead edges on `PhB`, the position counter is incremented. When edges on `PhB` lead edges on `PhA`, the position counter is decremented. When a rising and falling edge pair is seen on one of the phases without any edges on the other, the direction of rotation has changed.

The positional counter is automatically reset on one of two conditions: sensing the index pulse or reaching the maximum position value. The reset mode is determined by the `RESMODE` bit of the **QEICTL** register.

When `RESMODE` is set, the positional counter is reset when the index pulse is sensed. This mode limits the positional counter to the values [0:N-1], where N is the number of phase edges in a full revolution of the encoder wheel. The **QEI Maximum Position (QEIMAXPOS)** register must be programmed with N-1 so that the reverse direction from position 0 can move the position counter to N-1. In this mode, the position register contains the absolute position of the encoder relative to the index (or home) position once an index pulse has been seen.

When `RESMODE` is clear, the positional counter is constrained to the range [0:M], where M is the programmable maximum value. The index pulse is ignored by the positional counter in this mode.

Velocity capture uses a configurable timer and a count register. The timer counts the number of phase edges (using the same configuration as for the position integrator) in a given time period. The edge count from the previous time period is available to the controller via the **QEI Velocity (QEISPEED)** register, while the edge count for the current time period is being accumulated in the **QEI Velocity Counter (QEICOUNT)** register. As soon as the current time period is complete, the total number of edges counted in that time period is made available in the **QEISPEED** register (overwriting the previous value), the **QEICOUNT** register is cleared, and counting commences on a new time period. The number of edges counted in a given time period is directly proportional to the velocity of the encoder.

Figure 29-3 on page 2012 shows how the TM4C129XKCZAD quadrature encoder converts the phase input signals into clock pulses, the direction signal, and how the velocity predivider operates (in Divide by 4 mode).

Figure 29-3. Quadrature Encoder and Velocity Predivider Operation

The period of the timer is configurable by specifying the load value for the timer in the **QEI Timer Load (QEILOAD)** register. When the timer reaches zero, an interrupt can be triggered, and the hardware reloads the timer with the **QEILOAD** value and continues to count down. At lower encoder speeds, a longer timer period is required to be able to capture enough edges to have a meaningful result. At higher encoder speeds, both a shorter timer period and/or the velocity predivider can be used.

The following equation converts the velocity counter value into an rpm value:

```
rpm = (clock * (2 ^ VELDIV) * SPEED * 60) ÷ (LOAD * ppr * edges)
```

where:

clock is the controller clock rate

`ppr` is the number of pulses per revolution of the physical encoder

edges is 2 or 4, based on the capture mode set in the **QEICTL** register (2 for CAPMODE clear and 4 for CAPMODE set)

For example, consider a motor running at 600 rpm. A 2048 pulse per revolution quadrature encoder is attached to the motor, producing 8192 phase edges per revolution. With a velocity predivider of $\div 1$ (VELDIV is clear) and clocking on both PhA and PhB edges, this results in 81,920 pulses per second (the motor turns 10 times per second). If the timer were clocked at 10,000 Hz, and the load value was 2,500 ($\frac{1}{4}$ of a second), it would count 20,480 pulses per update. Using the above equation:

$$\text{rpm} = (10000 * 1 * 20480 * 60) \div (2500 * 2048 * 4) = 600 \text{ rpm}$$

Now, consider that the motor is sped up to 3000 rpm. This results in 409,600 pulses per second, or 102,400 every $\frac{1}{4}$ of a second. Again, the above equation gives:

$$\text{rpm} = (10000 * 1 * 102400 * 60) \div (2500 * 2048 * 4) = 3000 \text{ rpm}$$

Care must be taken when evaluating this equation because intermediate values may exceed the capacity of a 32-bit integer. In the above examples, the clock is 10,000 and the divider is 2,500; both could be predivided by 100 (at compile time if they are constants) and therefore be 100 and 25. In fact, if they were compile-time constants, they could also be reduced to a simple multiply by 4, cancelled by the $\div 4$ for the edge-count factor.

Important: Reducing constant factors at compile time is the best way to control the intermediate values of this equation and reduce the processing requirement of computing this equation.

The division can be avoided by selecting a timer load value such that the divisor is a power of 2; a simple shift can therefore be done in place of the division. For encoders with a power of 2 pulses per revolution, the load value can be a power of 2. For other encoders, a load value must be selected such that the product is very close to a power of 2. For example, a 100 pulse-per-revolution encoder

could use a load value of 82, resulting in 32,800 as the divisor, which is 0.09% above 2^{14} . In this case a shift by 15 would be an adequate approximation of the divide in most cases. If absolute accuracy were required, the microcontroller's divide instruction could be used.

The QEI module can produce a controller interrupt on several events: phase error, direction change, reception of the index pulse, and expiration of the velocity timer. Standard masking, raw interrupt status, interrupt status, and interrupt clear capabilities are provided.

29.4 Initialization and Configuration

The following example shows how to configure the Quadrature Encoder module to read back an absolute position:

1. Enable the QEI clock using the **RCGCQEI** register in the System Control module (see page 415).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 398).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 31-4 on page 2068.
4. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the QEI signals to the appropriate pins (see page 816 and Table 31-5 on page 2085).
5. Configure the quadrature encoder to capture edges on both signals and maintain an absolute position by resetting on index pulses. A 1000-line encoder with four edges per line, results in 4000 pulses per revolution; therefore, set the maximum position to 3999 (0xF9F) as the count is zero-based.
 - Write the **QEICTL** register with the value of 0x0000.0018.
 - Write the **QEIMAXPOS** register with the value of 0x0000.0F9F.
6. Enable the quadrature encoder by setting bit 0 of the **QEICTL** register.
Note: Once the QEI module has been enabled by setting the **ENABLE** bit in the **QEICTL** register, it cannot be disabled. The only way to clear the **ENABLE** bit is to reset the module using the **Quadrature Encoder Interface Software Reset (SRQEI)** register.
7. Delay until the encoder position is required.
8. Read the encoder position by reading the **QEI Position (QEIPOS)** register value.

29.5 Register Map

Table 29-2 on page 2014 lists the QEI registers. The offset listed is a hexadecimal increment to the register's address, relative to the module's base address:

- QEI0: 0x4002.C000

Note that the QEI module clock must be enabled before the registers can be programmed (see page 415). There must be a delay of 3 system clocks after the QEI module clock is enabled before any QEI module registers are accessed.

29.6 Register Descriptions

The remainder of this section lists and describes the QEI registers, in numerical order by address offset.

Register 1: QEI Control (QEICTL), offset 0x000

This register contains the configuration of the QEI module. Separate enables are provided for the quadrature encoder and the velocity capture blocks; the quadrature encoder must be enabled in order to capture the velocity, but the velocity does not need to be captured in applications that do not need it. The phase signal interpretation, phase swap, Position Update mode, Position Reset mode, and velocity predivider are all set via this register.

0	The QEI inputs are not filtered.									
1	Enables the digital noise filter on the QEI input signals. Inputs must be stable for 3 consecutive clock edges before the edge detector is updated.									
12	STALLEN	RW	0	<p>Stall QEI</p> <table border="0"> <tr> <th>Value</th> <th>Description</th> </tr> <tr> <td>0</td> <td>The QEI module does not stall when the microcontroller is stopped by a debugger.</td> </tr> <tr> <td>1</td> <td>The QEI module stalls when the microcontroller is stopped by a debugger.</td> </tr> </table>	Value	Description	0	The QEI module does not stall when the microcontroller is stopped by a debugger.	1	The QEI module stalls when the microcontroller is stopped by a debugger.
Value	Description									
0	The QEI module does not stall when the microcontroller is stopped by a debugger.									
1	The QEI module stalls when the microcontroller is stopped by a debugger.									

Bit/Field	Name	Type	Reset	Description
11	INVI	RW	0	Invert Index Pulse Value Description 0 No effect. 1 Inverts the <code>IDX</code> input.
10	INVB	RW	0	Invert PhB Value Description 0 No effect. 1 Inverts the <code>PhBn</code> input.
9	INVA	RW	0	Invert PhA Value Description 0 No effect. 1 Inverts the <code>PhAn</code> input.
8:6	VELDIV	RW	0x0	Predivide Velocity This field defines the predivider of the input quadrature pulses before being applied to the QEICOUNT accumulator. Value Predivider 0x0 ÷1 0x1 ÷2 0x2 ÷4 0x3 ÷8 0x4 ÷16 0x5 ÷32 0x6 ÷64 0x7 ÷128
5	VELEN	RW	0	Capture Velocity Value Description 0 No effect. 1 Enables capture of the velocity of the quadrature encoder.
4	RESMODE	RW	0	Reset Mode Value Description 0 The position counter is reset when it reaches the maximum as defined by the <code>MAXPOS</code> field in the QEIMAXPOS register. 1 The position counter is reset when the index pulse is captured.

Bit/Field	Name	Type	Reset	Description						
3	CAPMODE	RW	0	<p>Capture Mode</p> <p>Note: When SIGMODE=1, the CAPMODE setting is not applicable and is reserved.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>Only the PhA edges are counted.</td></tr> <tr> <td>1</td><td>The PhA and PhB edges are counted, providing twice the positional resolution but half the range.</td></tr> </tbody> </table>	Value	Description	0	Only the PhA edges are counted.	1	The PhA and PhB edges are counted, providing twice the positional resolution but half the range.
Value	Description									
0	Only the PhA edges are counted.									
1	The PhA and PhB edges are counted, providing twice the positional resolution but half the range.									
2	SIGMODE	RW	0	<p>Signal Mode</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The internal PhA and PhB signals operate as quadrature phase signals.</td></tr> <tr> <td>1</td><td>The internal PhA input operates as the clock (CLK) signal and the internal PhB input operates as the direction (DIR) signal.</td></tr> </tbody> </table>	Value	Description	0	The internal PhA and PhB signals operate as quadrature phase signals.	1	The internal PhA input operates as the clock (CLK) signal and the internal PhB input operates as the direction (DIR) signal.
Value	Description									
0	The internal PhA and PhB signals operate as quadrature phase signals.									
1	The internal PhA input operates as the clock (CLK) signal and the internal PhB input operates as the direction (DIR) signal.									
1	SWAP	RW	0	<p>Swap Signals</p> <p>Note if the INVA or INVb bit are set, the inversion of the signals occur prior to the swap.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No effect.</td></tr> <tr> <td>1</td><td>Swaps the PhAn and PhBn signals.</td></tr> </tbody> </table>	Value	Description	0	No effect.	1	Swaps the PhAn and PhBn signals.
Value	Description									
0	No effect.									
1	Swaps the PhAn and PhBn signals.									
0	ENABLE	RW	0	<p>Enable QEI</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>No effect.</td></tr> <tr> <td>1</td><td>Enables the quadrature encoder module.</td></tr> </tbody> </table> <p>Note: Once the QEI module has been enabled by setting the ENABLE bit, it cannot be disabled. The only way to clear the ENABLE bit is to reset the module using the Quadrature Encoder Interface Software Reset (SRQEI) register.</p>	Value	Description	0	No effect.	1	Enables the quadrature encoder module.
Value	Description									
0	No effect.									
1	Enables the quadrature encoder module.									

Register 2: QEI Status (QEISTAT), offset 0x004

This register provides status about the operation of the QEI module.

QEI Status (QEISTAT)

QEI0 base: 0x4002.C000

Offset 0x004

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	DIRECTION	RO	0	<p>Direction of Rotation Indicates the direction the encoder is rotating.</p> <p>Value Description</p> <p>0 The encoder is rotating forward.</p> <p>1 The encoder is rotating in reverse.</p>
0	ERROR	RO	0	<p>Error Detected</p> <p>Value Description</p> <p>0 No error.</p> <p>1 An error was detected in the gray code sequence (that is, both signals changing at the same time).</p>

Register 3: QEI Position (QEIPOS), offset 0x008

This register contains the current value of the position integrator. The value is updated by the status of the QEI phase inputs and can be set to a specific value by writing to it.

QEI Position (QEIPOS)

QEI0 base: 0x4002.C000

Offset 0x008

Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0	POSITION	RW	0x0000.0000	Current Position Integrator Value The current value of the position integrator.
------	----------	----	-------------	--

Register 4: QEI Maximum Position (QEIMAXPOS), offset 0x00C

This register contains the maximum value of the position integrator. When moving forward, the position register resets to zero when it increments past this value. When moving in reverse, the position register resets to this value when it decrements from zero.

QEI Maximum Position (QEIMAXPOS)

QEI0 base: 0x4002.C000

Offset 0x00C

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	MAXPOS	RW	0x0000.0000	Maximum Position Integrator Value The maximum value of the position integrator.

Register 5: QEI Timer Load (QEILOAD), offset 0x010

This register contains the load value for the velocity timer. Because this value is loaded into the timer on the clock cycle after the timer is zero, this value should be one less than the number of clocks in the desired period. So, for example, to have 2000 decimal clocks per timer period, this register should contain 1999 decimal.

QEI Timer Load (QEILOAD)

QEI0 base: 0x4002.C000

Offset 0x010

Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	LOAD	RW	0x0000.0000	Velocity Timer Load Value The load value for the velocity timer.

Register 6: QEI Timer (QEITIME), offset 0x014

This register contains the current value of the velocity timer. This counter does not increment when the VELEN bit in the **QEICTL** register is clear.

QEI Timer (QEITIME)

QEI0 base: 0x4002.C000

Offset 0x014

Type RO, reset 0x0000.0000

Bit/Field

Name

Type

Reset

Description

31:0 TIME RO 0x0000.0000 Velocity Timer Current Value

The current value of the velocity timer.

Register 7: QEI Velocity Counter (QEICOUNT), offset 0x018

This register contains the running count of velocity pulses for the current time period. Because this count is a running total, the time period to which it applies cannot be known with precision (that is, a read of this register does not necessarily correspond to the time returned by the **QEITIME** register because there is a small window of time between the two reads, during which either value may have changed). The **QEISPEED** register should be used to determine the actual encoder velocity; this register is provided for information purposes only. This counter does not increment when the **VELEN** bit in the **QEICTL** register is clear.

QEI Velocity Counter (QEICOUNT)

QEI0 base: 0x4002.C000

Offset 0x018

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	COUNT	RO	0x0000.0000	Velocity Pulse Count The running total of encoder pulses during this velocity timer period.

Register 8: QEI Velocity (QEISPEED), offset 0x01C

This register contains the most recently measured velocity of the quadrature encoder. This value corresponds to the number of velocity pulses counted in the previous velocity timer period. This register does not update when the VELEN bit in the **QEICTL** register is clear.

QEI Velocity (QEISPEED)

QEIO base: 0x4002.C000

Offset 0x01C

Type RO, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:0 SPEED RO 0x0000.0000 Velocity

The measured speed of the quadrature encoder in pulses per period.

Register 9: QEI Interrupt Enable (QEIINTEN), offset 0x020

This register contains enables for each of the QEI module interrupts. An interrupt is asserted to the interrupt controller if the corresponding bit in this register is set.

QEI Interrupt Enable (QEIINTEN)

QEI0 base: 0x4002.C000

Offset 0x020

Type RW, reset 0x0000.0000

Bit/Field Name Type Reset Description

31:4 reserved RO 0x0000.000 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

3 INTERROR RW 0 Phase Error Interrupt Enable

Note: The INTERROR bit is only applicable when the QEI is operating in quadrature phase mode (**SIGMODE=0**) and should be masked when **SIGMODE =1**.

Value Description

0 The INTERROR interrupt is suppressed and not sent to the interrupt controller.

1 An interrupt is sent to the interrupt controller when the INTERROR bit in the **QEIRIS** register is set.

2 INTDIR RW 0 Direction Change Interrupt Enable

Value Description

0 The INTDIR interrupt is suppressed and not sent to the interrupt controller.

1 An interrupt is sent to the interrupt controller when the INTDIR bit in the **QEIRIS** register is set.

1 INTTIMER RW 0 Timer Expires Interrupt Enable

Value Description

0 The INTTIMER interrupt is suppressed and not sent to the interrupt controller.

1 An interrupt is sent to the interrupt controller when the INTTIMER bit in the **QEIRIS** register is set.

Bit/Field	Name	Type	Reset	Description
0	INTINDEX	RW	0	Index Pulse Detected Interrupt Enable
Value Description				
		0		The INTINDEX interrupt is suppressed and not sent to the interrupt controller.
		1		An interrupt is sent to the interrupt controller when the INTINDEX bit in the QEIRIS register is set.

Register 10: QEI Raw Interrupt Status (QEIRIS), offset 0x024

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (configured through the **QEINTEN** register). If a bit is set, the latched event has occurred; if a bit is clear, the event in question has not occurred.

QEI Raw Interrupt Status (QEIRIS)

QEIO base: 0x4002.C000

QEI0 base: 0x0000000000000000
Offset 0x024

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:4	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
3	INTERROR	RO	0	<p>Phase Error Detected</p> <p>Note: The INTERROR bit is only applicable when the QEI is operating in quadrature phase mode ($SIGMODE=0$).</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>An interrupt has not occurred.</td></tr> <tr> <td>1</td><td>A phase error has been detected.</td></tr> </tbody> </table> <p>This bit is cleared by writing a 1 to the INTERROR bit in the QEIIISC register.</p>	Value	Description	0	An interrupt has not occurred.	1	A phase error has been detected.
Value	Description									
0	An interrupt has not occurred.									
1	A phase error has been detected.									
2	INTDIR	RO	0	<p>Direction Change Detected</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>An interrupt has not occurred.</td></tr> <tr> <td>1</td><td>The rotation direction has changed</td></tr> </tbody> </table> <p>This bit is cleared by writing a 1 to the INTDIR bit in the QEIIISC register.</p>	Value	Description	0	An interrupt has not occurred.	1	The rotation direction has changed
Value	Description									
0	An interrupt has not occurred.									
1	The rotation direction has changed									
1	INTTIMER	RO	0	<p>Velocity Timer Expired</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>An interrupt has not occurred.</td></tr> <tr> <td>1</td><td>The velocity timer has expired.</td></tr> </tbody> </table> <p>This bit is cleared by writing a 1 to the INTTIMER bit in the QEIIISC register.</p>	Value	Description	0	An interrupt has not occurred.	1	The velocity timer has expired.
Value	Description									
0	An interrupt has not occurred.									
1	The velocity timer has expired.									

Bit/Field	Name	Type	Reset	Description
0	INTINDEX	RO	0	Index Pulse Asserted
				Value Description
			0	An interrupt has not occurred.
			1	The index pulse has occurred.
				This bit is cleared by writing a 1 to the INTINDEX bit in the QEIIISC register.

Register 11: QEI Interrupt Status and Clear (QEIIISC), offset 0x028

This register provides the current set of interrupt sources that are asserted to the controller. If a bit is set, the latched event has occurred and is enabled to generate an interrupt; if a bit is clear the event in question has not occurred or is not enabled to generate an interrupt. This register is RW1C; writing a 1 to a bit position clears the bit and the corresponding interrupt reason.

QEI Interrupt Status and Clear (QEIIISC)

QEIO base: 0x4002.C000

Offset 0x028

Type RW1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x0000.0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	INTERROR	RW1C	0	Phase Error Interrupt
		Value	Description	
		0	No interrupt has occurred or the interrupt is masked.	
		1	The INTERROR bits in the QEIRIS register and the QEINTEN registers are set, providing an interrupt to the interrupt controller.	
		This bit is cleared by writing a 1. Clearing this bit also clears the INTERROR bit in the QEIRIS register.		
2	INTDIR	RW1C	0	Direction Change Interrupt
		Value	Description	
		0	No interrupt has occurred or the interrupt is masked.	
		1	The INTDIR bits in the QEIRIS register and the QEINTEN registers are set, providing an interrupt to the interrupt controller.	
		This bit is cleared by writing a 1. Clearing this bit also clears the INTDIR bit in the QEIRIS register.		
1	INTTIMER	RW1C	0	Velocity Timer Expired Interrupt
		Value	Description	
		0	No interrupt has occurred or the interrupt is masked.	
		1	The INTTIMER bits in the QEIRIS register and the QEINTEN registers are set, providing an interrupt to the interrupt controller.	
		This bit is cleared by writing a 1. Clearing this bit also clears the INTTIMER bit in the QEIRIS register.		

Bit/Field	Name	Type	Reset	Description
0	INTINDEX	RW1C	0	Index Pulse Interrupt
Value Description				
		0	No interrupt has occurred or the interrupt is masked.	
		1	The INTINDEX bits in the QEIRIS register and the QEINTEN registers are set, providing an interrupt to the interrupt controller.	
This bit is cleared by writing a 1. Clearing this bit also clears the INTINDEX bit in the QEIRIS register.				

30 Pin Diagram

The TM4C129XKCZAD microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 31-5 on page 2085.

Figure 30-1. 212-Ball BGA Package Pin Diagram (Top View)

31 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. Use the **GPIOAMSEL** register (see page 815) to select analog mode. For a GPIO pin to be used for an alternate digital function, the corresponding bit in the **GPIOAFSEL** register (see page 799) must be set. Further pin muxing options are provided through the **PMCx** bit field in the **GPIOPCTL** register (see page 816), which selects one of several available peripheral functions for that GPIO.

Important: All GPIO pins are configured as GPIOs by default with the exception of the pins shown in the table below. A Power-On-Reset (**POR**) or asserting **RST** puts the pins back to their default state.

Table 31-1. GPIO Pins With Default Alternate Functions

GPIO Pin	Default State	GPIOAFSEL Bit	GPIOPCTL PMCx Bit Field
PA[1:0]	UART0	0	0x1
PA[5:2]	SSI0	0	0x1
PB[3:2]	I ² C0	0	0x1
PC[3:0]	JTAG/SWD	1	0x3

Table 31-2 on page 2033 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate analog and digital function is listed for each pin.

Table 31-3 on page 2052 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the **PMCx** bit field in the **GPIOPCTL** register.

Table 31-4 on page 2068 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 31-5 on page 2085 lists the GPIO pins and their analog and digital alternate functions. The **AINx** analog signals are not 5-V tolerant and go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding **AMSEL** bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 3.3-V tolerant and are connected directly to their circuitry (**C0-**, **C0+**, **C1-**, **C1+**, **C2-**, **C2+**, **USB0VBUS**, **USB0ID**). These signals are configured by clearing the **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register. The digital signals are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GPIODEN** registers and configuring the **PMCx** bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Table 31-6 on page 2090 lists the signals based on number of possible pin assignments. This table can be used to plan how to configure the pins for a particular functionality. Application Note AN01274 Configuring Tiva™ C Series Microcontrollers with Pin Multiplexing provides an overview of the pin muxing implementation, an explanation of how a system designer defines a pin configuration, and examples of the pin configuration process.

Note: All digital inputs are Schmitt triggered.

31.1 Signals by Pin Number

Table 31-2. Signals by Pin Number

Pin Number	Pin Name	Pin Type	Buffer Type	Description
A1	GND	-	Power	Ground reference for logic and I/O pins.
A2	GND	-	Power	Ground reference for logic and I/O pins.
A4	PD4	I/O	TTL	GPIO port D bit 4.
	AIN7	I	Analog	Analog-to-digital converter input 7.
	SSI1XDAT2	I/O	TTL	SSI Module 1 Bi-directional Data Pin 2.
	T3CCP0	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 0.
	U2Rx	I	TTL	UART module 2 receive.
A5	PE4	I/O	TTL	GPIO port E bit 4.
	AIN9	I	Analog	Analog-to-digital converter input 9.
	SSI1XDAT0	I/O	TTL	SSI Module 1 Bi-directional Data Pin 0 (SSI1TX in Legacy SSI Mode).
	U1RI	I	TTL	UART module 1 Ring Indicator modem status input signal.
A7	PE6	I/O	TTL	GPIO port E bit 6.
	AIN20	I	Analog	Analog-to-digital converter input 20.
	I2C9SCL	I/O	OD	I ² C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	U0CTS	I	TTL	UART module 0 Clear To Send modem flow control input signal.
A8	PP7	I/O	TTL	GPIO port P bit 7.
	AIN22	I	Analog	Analog-to-digital converter input 22.
	OWIRE	I/O	TTL	1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled.
A10	PN4	I/O	TTL	GPIO port N bit 4.
	EPI0S34	I/O	TTL	EPI module 0 signal 34.
	I2C2SDA	I/O	OD	I ² C module 2 data.
	U1DTR	O	TTL	UART module 1 Data Terminal Ready modem status input signal.
	U3RTS	O	TTL	UART module 3 Request to Send modem flow control output line.
A11	PN2	I/O	TTL	GPIO port N bit 2.
	EPI0S29	I/O	TTL	EPI module 0 signal 29.
	U1DCD	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
	U2RTS	O	TTL	UART module 2 Request to Send modem flow control output line.
A13	PQ4	I/O	TTL	GPIO port Q bit 4.
	DIVSCLK	O	TTL	An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock.
	U1Rx	I	TTL	UART module 1 receive.
A14	PS3	I/O	TTL	GPIO port S bit 3.
	LCDDATA23	O	TTL	LCD Data Pin 23 output.
	M0FAULT3	I	TTL	Motion Control Module 0 PWM Fault 3.
	T3CCP1	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 1.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
A16	PB0	I/O	TTL	GPIO port B bit 0.
	CAN1Rx	I	TTL	CAN module 1 receive.
	I2C5SCL	I/O	OD	I ² C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	T4CCP0	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 0.
	U1Rx	I	TTL	UART module 1 receive.
	USB0ID	I	Analog	This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side).
A17	PB2	I/O	TTL	GPIO port B bit 2.
	EN0MDC	O	TTL	Ethernet 0 Management Data Clock.
	EPI0S27	I/O	TTL	EPI module 0 signal 27.
	I2C0SCL	I/O	OD	I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	T5CCP0	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 0.
	USB0STP	O	TTL	Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.
A18	GND	-	Power	Ground reference for logic and I/O pins.
A19	GND	-	Power	Ground reference for logic and I/O pins.
B1	GND	-	Power	Ground reference for logic and I/O pins.
B2	PD7	I/O	TTL	GPIO port D bit 7.
	AIN4	I	Analog	Analog-to-digital converter input 4.
	NMI	I	TTL	Non-maskable interrupt.
	SSI2XDAT2	I/O	TTL	SSI Module 2 Bi-directional Data Pin 2.
	T4CCP1	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 1.
	U2CTS	I	TTL	UART module 2 Clear To Send modem flow control input signal.
	USB0PFLT	I	TTL	Optionally used in Host mode by an external power source to indicate an error state by that power source.
B3	PD6	I/O	TTL	GPIO port D bit 6.
	AIN5	I	Analog	Analog-to-digital converter input 5.
	SSI2XDAT3	I/O	TTL	SSI Module 2 Bi-directional Data Pin 3.
	T4CCP0	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 0.
	U2RTS	O	TTL	UART module 2 Request to Send modem flow control output line.
	USB0EPEN	O	TTL	Optionally used in Host mode to control an external power source to supply power to the USB bus.
B4	PD5	I/O	TTL	GPIO port D bit 5.
	AIN6	I	Analog	Analog-to-digital converter input 6.
	SSI1XDAT3	I/O	TTL	SSI Module 1 Bi-directional Data Pin 3.
	T3CCP1	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 1.
	U2Tx	O	TTL	UART module 2 transmit.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
B5	PE5	I/O	TTL	GPIO port E bit 5.
	AIN8	I	Analog	Analog-to-digital converter input 8.
	SSI1XDAT1	I/O	TTL	SSI Module 1 Bi-directional Data Pin 1 (SSI1RX in Legacy SSI Mode).
B6	PB5	I/O	TTL	GPIO port B bit 5.
	AIN11	I	Analog	Analog-to-digital converter input 11.
	I2C5SDA	I/O	OD	I ² C module 5 data.
	SSI1Clk	I/O	TTL	SSI module 1 clock.
	U0RTS	O	TTL	UART module 0 Request to Send modem flow control output signal.
B7	PE7	I/O	TTL	GPIO port E bit 7.
	AIN21	I	Analog	Analog-to-digital converter input 21.
	I2C9SDA	I/O	OD	I ² C module 9 data.
	NMI	I	TTL	Non-maskable interrupt.
	U0RTS	O	TTL	UART module 0 Request to Send modem flow control output signal.
B8	PP6	I/O	TTL	GPIO port P bit 6.
	AIN23	I	Analog	Analog-to-digital converter input 23.
	I2C2SDA	I/O	OD	I ² C module 2 data.
	U1DCD	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
B9	PN5	I/O	TTL	GPIO port N bit 5.
	EPI0S35	I/O	TTL	EPI module 0 signal 35.
	I2C2SCL	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	U1RI	I	TTL	UART module 1 Ring Indicator modem status input signal.
	U3CTS	I	TTL	UART module 3 Clear To Send modem flow control input signal.
B10	PN3	I/O	TTL	GPIO port N bit 3.
	EPI0S30	I/O	TTL	EPI module 0 signal 30.
	U1DSR	I	TTL	UART module 1 Data Set Ready modem output control line.
	U2CTS	I	TTL	UART module 2 Clear To Send modem flow control input signal.
B11	PN1	I/O	TTL	GPIO port N bit 1.
	U1CTS	I	TTL	UART module 1 Clear To Send modem flow control input signal.
B12	PP5	I/O	TTL	GPIO port P bit 5.
	I2C2SCL	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	OWALT	I/O	TTL	1-Wire Optional 2nd signal to be used as output.
	U3CTS	I	TTL	UART module 3 Clear To Send modem flow control input signal.
	USB0D6	I/O	TTL	USB data 6.
B13	PP2	I/O	TTL	GPIO port P bit 2.
	EPI0S29	I/O	TTL	EPI module 0 signal 29.
	U0DTR	O	TTL	UART module 0 Data Terminal Ready modem status input signal.
	USB0NXT	O	TTL	Asserted by the external PHY to throttle all data types.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
B14	PS2	I/O	TTL	GPIO port S bit 2.
	LCDDATA22	O	TTL	LCD Data Pin 22 output.
	M0FAULT2	I	TTL	Motion Control Module 0 PWM Fault 2.
	T3CCP0	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 0.
	U1DSR	I	TTL	UART module 1 Data Set Ready modem output control line.
B15	PC0	I/O	TTL	GPIO port C bit 0.
	SWCLK	I	TTL	JTAG/SWD CLK.
	TCK	I	TTL	JTAG/SWD CLK.
B16	PB1	I/O	TTL	GPIO port B bit 1.
	CAN1Tx	O	TTL	CAN module 1 transmit.
	I2C5SDA	I/O	OD	I ² C module 5 data.
	T4CCP1	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 1.
	U1Tx	O	TTL	UART module 1 transmit.
	USB0VBUS	I/O	Analog	This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.
B17	PB3	I/O	TTL	GPIO port B bit 3.
	EN0MDIO	I/O	TTL	Ethernet 0 Management Data Input/Output signal.
	EPI0S28	I/O	TTL	EPI module 0 signal 28.
	I2C0SDA	I/O	OD	I ² C module 0 data.
	T5CCP1	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 1.
	USB0CLK	O	TTL	60-MHz clock to the external PHY.
B18	PL7	I/O	TTL	GPIO port L bit 7.
	T1CCP1	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.
	USB0DM	I/O	Analog	Bidirectional differential data pin (D- per USB specification) for USB0.
B19	GND	-	Power	Ground reference for logic and I/O pins.
C1	PD1	I/O	TTL	GPIO port D bit 1.
	AIN14	I	Analog	Analog-to-digital converter input 14.
	C1o	O	TTL	Analog comparator 1 output.
	I2C7SDA	I/O	OD	I ² C module 7 data.
	SSI2XDAT0	I/O	TTL	SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode).
	T0CCP1	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
C2	PD0	I/O	TTL	GPIO port D bit 0.
	AIN15	I	Analog	Analog-to-digital converter input 15.
	C0o	O	TTL	Analog comparator 0 output.
	I2C7SCL	I/O	OD	I ² C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	SSI2XDAT1	I/O	TTL	SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode).
	T0CCP0	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 0.
C5	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
C6	PB4	I/O	TTL	GPIO port B bit 4.
	AIN10	I	Analog	Analog-to-digital converter input 10.
	I2C5SCL	I/O	OD	I ² C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	SSI1FSS	I/O	TTL	SSI module 1 frame signal.
	U0CTS	I	TTL	UART module 0 Clear To Send modem flow control input signal.
C8	PJ0	I/O	TTL	GPIO port J bit 0.
	EN0PPS	O	TTL	Ethernet 0 Pulse-Per-Second (PPS) Output.
	U3Rx	I	TTL	UART module 3 receive.
C10	PN0	I/O	TTL	GPIO port N bit 0.
	U1RTS	O	TTL	UART module 1 Request to Send modem flow control output line.
C12	PP3	I/O	TTL	GPIO port P bit 3.
	EPI0S30	I/O	TTL	EPI module 0 signal 30.
	RTCCLK	O	TTL	Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset.
	U0DCD	I	TTL	UART module 0 Data Carrier Detect modem status input signal.
	U1CTS	I	TTL	UART module 1 Clear To Send modem flow control input signal.
	USB0DIR	O	TTL	Indicates that the external PHY is able to accept data from the USB controller.
C14	PC3	I/O	TTL	GPIO port C bit 3.
	SWO	O	TTL	JTAG TDO and SWO.
	TDO	O	TTL	JTAG TDO and SWO.
C15	PC1	I/O	TTL	GPIO port C bit 1.
	SWDIO	I/O	TTL	JTAG TMS and SWDIO.
	TMS	I	TTL	JTAG TMS and SWDIO.
C18	PL6	I/O	TTL	GPIO port L bit 6.
	T1CCP0	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.
	USB0DP	I/O	Analog	Bidirectional differential data pin (D+ per USB specification) for USB0.
D1	PD3	I/O	TTL	GPIO port D bit 3.
	AIN12	I	Analog	Analog-to-digital converter input 12.
	I2C8SDA	I/O	OD	I ² C module 8 data.
	SSI2Clk	I/O	TTL	SSI module 2 clock.
	T1CCP1	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.
D2	PD2	I/O	TTL	GPIO port D bit 2.
	AIN13	I	Analog	Analog-to-digital converter input 13.
	C2o	O	TTL	Analog comparator 2 output.
	I2C8SCL	I/O	OD	I ² C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	SSI2FSS	I/O	TTL	SSI module 2 frame signal.
	T1CCP0	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
D6	PP0	I/O	TTL	GPIO port P bit 0.
	C2+	I	Analog	Analog comparator 2 positive input.
	EN0INTRN	I	TTL	Ethernet 0 Interrupt from the Ethernet PHY.
	SSI3XDAT2	I/O	TTL	SSI Module 3 Bi-directional Data Pin 2.
	T6CCP0	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 0.
	U6Rx	I	TTL	UART module 6 receive.
D7	PP1	I/O	TTL	GPIO port P bit 1.
	C2-	I	Analog	Analog comparator 2 negative input.
	SSI3XDAT3	I/O	TTL	SSI Module 3 Bi-directional Data Pin 3.
	T6CCP1	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 1.
	U6Tx	O	TTL	UART module 6 transmit.
D8	PP4	I/O	TTL	GPIO port P bit 4.
	OWIRE	I/O	TTL	1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled.
	U0DSR	I	TTL	UART module 0 Data Set Ready modem output control line.
	U3RTS	O	TTL	UART module 3 Request to Send modem flow control output line.
	USB0D7	I/O	TTL	USB data 7.
D12	PS0	I/O	TTL	GPIO port S bit 0.
	LCDDATA20	O	TTL	LCD Data Pin 20 output.
	M0FAULT0	I	TTL	Motion Control Module 0 PWM Fault 0.
	T2CCP0	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 0.
D13	PS1	I/O	TTL	GPIO port S bit 1.
	LCDDATA21	O	TTL	LCD Data Pin 21 output.
	M0FAULT1	I	TTL	Motion Control Module 0 PWM Fault 1.
	T2CCP1	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 1.
D14	PC2	I/O	TTL	GPIO port C bit 2.
	TDI	I	TTL	JTAG TDI.
D18	GNDX2	-	Power	GND for the MOSC. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.
D19	OSC1	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
E2	PQ1	I/O	TTL	GPIO port Q bit 1.
	EPI0S21	I/O	TTL	EPI module 0 signal 21.
	SSI3FSS	I/O	TTL	SSI module 3 frame signal.
	T6CCP1	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 1.
E3	PQ0	I/O	TTL	GPIO port Q bit 0.
	EPI0S20	I/O	TTL	EPI module 0 signal 20.
	SSI3Clk	I/O	TTL	SSI module 3 clock.
	T6CCP0	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 0.
E7	PJ1	I/O	TTL	GPIO port J bit 1.
	U3Tx	O	TTL	UART module 3 transmit.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
E10	VDDC	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 32-15 on page 2112 .
E13	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
E17	PJ5	I/O	TTL	GPIO port J bit 5.
	LCDDATA17	O	TTL	LCD Data Pin 17 output.
	U3CTS	I	TTL	UART module 3 Clear To Send modem flow control input signal.
E18	PT2	I/O	TTL	GPIO port T bit 2.
	CAN1Rx	I	TTL	CAN module 1 receive.
	LCDDATA18	O	TTL	LCD Data Pin 18 output.
	T7CCP0	I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 0.
E19	OSC0	I	Analog	Main oscillator crystal input or an external clock reference input.
F1	PB7	I/O	TTL	GPIO port B bit 7.
	I2C6SDA	I/O	OD	I ² C module 6 data.
	T6CCP1	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 1.
F2	PB6	I/O	TTL	GPIO port B bit 6.
	I2C6SCL	I/O	OD	I ² C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	T6CCP0	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 0.
F3	VDDA	-	Power	The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation.
F4	VREFA+	-	Analog	A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value . The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 32-44 on page 2134.
F10	GND	-	Power	Ground reference for logic and I/O pins.
F16	PJ3	I/O	TTL	GPIO port J bit 3.
	LCDDATA15	I/O	TTL	LCD Data Pin 15 input/output.
	U2CTS	I	TTL	UART module 2 Clear To Send modem flow control input signal.
F17	PT3	I/O	TTL	GPIO port T bit 3.
	CAN1Tx	O	TTL	CAN module 1 transmit.
	LCDDATA19	O	TTL	LCD Data Pin 19 output.
	T7CCP1	I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 1.
F18	PJ4	I/O	TTL	GPIO port J bit 4.
	LCDDATA16	O	TTL	LCD Data Pin 16 output.
	U3RTS	O	TTL	UART module 3 Request to Send modem flow control output line.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
G1	PE2	I/O	TTL	GPIO port E bit 2.
	AIN1	I	Analog	Analog-to-digital converter input 1.
	U1DCD	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
G2	PE3	I/O	TTL	GPIO port E bit 3.
	AIN0	I	Analog	Analog-to-digital converter input 0.
	OWIRE	I/O	TTL	1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled.
	U1DTR	O	TTL	UART module 1 Data Terminal Ready modem status input signal.
G4	GNDA	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
G5	VREFA-	-	Analog	A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 32-44 on page 2134.
G10	VDD	-	Power	Positive supply for I/O and some logic.
G15	PM5	I/O	TTL	GPIO port M bit 5.
	T4CCP1	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 1.
	TMPR2	I/O	TTL	Tamper signal 2.
	U0DCD	I	TTL	UART module 0 Data Carrier Detect modem status input signal.
G16	PL0	I/O	TTL	GPIO port L bit 0.
	EPI0S16	I/O	TTL	EPI module 0 signal 16.
	I2C2SDA	I/O	OD	I ² C module 2 data.
	M0FAULT3	I	TTL	Motion Control Module 0 PWM Fault 3.
	USB0D0	I/O	TTL	USB data 0.
G18	PL2	I/O	TTL	GPIO port L bit 2.
	C0o	O	TTL	Analog comparator 0 output.
	EPI0S18	I/O	TTL	EPI module 0 signal 18.
	PhB0	I	TTL	QEI module 0 phase B.
	USB0D2	I/O	TTL	USB data 2.
G19	PL5	I/O	TTL	GPIO port L bit 5.
	EPI0S33	I/O	TTL	EPI module 0 signal 33.
	T0CCP1	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
	USB0D5	I/O	TTL	USB data 5.
H2	PE1	I/O	TTL	GPIO port E bit 1.
	AIN2	I	Analog	Analog-to-digital converter input 2.
	U1DSR	I	TTL	UART module 1 Data Set Ready modem output control line.
H3	PE0	I/O	TTL	GPIO port E bit 0.
	AIN3	I	Analog	Analog-to-digital converter input 3.
	U1RTS	O	TTL	UART module 1 Request to Send modem flow control output line.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
H4	PQ2	I/O	TTL	GPIO port Q bit 2.
	EPI0S22	I/O	TTL	EPI module 0 signal 22.
	SSI3XDATA0	I/O	TTL	SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode).
	T7CCP0	I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 0.
H9	VDD	-	Power	Positive supply for I/O and some logic.
H10	GND	-	Power	Ground reference for logic and I/O pins.
H11	GND	-	Power	Ground reference for logic and I/O pins.
H12	GND	-	Power	Ground reference for logic and I/O pins.
H16	VDDC	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 32-15 on page 2112 .
H17	PJ2	I/O	TTL	GPIO port J bit 2.
	LCDDATA14	I/O	TTL	LCD Data Pin 14 input/output.
	U2RTS	O	TTL	UART module 2 Request to Send modem flow control output line.
H18	PL4	I/O	TTL	GPIO port L bit 4.
	EPI0S26	I/O	TTL	EPI module 0 signal 26.
	T0CCP0	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 0.
	USB0D4	I/O	TTL	USB data 4.
H19	PL1	I/O	TTL	GPIO port L bit 1.
	EPI0S17	I/O	TTL	EPI module 0 signal 17.
	I2C2SCL	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	PhA0	I	TTL	QEI module 0 phase A.
	USB0D1	I/O	TTL	USB data 1.
J1	PK0	I/O	TTL	GPIO port K bit 0.
	AIN16	I	Analog	Analog-to-digital converter input 16.
	EPI0S0	I/O	TTL	EPI module 0 signal 0.
	U4Rx	I	TTL	UART module 4 receive.
J2	PK1	I/O	TTL	GPIO port K bit 1.
	AIN17	I	Analog	Analog-to-digital converter input 17.
	EPI0S1	I/O	TTL	EPI module 0 signal 1.
	U4Tx	O	TTL	UART module 4 transmit.
J8	VDD	-	Power	Positive supply for I/O and some logic.
J9	VDD	-	Power	Positive supply for I/O and some logic.
J10	VDD	-	Power	Positive supply for I/O and some logic.
J11	GND	-	Power	Ground reference for logic and I/O pins.
J12	GND	-	Power	Ground reference for logic and I/O pins.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
J18	PL3	I/O	TTL	GPIO port L bit 3.
	C1o	O	TTL	Analog comparator 1 output.
	EPI0S19	I/O	TTL	EPI module 0 signal 19.
	IDX0	I	TTL	QEI module 0 index.
	USB0D3	I/O	TTL	USB data 3.
K1	PK2	I/O	TTL	GPIO port K bit 2.
	AIN18	I	Analog	Analog-to-digital converter input 18.
	EPI0S2	I/O	TTL	EPI module 0 signal 2.
	U4RTS	O	TTL	UART module 4 Request to Send modem flow control output line.
K2	PK3	I/O	TTL	GPIO port K bit 3.
	AIN19	I	Analog	Analog-to-digital converter input 19.
	EPI0S3	I/O	TTL	EPI module 0 signal 3.
	U4CTS	I	TTL	UART module 4 Clear To Send modem flow control input signal.
K3	PC7	I/O	TTL	GPIO port C bit 7.
	C0-	I	Analog	Analog comparator 0 negative input.
	EPI0S4	I/O	TTL	EPI module 0 signal 4.
	U5Tx	O	TTL	UART module 5 transmit.
K5	PJ7	I/O	TTL	GPIO port J bit 7.
	U4CTS	I	TTL	UART module 4 Clear To Send modem flow control input signal.
K6	GND	-	Power	Ground reference for logic and I/O pins.
K7	VDD	-	Power	Positive supply for I/O and some logic.
K8	VDD	-	Power	Positive supply for I/O and some logic.
K9	GND	-	Power	Ground reference for logic and I/O pins.
K10	GND	-	Power	Ground reference for logic and I/O pins.
K11	VDD	-	Power	Positive supply for I/O and some logic.
K12	VDD	-	Power	Positive supply for I/O and some logic.
K13	GND	-	Power	Ground reference for logic and I/O pins.
K14	GND	-	Power	Ground reference for logic and I/O pins.
K15	PG5	I/O	TTL	GPIO port G bit 5.
	EN0TXD1	O	TTL	Ethernet 0 Transmit Data 1.
	I2C3SDA	I/O	OD	I ² C module 3 data.
	OWALT	I/O	TTL	1-Wire Optional 2nd signal to be used as output.
	SSI2XDAT0	I/O	TTL	SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode).
	U0RTS	O	TTL	UART module 0 Request to Send modem flow control output signal.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
K17	PG4	I/O	TTL	GPIO port G bit 4.
	EN0TXD0	O	TTL	Ethernet 0 Transmit Data 0.
	I2C3SCL	I/O	OD	I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	OWIRE	I/O	TTL	1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled.
	SSI2XDAT1	I/O	TTL	SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode).
	U0CTS	I	TTL	UART module 0 Clear To Send modem flow control input signal.
K18	PM0	I/O	TTL	GPIO port M bit 0.
	EPI0S15	I/O	TTL	EPI module 0 signal 15.
	T2CCP0	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 0.
K19	PM1	I/O	TTL	GPIO port M bit 1.
	EPI0S14	I/O	TTL	EPI module 0 signal 14.
	T2CCP1	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 1.
L2	PC6	I/O	TTL	GPIO port C bit 6.
	C0+	I	Analog	Analog comparator 0 positive input.
	EPI0S5	I/O	TTL	EPI module 0 signal 5.
	U5Rx	I	TTL	UART module 5 receive.
L8	GND	-	Power	Ground reference for logic and I/O pins.
L9	GND	-	Power	Ground reference for logic and I/O pins.
L10	VDD	-	Power	Positive supply for I/O and some logic.
L11	VDD	-	Power	Positive supply for I/O and some logic.
L12	VDD	-	Power	Positive supply for I/O and some logic.
L18	PM2	I/O	TTL	GPIO port M bit 2.
	EPI0S13	I/O	TTL	EPI module 0 signal 13.
	T3CCP0	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 0.
L19	PM3	I/O	TTL	GPIO port M bit 3.
	EPI0S12	I/O	TTL	EPI module 0 signal 12.
	T3CCP1	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 1.
M1	PC5	I/O	TTL	GPIO port C bit 5.
	C1+	I	Analog	Analog comparator 1 positive input.
	EPI0S6	I/O	TTL	EPI module 0 signal 6.
	RTCCLK	O	TTL	Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset.
	T7CCP1	I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 1.
	U7Tx	O	TTL	UART module 7 transmit.
M2	PC4	I/O	TTL	GPIO port C bit 4.
	C1-	I	Analog	Analog comparator 1 negative input.
	EPI0S7	I/O	TTL	EPI module 0 signal 7.
	T7CCP0	I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 0.
	U7Rx	I	TTL	UART module 7 receive.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
M3	PQ7	I/O	TTL	GPIO port Q bit 7.
	U1RI	I	TTL	UART module 1 Ring Indicator modem status input signal.
M4	PQ3	I/O	TTL	GPIO port Q bit 3.
	EPI0S23	I/O	TTL	EPI module 0 signal 23.
	SSI3XDAT1	I/O	TTL	SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode).
	T7CCP1	I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 1.
M8	GND	-	Power	Ground reference for logic and I/O pins.
M9	GND	-	Power	Ground reference for logic and I/O pins.
M10	GND	-	Power	Ground reference for logic and I/O pins.
M11	VDD	-	Power	Positive supply for I/O and some logic.
M12	VDD	-	Power	Positive supply for I/O and some logic.
M16	PG3	I/O	TTL	GPIO port G bit 3.
	EN0TXEN	O	TTL	Ethernet 0 Transmit Enable.
	I2C2SDA	I/O	OD	I ² C module 2 data.
	SSI2XDAT2	I/O	TTL	SSI Module 2 Bi-directional Data Pin 2.
M17	HIB	O	TTL	An output that indicates the processor is in Hibernate mode.
M18	PM4	I/O	TTL	GPIO port M bit 4.
	EN0RREF_CLK	I/O	TTL	Ethernet 0 Reference Clock.
	T4CCP0	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 0.
	TMPPR3	I/O	TTL	Tamper signal 3.
	U0CTS	I	TTL	UART module 0 Clear To Send modem flow control input signal.
N1	PJ6	I/O	TTL	GPIO port J bit 6.
	LCDAC	O	TTL	LCD AC bias or latch enable in Raster mode; Primary chip select (CS0)/Primary Enable (E0) in LIDD MPU/Hitachi mode
	U4RTS	O	TTL	UART module 4 Request to Send modem flow control output line.
N2	PR2	I/O	TTL	GPIO port R bit 2.
	I2C2SCL	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	LCDLP	O	TTL	LCD Line Clock or HSYNC in Raster mode; Write Strobe or Direction bit in LIDD mode
	M0PWM2	O	TTL	Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.
N4	PR1	I/O	TTL	GPIO port R bit 1.
	I2C1SDA	I/O	OD	I ² C module 1 data.
	LCDFP	O	TTL	LCD Frame Clock or VSYNC in Raster mode; Address Latch Enable in LIDD mode
	M0PWM1	O	TTL	Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.
	U4Rx	I	TTL	UART module 4 receive.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
N5	PR0	I/O	TTL	GPIO port R bit 0.
	I2C1SCL	I/O	OD	I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	LCDCP	O	TTL	LCD Pixel Clock in Raster mode; read strobe or read/write strobe in LIDD mode
	M0PWM0	O	TTL	Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.
	U4Tx	O	TTL	UART module 4 transmit.
N10	GND	-	Power	Ground reference for logic and I/O pins.
N15	PG0	I/O	TTL	GPIO port G bit 0.
	EN0PPS	O	TTL	Ethernet 0 Pulse-Per-Second (PPS) Output.
	EPI0S11	I/O	TTL	EPI module 0 signal 11.
	I2C1SCL	I/O	OD	I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	M0PWM4	O	TTL	Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.
N16	VDD	-	Power	Positive supply for I/O and some logic.
N18	PM7	I/O	TTL	GPIO port M bit 7.
	EN0COL	I	TTL	Ethernet 0 Collision Detect.
	T5CCP1	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 1.
	TMPR0	I/O	TTL	Tamper signal 0.
	U0RI	I	TTL	UART module 0 Ring Indicator modem status input signal.
N19	PM6	I/O	TTL	GPIO port M bit 6.
	EN0CRS	I	TTL	Ethernet 0 Carrier Sense.
	T5CCP0	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 0.
	TMPR1	I/O	TTL	Tamper signal 1.
	U0DSR	I	TTL	UART module 0 Data Set Ready modem output control line.
P2	PR5	I/O	TTL	GPIO port R bit 5.
	I2C3SDA	I/O	OD	I ² C module 3 data.
	LCDDATA01	I/O	TTL	LCD Data Pin 1 input/output.
	M0PWM5	O	TTL	Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.
	T0CCP1	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
	U1Rx	I	TTL	UART module 1 receive.
P3	PR4	I/O	TTL	GPIO port R bit 4.
	I2C3SCL	I/O	OD	I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	LCDDATA00	I/O	TTL	LCD Data Pin 0 input/output.
	M0PWM4	O	TTL	Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.
	T0CCP0	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 0.
P4	PH0	I/O	TTL	GPIO port H bit 0.
	EPI0S0	I/O	TTL	EPI module 0 signal 0.
	U0RTS	O	TTL	UART module 0 Request to Send modem flow control output signal.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
P10	VDD	-	Power	Positive supply for I/O and some logic.
P16	GND	-	Power	Ground reference for logic and I/O pins.
P17	VDD	-	Power	Positive supply for I/O and some logic.
P18	RST	I	TTL	System reset input.
P19	VBAT	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
R1	PH2	I/O	TTL	GPIO port H bit 2.
	EPI0S2	I/O	TTL	EPI module 0 signal 2.
	U0DCD	I	TTL	UART module 0 Data Carrier Detect modem status input signal.
R2	PH1	I/O	TTL	GPIO port H bit 1.
	EPI0S1	I/O	TTL	EPI module 0 signal 1.
	U0CTS	I	TTL	UART module 0 Clear To Send modem flow control input signal.
R3	PH4	I/O	TTL	GPIO port H bit 4.
	U0DTR	O	TTL	UART module 0 Data Terminal Ready modem status input signal.
R7	PA7	I/O	TTL	GPIO port A bit 7.
	EPI0S9	I/O	TTL	EPI module 0 signal 9.
	I2C6SDA	I/O	OD	I ² C module 6 data.
	SSI0XDAT3	I/O	TTL	SSI Module 0 Bi-directional Data Pin 3.
	T3CCP1	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 1.
	U2Tx	O	TTL	UART module 2 transmit.
	USB0EPEN	O	TTL	Optionally used in Host mode to control an external power source to supply power to the USB bus.
	USB0PFLT	I	TTL	Optionally used in Host mode by an external power source to indicate an error state by that power source.
R10	PR7	I/O	TTL	GPIO port R bit 7.
	EN0TXEN	O	TTL	Ethernet 0 Transmit Enable.
	I2C4SDA	I/O	OD	I ² C module 4 data.
	LCDDATA05	I/O	TTL	LCD Data Pin 5 input/output.
	M0PWM7	O	TTL	Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.
	T1CCP1	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.
R13	PS7	I/O	TTL	GPIO port S bit 7.
	EN0RXDV	I	TTL	Ethernet 0 Receive Data Valid.
	LCDDATA09	I/O	TTL	LCD Data Pin 9 input/output.
	T5CCP1	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 1.
R17	GND	-	Power	Ground reference for logic and I/O pins.
R18	GNDX	-	Power	GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.
T1	PH3	I/O	TTL	GPIO port H bit 3.
	EPI0S3	I/O	TTL	EPI module 0 signal 3.
	U0DSR	I	TTL	UART module 0 Data Set Ready modem output control line.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
T2	PH5	I/O	TTL	GPIO port H bit 5.
	EN0PPS	O	TTL	Ethernet 0 Pulse-Per-Second (PPS) Output.
	U0RI	I	TTL	UART module 0 Ring Indicator modem status input signal.
T6	PA2	I/O	TTL	GPIO port A bit 2.
	I2C8SCL	I/O	OD	I ² C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	SSI0Clk	I/O	TTL	SSI module 0 clock
	T1CCP0	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.
	U4Rx	I	TTL	UART module 4 receive.
T7	PF3	I/O	TTL	GPIO port F bit 3.
	EN0MDIO	I/O	TTL	Ethernet 0 Management Data Input/Output signal.
	M0PWM3	O	TTL	Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.
	SSI3Clk	I/O	TTL	SSI module 3 clock.
	TRCLK	O	TTL	Trace clock.
T8	PF6	I/O	TTL	GPIO port F bit 6.
	LCDMCLK	O	TTL	LCD Memory Clock/Secondary chip Select (CS1)/Secondary Enable (E1) in LIDD Synchronous/Async MPU/Hitachi mode
T12	PN6	I/O	TTL	GPIO port N bit 6.
	EN0TXER	O	TTL	Ethernet 0 transmit error.
	LCDDATA13	I/O	TTL	LCD Data Pin 13 input/output.
	U4RTS	O	TTL	UART module 4 Request to Send modem flow control output line.
T13	PS5	I/O	TTL	GPIO port S bit 5.
	EN0TXD1	O	TTL	Ethernet 0 Transmit Data 1.
	LCDDATA07	I/O	TTL	LCD Data Pin 7 input/output.
	PhB0	I	TTL	QEI module 0 phase B.
	T4CCP1	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 1.
T14	PG1	I/O	TTL	GPIO port G bit 1.
	EPI0S10	I/O	TTL	EPI module 0 signal 10.
	I2C1SDA	I/O	OD	I ² C module 1 data.
	M0PWM5	O	TTL	Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.
T18	XOSC0	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
T19	XOSC1	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.
U2	PH6	I/O	TTL	GPIO port H bit 6.
	U5Rx	I	TTL	UART module 5 receive.
	U7Rx	I	TTL	UART module 7 receive.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
U5	PA3	I/O	TTL	GPIO port A bit 3.
	I2C8SDA	I/O	OD	I ² C module 8 data.
	SSI0FSS	I/O	TTL	SSI module 0 frame signal
	T1CCP1	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.
	U4Tx	O	TTL	UART module 4 transmit.
U6	PF0	I/O	TTL	GPIO port F bit 0.
	EN0LED0	O	TTL	Ethernet 0 LED 0.
	M0PWM0	O	TTL	Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.
	SSI3XDAT1	I/O	TTL	SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode).
	TRD2	O	TTL	Trace data 2.
U8	PF7	I/O	TTL	GPIO port F bit 7.
	LCDDATA02	I/O	TTL	LCD Data Pin 2 input/output.
U10	PS6	I/O	TTL	GPIO port S bit 6.
	EN0RXER	I	TTL	Ethernet 0 Receive Error.
	IDX0	I	TTL	QEI module 0 index.
	LCDDATA08	I/O	TTL	LCD Data Pin 8 input/output.
	T5CCP0	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 0.
U12	PN7	I/O	TTL	GPIO port N bit 7.
	LCDDATA12	I/O	TTL	LCD Data Pin 12 input/output.
	U1RTS	O	TTL	UART module 1 Request to Send modem flow control output line.
	U4CTS	I	TTL	UART module 4 Clear To Send modem flow control input signal.
U14	PG7	I/O	TTL	GPIO port G bit 7.
	EN0RXDV	I	TTL	Ethernet 0 Receive Data Valid.
	I2C4SDA	I/O	OD	I ² C module 4 data.
	OWIRE	I/O	TTL	1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled.
	SSI2Clk	I/O	TTL	SSI module 2 clock.
U15	PQ6	I/O	TTL	GPIO port Q bit 6.
	EN0RXD1	I	TTL	Ethernet 0 Receive Data 1.
	U1DTR	O	TTL	UART module 1 Data Terminal Ready modem status input signal.
U18	WAKE	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
U19	PK4	I/O	TTL	GPIO port K bit 4.
	EN0INTRN	I	TTL	Ethernet 0 Interrupt from the Ethernet PHY.
	EN0LED0	O	TTL	Ethernet 0 LED 0.
	EN0RXD3	I	TTL	Ethernet 0 Receive Data 3.
	EPI0S32	I/O	TTL	EPI module 0 signal 32.
	I2C3SCL	I/O	OD	I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	M0PWM6	O	TTL	Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
V1	GND	-	Power	Ground reference for logic and I/O pins.
V2	PH7	I/O	TTL	GPIO port H bit 7.
	U5Tx	O	TTL	UART module 5 transmit.
	U7Tx	O	TTL	UART module 7 transmit.
V3	PA0	I/O	TTL	GPIO port A bit 0.
	CAN0Rx	I	TTL	CAN module 0 receive.
	I2C9SCL	I/O	OD	I ² C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	T0CCP0	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 0.
	U0Rx	I	TTL	UART module 0 receive.
V4	PA4	I/O	TTL	GPIO port A bit 4.
	I2C7SCL	I/O	OD	I ² C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	SSI0XDAT0	I/O	TTL	SSI Module 0 Bi-directional Data Pin 0 (SSI0TX in Legacy SSI Mode).
	T2CCP0	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 0.
	U3Rx	I	TTL	UART module 3 receive.
V5	PA6	I/O	TTL	GPIO port A bit 6.
	EN0RXCK	I	TTL	Ethernet 0 Receive Clock.
	EPI0S8	I/O	TTL	EPI module 0 signal 8.
	I2C6SCL	I/O	OD	I ² C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	SSI0XDAT2	I/O	TTL	SSI Module 0 Bi-directional Data Pin 2.
	T3CCP0	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 0.
	U2Rx	I	TTL	UART module 2 receive.
V6	USB0EPEN	O	TTL	Optionally used in Host mode to control an external power source to supply power to the USB bus.
	PF1	I/O	TTL	GPIO port F bit 1.
	EN0LED2	O	TTL	Ethernet 0 LED 2.
	M0PWM1	O	TTL	Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.
	SSI3XDAT0	I/O	TTL	SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode).
V7	TRD1	O	TTL	Trace data 1.
	PF4	I/O	TTL	GPIO port F bit 4.
	EN0LED1	O	TTL	Ethernet 0 LED 1.
	M0FAULT0	I	TTL	Motion Control Module 0 PWM Fault 0.
	SSI3XDAT2	I/O	TTL	SSI Module 3 Bi-directional Data Pin 2.
V8	TRD3	O	TTL	Trace data 3.
	PR3	I/O	TTL	GPIO port R bit 3.
	I2C2SDA	I/O	OD	I ² C module 2 data.
	LCDDATA03	I/O	TTL	LCD Data Pin 3 input/output.
V8	M0PWM3	O	TTL	Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
V9	PS4	I/O	TTL	GPIO port S bit 4.
	EN0TXD0	O	TTL	Ethernet 0 Transmit Data 0.
	LCDDATA06	I/O	TTL	LCD Data Pin 6 input/output.
	PhA0	I	TTL	QEI module 0 phase A.
	T4CCP0	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 0.
V10	PT1	I/O	TTL	GPIO port T bit 1.
	CAN0Tx	O	TTL	CAN module 0 transmit.
	EN0RXD1	I	TTL	Ethernet 0 Receive Data 1.
	LCDDATA11	I/O	TTL	LCD Data Pin 11 input/output.
	T6CCP1	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 1.
V11	PG2	I/O	TTL	GPIO port G bit 2.
	EN0TXCK	I	TTL	Ethernet 0 Transmit Clock.
	I2C2SCL	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	SSI2XDAT3	I/O	TTL	SSI Module 2 Bi-directional Data Pin 3.
V12	PG6	I/O	TTL	GPIO port G bit 6.
	EN0RXER	I	TTL	Ethernet 0 Receive Error.
	I2C4SCL	I/O	OD	I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	OWIRE	I/O	TTL	1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled.
	SSI2FSS	I/O	TTL	SSI module 2 frame signal.
V13	EN0RXIN	I/O	TTL	Ethernet PHY negative receive differential input.
V14	EN0TXON	I/O	TTL	Ethernet PHY negative transmit differential output.
V15	EN0TXOP	I/O	TTL	Ethernet PHY positive transmit differential output.
V16	PK6	I/O	TTL	GPIO port K bit 6.
	EN0LED1	O	TTL	Ethernet 0 LED 1.
	EN0TXD2	O	TTL	Ethernet 0 Transmit Data 2.
	EPI0S25	I/O	TTL	EPI module 0 signal 25.
	I2C4SCL	I/O	OD	I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	M0FAULT1	I	TTL	Motion Control Module 0 PWM Fault 1.
V17	PK5	I/O	TTL	GPIO port K bit 5.
	ENOLED2	O	TTL	Ethernet 0 LED 2.
	EN0RXD2	I	TTL	Ethernet 0 Receive Data 2.
	EPI0S31	I/O	TTL	EPI module 0 signal 31.
	I2C3SDA	I/O	OD	I ² C module 3 data.
	M0PWM7	O	TTL	Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.
V18	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
V19	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
W1	GND	-	Power	Ground reference for logic and I/O pins.
W2	GND	-	Power	Ground reference for logic and I/O pins.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
W3	PA1	I/O	TTL	GPIO port A bit 1.
	CAN0Tx	O	TTL	CAN module 0 transmit.
	I2C9SDA	I/O	OD	I ² C module 9 data.
	T0CCP1	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
	U0Tx	O	TTL	UART module 0 transmit.
W4	PA5	I/O	TTL	GPIO port A bit 5.
	I2C7SDA	I/O	OD	I ² C module 7 data.
	SSI0XDAT1	I/O	TTL	SSI Module 0 Bi-directional Data Pin 1 (SSI0RX in Legacy SSI Mode).
	T2CCP1	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 1.
	U3Tx	O	TTL	UART module 3 transmit.
W6	PF2	I/O	TTL	GPIO port F bit 2.
	EN0MDC	O	TTL	Ethernet 0 Management Data Clock.
	M0PWM2	O	TTL	Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.
	SSI3FSS	I/O	TTL	SSI module 3 frame signal.
	TRD0	O	TTL	Trace data 0.
W7	PF5	I/O	TTL	GPIO port F bit 5.
	SSI3XDAT3	I/O	TTL	SSI Module 3 Bi-directional Data Pin 3.
W9	PR6	I/O	TTL	GPIO port R bit 6.
	I2C4SCL	I/O	OD	I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	LCDDATA04	I/O	TTL	LCD Data Pin 4 input/output.
	M0PWM6	O	TTL	Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.
	T1CCP0	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.
	U1Tx	O	TTL	UART module 1 transmit.
W10	PT0	I/O	TTL	GPIO port T bit 0.
	CAN0Rx	I	TTL	CAN module 0 receive.
	EN0RXD0	I	TTL	Ethernet 0 Receive Data 0.
	LCDDATA10	I/O	TTL	LCD Data Pin 10 input/output.
	T6CCP0	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 0.
W12	PQ5	I/O	TTL	GPIO port Q bit 5.
	EN0RXD0	I	TTL	Ethernet 0 Receive Data 0.
	U1Tx	O	TTL	UART module 1 transmit.
W13	EN0RXIP	I/O	TTL	Ethernet PHY positive receive differential input.
W15	RBIAS	O	Analog	4.87-kΩ resistor (1% precision) for Ethernet PHY.

Table 31-2. Signals by Pin Number (continued)

Pin Number	Pin Name	Pin Type	Buffer Type	Description
W16	PK7	I/O	TTL	GPIO port K bit 7.
	EN0TXD3	O	TTL	Ethernet 0 Transmit Data 3.
	EPI0S24	I/O	TTL	EPI module 0 signal 24.
	I2C4SDA	I/O	OD	I ² C module 4 data.
	M0FAULT2	I	TTL	Motion Control Module 0 PWM Fault 2.
	RTCCLK	O	TTL	Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset.
	U0RI	I	TTL	UART module 0 Ring Indicator modem status input signal.
W18	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
W19	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.

31.2 Signals by Signal Name

Table 31-3. Signals by Signal Name

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
AIN0	G2	PE3	I	Analog	Analog-to-digital converter input 0.
AIN1	G1	PE2	I	Analog	Analog-to-digital converter input 1.
AIN2	H2	PE1	I	Analog	Analog-to-digital converter input 2.
AIN3	H3	PE0	I	Analog	Analog-to-digital converter input 3.
AIN4	B2	PD7	I	Analog	Analog-to-digital converter input 4.
AIN5	B3	PD6	I	Analog	Analog-to-digital converter input 5.
AIN6	B4	PD5	I	Analog	Analog-to-digital converter input 6.
AIN7	A4	PD4	I	Analog	Analog-to-digital converter input 7.
AIN8	B5	PE5	I	Analog	Analog-to-digital converter input 8.
AIN9	A5	PE4	I	Analog	Analog-to-digital converter input 9.
AIN10	C6	PB4	I	Analog	Analog-to-digital converter input 10.
AIN11	B6	PB5	I	Analog	Analog-to-digital converter input 11.
AIN12	D1	PD3	I	Analog	Analog-to-digital converter input 12.
AIN13	D2	PD2	I	Analog	Analog-to-digital converter input 13.
AIN14	C1	PD1	I	Analog	Analog-to-digital converter input 14.
AIN15	C2	PD0	I	Analog	Analog-to-digital converter input 15.
AIN16	J1	PK0	I	Analog	Analog-to-digital converter input 16.
AIN17	J2	PK1	I	Analog	Analog-to-digital converter input 17.
AIN18	K1	PK2	I	Analog	Analog-to-digital converter input 18.
AIN19	K2	PK3	I	Analog	Analog-to-digital converter input 19.
AIN20	A7	PE6	I	Analog	Analog-to-digital converter input 20.
AIN21	B7	PE7	I	Analog	Analog-to-digital converter input 21.
AIN22	A8	PP7	I	Analog	Analog-to-digital converter input 22.
AIN23	B8	PP6	I	Analog	Analog-to-digital converter input 23.
C0+	L2	PC6	I	Analog	Analog comparator 0 positive input.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
C0-	K3	PC7	I	Analog	Analog comparator 0 negative input.
C0o	C2 G18	PD0 (5) PL2 (5)	O	TTL	Analog comparator 0 output.
C1+	M1	PC5	I	Analog	Analog comparator 1 positive input.
C1-	M2	PC4	I	Analog	Analog comparator 1 negative input.
C1o	C1 J18	PD1 (5) PL3 (5)	O	TTL	Analog comparator 1 output.
C2+	D6	PP0	I	Analog	Analog comparator 2 positive input.
C2-	D7	PP1	I	Analog	Analog comparator 2 negative input.
C2o	D2	PD2 (5)	O	TTL	Analog comparator 2 output.
CAN0Rx	V3 W10	PA0 (7) PT0 (7)	I	TTL	CAN module 0 receive.
CAN0Tx	W3 V10	PA1 (7) PT1 (7)	O	TTL	CAN module 0 transmit.
CAN1Rx	A16 E18	PB0 (7) PT2 (7)	I	TTL	CAN module 1 receive.
CAN1Tx	B16 F17	PB1 (7) PT3 (7)	O	TTL	CAN module 1 transmit.
DIVSCLK	A13	PQ4 (7)	O	TTL	An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock.
EN0COL	N18	PM7 (14)	I	TTL	Ethernet 0 Collision Detect.
EN0CRS	N19	PM6 (14)	I	TTL	Ethernet 0 Carrier Sense.
EN0INTRN	U19 D6	PK4 (7) PP0 (7)	I	TTL	Ethernet 0 Interrupt from the Ethernet PHY.
EN0LED0	U6 U19	PF0 (5) PK4 (5)	O	TTL	Ethernet 0 LED 0.
EN0LED1	V7 V16	PF4 (5) PK6 (5)	O	TTL	Ethernet 0 LED 1.
EN0LED2	V6 V17	PF1 (5) PK5 (5)	O	TTL	Ethernet 0 LED 2.
EN0MDC	A17 W6	PB2 (5) PF2 (5)	O	TTL	Ethernet 0 Management Data Clock.
EN0MDIO	B17 T7	PB3 (5) PF3 (5)	I/O	TTL	Ethernet 0 Management Data Input/Output signal.
EN0PPS	N15 T2 C8	PG0 (5) PH5 (5) PJ0 (5)	O	TTL	Ethernet 0 Pulse-Per-Second (PPS) Output.
EN0RREF_CLK	M18	PM4 (14)	I/O	TTL	Ethernet 0 Reference Clock.
EN0RXCK	V5	PA6 (14)	I	TTL	Ethernet 0 Receive Clock.
EN0RXD0	W12 W10	PQ5 (14) PT0 (14)	I	TTL	Ethernet 0 Receive Data 0.
EN0RXD1	U15 V10	PQ6 (14) PT1 (14)	I	TTL	Ethernet 0 Receive Data 1.
EN0RXD2	V17	PK5 (14)	I	TTL	Ethernet 0 Receive Data 2.
EN0RXD3	U19	PK4 (14)	I	TTL	Ethernet 0 Receive Data 3.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
EN0RXDV	U14 R13	PG7 (14) PS7 (14)	I	TTL	Ethernet 0 Receive Data Valid.
EN0RXER	V12 U10	PG6 (14) PS6 (14)	I	TTL	Ethernet 0 Receive Error.
EN0RXIN	V13	fixed	I/O	TTL	Ethernet PHY negative receive differential input.
EN0RXIP	W13	fixed	I/O	TTL	Ethernet PHY positive receive differential input.
EN0TXCK	V11	PG2 (14)	I	TTL	Ethernet 0 Transmit Clock.
EN0TXD0	K17 V9	PG4 (14) PS4 (14)	O	TTL	Ethernet 0 Transmit Data 0.
EN0TXD1	K15 T13	PG5 (14) PS5 (14)	O	TTL	Ethernet 0 Transmit Data 1.
EN0TXD2	V16	PK6 (14)	O	TTL	Ethernet 0 Transmit Data 2.
EN0TXD3	W16	PK7 (14)	O	TTL	Ethernet 0 Transmit Data 3.
EN0TXEN	M16 R10	PG3 (14) PR7 (14)	O	TTL	Ethernet 0 Transmit Enable.
EN0TXER	T12	PN6 (14)	O	TTL	Ethernet 0 transmit error.
EN0TXON	V14	fixed	I/O	TTL	Ethernet PHY negative transmit differential output.
EN0TXOP	V15	fixed	I/O	TTL	Ethernet PHY positive transmit differential output.
EPI0S0	P4 J1	PH0 (15) PK0 (15)	I/O	TTL	EPI module 0 signal 0.
EPI0S1	R2 J2	PH1 (15) PK1 (15)	I/O	TTL	EPI module 0 signal 1.
EPI0S2	R1 K1	PH2 (15) PK2 (15)	I/O	TTL	EPI module 0 signal 2.
EPI0S3	T1 K2	PH3 (15) PK3 (15)	I/O	TTL	EPI module 0 signal 3.
EPI0S4	K3	PC7 (15)	I/O	TTL	EPI module 0 signal 4.
EPI0S5	L2	PC6 (15)	I/O	TTL	EPI module 0 signal 5.
EPI0S6	M1	PC5 (15)	I/O	TTL	EPI module 0 signal 6.
EPI0S7	M2	PC4 (15)	I/O	TTL	EPI module 0 signal 7.
EPI0S8	V5	PA6 (15)	I/O	TTL	EPI module 0 signal 8.
EPI0S9	R7	PA7 (15)	I/O	TTL	EPI module 0 signal 9.
EPI0S10	T14	PG1 (15)	I/O	TTL	EPI module 0 signal 10.
EPI0S11	N15	PG0 (15)	I/O	TTL	EPI module 0 signal 11.
EPI0S12	L19	PM3 (15)	I/O	TTL	EPI module 0 signal 12.
EPI0S13	L18	PM2 (15)	I/O	TTL	EPI module 0 signal 13.
EPI0S14	K19	PM1 (15)	I/O	TTL	EPI module 0 signal 14.
EPI0S15	K18	PM0 (15)	I/O	TTL	EPI module 0 signal 15.
EPI0S16	G16	PL0 (15)	I/O	TTL	EPI module 0 signal 16.
EPI0S17	H19	PL1 (15)	I/O	TTL	EPI module 0 signal 17.
EPI0S18	G18	PL2 (15)	I/O	TTL	EPI module 0 signal 18.
EPI0S19	J18	PL3 (15)	I/O	TTL	EPI module 0 signal 19.
EPI0S20	E3	PQ0 (15)	I/O	TTL	EPI module 0 signal 20.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
EPIOS21	E2	PQ1 (15)	I/O	TTL	EPI module 0 signal 21.
EPIOS22	H4	PQ2 (15)	I/O	TTL	EPI module 0 signal 22.
EPIOS23	M4	PQ3 (15)	I/O	TTL	EPI module 0 signal 23.
EPIOS24	W16	PK7 (15)	I/O	TTL	EPI module 0 signal 24.
EPIOS25	V16	PK6 (15)	I/O	TTL	EPI module 0 signal 25.
EPIOS26	H18	PL4 (15)	I/O	TTL	EPI module 0 signal 26.
EPIOS27	A17	PB2 (15)	I/O	TTL	EPI module 0 signal 27.
EPIOS28	B17	PB3 (15)	I/O	TTL	EPI module 0 signal 28.
EPIOS29	A11 B13	PN2 (15) PP2 (15)	I/O	TTL	EPI module 0 signal 29.
EPIOS30	B10 C12	PN3 (15) PP3 (15)	I/O	TTL	EPI module 0 signal 30.
EPIOS31	V17	PK5 (15)	I/O	TTL	EPI module 0 signal 31.
EPIOS32	U19	PK4 (15)	I/O	TTL	EPI module 0 signal 32.
EPIOS33	G19	PL5 (15)	I/O	TTL	EPI module 0 signal 33.
EPIOS34	A10	PN4 (15)	I/O	TTL	EPI module 0 signal 34.
EPIOS35	B9	PN5 (15)	I/O	TTL	EPI module 0 signal 35.
GND	F10 H10 H11 H12 J11 J12 K6 K9 P16 K10 R17 K13 K14 L8 L9 M8 M9 M10 N10 A1 A2 B1 V1 W1 W2 A18 A19 B19	fixed	-	Power	Ground reference for logic and I/O pins.
GNDA	G4	fixed	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
GNDX	R18	fixed	-	Power	GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.
GNDX2	D18	fixed	-	Power	GND for the MOSC. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.
HIB	M17	fixed	O	TTL	An output that indicates the processor is in Hibernate mode.
I2C0SCL	A17	PB2 (2)	I/O	OD	I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C0SDA	B17	PB3 (2)	I/O	OD	I ² C module 0 data.
I2C1SCL	N15 N5	PG0 (2) PR0 (2)	I/O	OD	I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C1SDA	T14 N4	PG1 (2) PR1 (2)	I/O	OD	I ² C module 1 data.
I2C2SCL	V11 H19 B9 B12 N2	PG2 (2) PL1 (2) PN5 (3) PP5 (2) PR2 (2)	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C2SDA	M16 G16 A10 B8 V8	PG3 (2) PL0 (2) PN4 (3) PP6 (2) PR3 (2)	I/O	OD	I ² C module 2 data.
I2C3SCL	K17 U19 P3	PG4 (2) PK4 (2) PR4 (2)	I/O	OD	I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C3SDA	K15 V17 P2	PG5 (2) PK5 (2) PR5 (2)	I/O	OD	I ² C module 3 data.
I2C4SCL	V12 V16 W9	PG6 (2) PK6 (2) PR6 (2)	I/O	OD	I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C4SDA	U14 W16 R10	PG7 (2) PK7 (2) PR7 (2)	I/O	OD	I ² C module 4 data.
I2C5SCL	A16 C6	PB0 (2) PB4 (2)	I/O	OD	I ² C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C5SDA	B16 B6	PB1 (2) PB5 (2)	I/O	OD	I ² C module 5 data.
I2C6SCL	V5 F2	PA6 (2) PB6 (2)	I/O	OD	I ² C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.

Table 31-3. Signals by Signal Name (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
I2C6SDA	R7 F1	PA7 (2) PB7 (2)	I/O	OD	I ² C module 6 data.
I2C7SCL	V4 C2	PA4 (2) PD0 (2)	I/O	OD	I ² C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C7SDA	W4 C1	PA5 (2) PD1 (2)	I/O	OD	I ² C module 7 data.
I2C8SCL	T6 D2	PA2 (2) PD2 (2)	I/O	OD	I ² C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C8SDA	U5 D1	PA3 (2) PD3 (2)	I/O	OD	I ² C module 8 data.
I2C9SCL	V3 A7	PA0 (2) PE6 (2)	I/O	OD	I ² C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
I2C9SDA	W3 B7	PA1 (2) PE7 (2)	I/O	OD	I ² C module 9 data.
IDX0	J18 U10	PL3 (6) PS6 (6)	I	TTL	QEI module 0 index.
LCDAC	N1	PJ6 (15)	O	TTL	LCD AC bias or latch enable in Raster mode; Primary chip select (CS0)/Primary Enable (E0) in LIDD MPU/Hitachi mode
LCDCP	N5	PR0 (15)	O	TTL	LCD Pixel Clock in Raster mode; read strobe or read/write strobe in LIDD mode
LCDDATA00	P3	PR4 (15)	I/O	TTL	LCD Data Pin 0 input/output.
LCDDATA01	P2	PR5 (15)	I/O	TTL	LCD Data Pin 1 input/output.
LCDDATA02	U8	PF7 (15)	I/O	TTL	LCD Data Pin 2 input/output.
LCDDATA03	V8	PR3 (15)	I/O	TTL	LCD Data Pin 3 input/output.
LCDDATA04	W9	PR6 (15)	I/O	TTL	LCD Data Pin 4 input/output.
LCDDATA05	R10	PR7 (15)	I/O	TTL	LCD Data Pin 5 input/output.
LCDDATA06	V9	PS4 (15)	I/O	TTL	LCD Data Pin 6 input/output.
LCDDATA07	T13	PS5 (15)	I/O	TTL	LCD Data Pin 7 input/output.
LCDDATA08	U10	PS6 (15)	I/O	TTL	LCD Data Pin 8 input/output.
LCDDATA09	R13	PS7 (15)	I/O	TTL	LCD Data Pin 9 input/output.
LCDDATA10	W10	PT0 (15)	I/O	TTL	LCD Data Pin 10 input/output.
LCDDATA11	V10	PT1 (15)	I/O	TTL	LCD Data Pin 11 input/output.
LCDDATA12	U12	PN7 (15)	I/O	TTL	LCD Data Pin 12 input/output.
LCDDATA13	T12	PN6 (15)	I/O	TTL	LCD Data Pin 13 input/output.
LCDDATA14	H17	PJ2 (15)	I/O	TTL	LCD Data Pin 14 input/output.
LCDDATA15	F16	PJ3 (15)	I/O	TTL	LCD Data Pin 15 input/output.
LCDDATA16	F18	PJ4 (15)	O	TTL	LCD Data Pin 16 output.
LCDDATA17	E17	PJ5 (15)	O	TTL	LCD Data Pin 17 output.
LCDDATA18	E18	PT2 (15)	O	TTL	LCD Data Pin 18 output.
LCDDATA19	F17	PT3 (15)	O	TTL	LCD Data Pin 19 output.
LCDDATA20	D12	PS0 (15)	O	TTL	LCD Data Pin 20 output.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
LCDDATA21	D13	PS1 (15)	O	TTL	LCD Data Pin 21 output.
LCDDATA22	B14	PS2 (15)	O	TTL	LCD Data Pin 22 output.
LCDDATA23	A14	PS3 (15)	O	TTL	LCD Data Pin 23 output.
LCDFP	N4	PR1 (15)	O	TTL	LCD Frame Clock or VSYNC in Raster mode; Address Latch Enable in LIDD mode
LCDLP	N2	PR2 (15)	O	TTL	LCD Line Clock or HSYNC in Raster mode; Write Strobe or Direction bit in LIDD mode
LCDMCLK	T8	PF6 (15)	O	TTL	LCD Memory Clock/Secondary chip Select (CS1)/Secondary Enable (E1) in LIDD Synchronous/Async MPU/Hitachi mode
M0FAULT0	V7 D12	PF4 (6) PS0 (6)	I	TTL	Motion Control Module 0 PWM Fault 0.
M0FAULT1	V16 D13	PK6 (6) PS1 (6)	I	TTL	Motion Control Module 0 PWM Fault 1.
M0FAULT2	W16 B14	PK7 (6) PS2 (6)	I	TTL	Motion Control Module 0 PWM Fault 2.
M0FAULT3	G16 A14	PL0 (6) PS3 (6)	I	TTL	Motion Control Module 0 PWM Fault 3.
M0PWM0	U6 N5	PF0 (6) PR0 (6)	O	TTL	Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.
M0PWM1	V6 N4	PF1 (6) PR1 (6)	O	TTL	Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.
M0PWM2	W6 N2	PF2 (6) PR2 (6)	O	TTL	Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.
M0PWM3	T7 V8	PF3 (6) PR3 (6)	O	TTL	Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.
M0PWM4	N15 P3	PG0 (6) PR4 (6)	O	TTL	Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.
M0PWM5	T14 P2	PG1 (6) PR5 (6)	O	TTL	Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.
M0PWM6	U19 W9	PK4 (6) PR6 (6)	O	TTL	Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.
M0PWM7	V17 R10	PK5 (6) PR7 (6)	O	TTL	Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.
NC	C5 V18 V19 W18 W19 E13	fixed	-	-	No connect. Leave the pin electrically unconnected/isolated.
NMI	B2 B7	PD7 (8) PE7 (8)	I	TTL	Non-maskable interrupt.
OSC0	E19	fixed	I	Analog	Main oscillator crystal input or an external clock reference input.
OSC1	D19	fixed	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
OWALT	K15 B12	PG5 (5) PP5 (4)	I/O	TTL	1-Wire Optional 2nd signal to be used as output.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
OWIRE	G2 K17 V12 U14 D8 A8	PE3 (5) PG4 (5) PG6 (5) PG7 (5) PP4 (4) PP7 (5)	I/O	TTL	1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled.
PA0	V3	-	I/O	TTL	GPIO port A bit 0.
PA1	W3	-	I/O	TTL	GPIO port A bit 1.
PA2	T6	-	I/O	TTL	GPIO port A bit 2.
PA3	U5	-	I/O	TTL	GPIO port A bit 3.
PA4	V4	-	I/O	TTL	GPIO port A bit 4.
PA5	W4	-	I/O	TTL	GPIO port A bit 5.
PA6	V5	-	I/O	TTL	GPIO port A bit 6.
PA7	R7	-	I/O	TTL	GPIO port A bit 7.
PB0	A16	-	I/O	TTL	GPIO port B bit 0.
PB1	B16	-	I/O	TTL	GPIO port B bit 1.
PB2	A17	-	I/O	TTL	GPIO port B bit 2.
PB3	B17	-	I/O	TTL	GPIO port B bit 3.
PB4	C6	-	I/O	TTL	GPIO port B bit 4.
PB5	B6	-	I/O	TTL	GPIO port B bit 5.
PB6	F2	-	I/O	TTL	GPIO port B bit 6.
PB7	F1	-	I/O	TTL	GPIO port B bit 7.
PC0	B15	-	I/O	TTL	GPIO port C bit 0.
PC1	C15	-	I/O	TTL	GPIO port C bit 1.
PC2	D14	-	I/O	TTL	GPIO port C bit 2.
PC3	C14	-	I/O	TTL	GPIO port C bit 3.
PC4	M2	-	I/O	TTL	GPIO port C bit 4.
PC5	M1	-	I/O	TTL	GPIO port C bit 5.
PC6	L2	-	I/O	TTL	GPIO port C bit 6.
PC7	K3	-	I/O	TTL	GPIO port C bit 7.
PD0	C2	-	I/O	TTL	GPIO port D bit 0.
PD1	C1	-	I/O	TTL	GPIO port D bit 1.
PD2	D2	-	I/O	TTL	GPIO port D bit 2.
PD3	D1	-	I/O	TTL	GPIO port D bit 3.
PD4	A4	-	I/O	TTL	GPIO port D bit 4.
PD5	B4	-	I/O	TTL	GPIO port D bit 5.
PD6	B3	-	I/O	TTL	GPIO port D bit 6.
PD7	B2	-	I/O	TTL	GPIO port D bit 7.
PE0	H3	-	I/O	TTL	GPIO port E bit 0.
PE1	H2	-	I/O	TTL	GPIO port E bit 1.
PE2	G1	-	I/O	TTL	GPIO port E bit 2.
PE3	G2	-	I/O	TTL	GPIO port E bit 3.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
PE4	A5	-	I/O	TTL	GPIO port E bit 4.
PE5	B5	-	I/O	TTL	GPIO port E bit 5.
PE6	A7	-	I/O	TTL	GPIO port E bit 6.
PE7	B7	-	I/O	TTL	GPIO port E bit 7.
PF0	U6	-	I/O	TTL	GPIO port F bit 0.
PF1	V6	-	I/O	TTL	GPIO port F bit 1.
PF2	W6	-	I/O	TTL	GPIO port F bit 2.
PF3	T7	-	I/O	TTL	GPIO port F bit 3.
PF4	V7	-	I/O	TTL	GPIO port F bit 4.
PF5	W7	-	I/O	TTL	GPIO port F bit 5.
PF6	T8	-	I/O	TTL	GPIO port F bit 6.
PF7	U8	-	I/O	TTL	GPIO port F bit 7.
PG0	N15	-	I/O	TTL	GPIO port G bit 0.
PG1	T14	-	I/O	TTL	GPIO port G bit 1.
PG2	V11	-	I/O	TTL	GPIO port G bit 2.
PG3	M16	-	I/O	TTL	GPIO port G bit 3.
PG4	K17	-	I/O	TTL	GPIO port G bit 4.
PG5	K15	-	I/O	TTL	GPIO port G bit 5.
PG6	V12	-	I/O	TTL	GPIO port G bit 6.
PG7	U14	-	I/O	TTL	GPIO port G bit 7.
PH0	P4	-	I/O	TTL	GPIO port H bit 0.
PH1	R2	-	I/O	TTL	GPIO port H bit 1.
PH2	R1	-	I/O	TTL	GPIO port H bit 2.
PH3	T1	-	I/O	TTL	GPIO port H bit 3.
PH4	R3	-	I/O	TTL	GPIO port H bit 4.
PH5	T2	-	I/O	TTL	GPIO port H bit 5.
PH6	U2	-	I/O	TTL	GPIO port H bit 6.
PH7	V2	-	I/O	TTL	GPIO port H bit 7.
PhA0	H19 V9	PL1 (6) PS4 (6)	I	TTL	QEI module 0 phase A.
PhB0	G18 T13	PL2 (6) PS5 (6)	I	TTL	QEI module 0 phase B.
PJ0	C8	-	I/O	TTL	GPIO port J bit 0.
PJ1	E7	-	I/O	TTL	GPIO port J bit 1.
PJ2	H17	-	I/O	TTL	GPIO port J bit 2.
PJ3	F16	-	I/O	TTL	GPIO port J bit 3.
PJ4	F18	-	I/O	TTL	GPIO port J bit 4.
PJ5	E17	-	I/O	TTL	GPIO port J bit 5.
PJ6	N1	-	I/O	TTL	GPIO port J bit 6.
PJ7	K5	-	I/O	TTL	GPIO port J bit 7.
PK0	J1	-	I/O	TTL	GPIO port K bit 0.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
PK1	J2	-	I/O	TTL	GPIO port K bit 1.
PK2	K1	-	I/O	TTL	GPIO port K bit 2.
PK3	K2	-	I/O	TTL	GPIO port K bit 3.
PK4	U19	-	I/O	TTL	GPIO port K bit 4.
PK5	V17	-	I/O	TTL	GPIO port K bit 5.
PK6	V16	-	I/O	TTL	GPIO port K bit 6.
PK7	W16	-	I/O	TTL	GPIO port K bit 7.
PL0	G16	-	I/O	TTL	GPIO port L bit 0.
PL1	H19	-	I/O	TTL	GPIO port L bit 1.
PL2	G18	-	I/O	TTL	GPIO port L bit 2.
PL3	J18	-	I/O	TTL	GPIO port L bit 3.
PL4	H18	-	I/O	TTL	GPIO port L bit 4.
PL5	G19	-	I/O	TTL	GPIO port L bit 5.
PL6	C18	-	I/O	TTL	GPIO port L bit 6.
PL7	B18	-	I/O	TTL	GPIO port L bit 7.
PM0	K18	-	I/O	TTL	GPIO port M bit 0.
PM1	K19	-	I/O	TTL	GPIO port M bit 1.
PM2	L18	-	I/O	TTL	GPIO port M bit 2.
PM3	L19	-	I/O	TTL	GPIO port M bit 3.
PM4	M18	-	I/O	TTL	GPIO port M bit 4.
PM5	G15	-	I/O	TTL	GPIO port M bit 5.
PM6	N19	-	I/O	TTL	GPIO port M bit 6.
PM7	N18	-	I/O	TTL	GPIO port M bit 7.
PN0	C10	-	I/O	TTL	GPIO port N bit 0.
PN1	B11	-	I/O	TTL	GPIO port N bit 1.
PN2	A11	-	I/O	TTL	GPIO port N bit 2.
PN3	B10	-	I/O	TTL	GPIO port N bit 3.
PN4	A10	-	I/O	TTL	GPIO port N bit 4.
PN5	B9	-	I/O	TTL	GPIO port N bit 5.
PN6	T12	-	I/O	TTL	GPIO port N bit 6.
PN7	U12	-	I/O	TTL	GPIO port N bit 7.
PP0	D6	-	I/O	TTL	GPIO port P bit 0.
PP1	D7	-	I/O	TTL	GPIO port P bit 1.
PP2	B13	-	I/O	TTL	GPIO port P bit 2.
PP3	C12	-	I/O	TTL	GPIO port P bit 3.
PP4	D8	-	I/O	TTL	GPIO port P bit 4.
PP5	B12	-	I/O	TTL	GPIO port P bit 5.
PP6	B8	-	I/O	TTL	GPIO port P bit 6.
PP7	A8	-	I/O	TTL	GPIO port P bit 7.
PQ0	E3	-	I/O	TTL	GPIO port Q bit 0.
PQ1	E2	-	I/O	TTL	GPIO port Q bit 1.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
PQ2	H4	-	I/O	TTL	GPIO port Q bit 2.
PQ3	M4	-	I/O	TTL	GPIO port Q bit 3.
PQ4	A13	-	I/O	TTL	GPIO port Q bit 4.
PQ5	W12	-	I/O	TTL	GPIO port Q bit 5.
PQ6	U15	-	I/O	TTL	GPIO port Q bit 6.
PQ7	M3	-	I/O	TTL	GPIO port Q bit 7.
PR0	N5	-	I/O	TTL	GPIO port R bit 0.
PR1	N4	-	I/O	TTL	GPIO port R bit 1.
PR2	N2	-	I/O	TTL	GPIO port R bit 2.
PR3	V8	-	I/O	TTL	GPIO port R bit 3.
PR4	P3	-	I/O	TTL	GPIO port R bit 4.
PR5	P2	-	I/O	TTL	GPIO port R bit 5.
PR6	W9	-	I/O	TTL	GPIO port R bit 6.
PR7	R10	-	I/O	TTL	GPIO port R bit 7.
PS0	D12	-	I/O	TTL	GPIO port S bit 0.
PS1	D13	-	I/O	TTL	GPIO port S bit 1.
PS2	B14	-	I/O	TTL	GPIO port S bit 2.
PS3	A14	-	I/O	TTL	GPIO port S bit 3.
PS4	V9	-	I/O	TTL	GPIO port S bit 4.
PS5	T13	-	I/O	TTL	GPIO port S bit 5.
PS6	U10	-	I/O	TTL	GPIO port S bit 6.
PS7	R13	-	I/O	TTL	GPIO port S bit 7.
PT0	W10	-	I/O	TTL	GPIO port T bit 0.
PT1	V10	-	I/O	TTL	GPIO port T bit 1.
PT2	E18	-	I/O	TTL	GPIO port T bit 2.
PT3	F17	-	I/O	TTL	GPIO port T bit 3.
RBIAS	W15	fixed	O	Analog	4.87-kΩ resistor (1% precision) for Ethernet PHY.
RST	P18	fixed	I	TTL	System reset input.
RTCCLK	M1 W16 C12	PC5 (7) PK7 (5) PP3 (7)	O	TTL	Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset.
SSI0Clk	T6	PA2 (15)	I/O	TTL	SSI module 0 clock
SSI0Fss	U5	PA3 (15)	I/O	TTL	SSI module 0 frame signal
SSI0XDAT0	V4	PA4 (15)	I/O	TTL	SSI Module 0 Bi-directional Data Pin 0 (SSI0TX in Legacy SSI Mode).
SSI0XDAT1	W4	PA5 (15)	I/O	TTL	SSI Module 0 Bi-directional Data Pin 1 (SSI0RX in Legacy SSI Mode).
SSI0XDAT2	V5	PA6 (13)	I/O	TTL	SSI Module 0 Bi-directional Data Pin 2.
SSI0XDAT3	R7	PA7 (13)	I/O	TTL	SSI Module 0 Bi-directional Data Pin 3.
SSI1Clk	B6	PB5 (15)	I/O	TTL	SSI module 1 clock.
SSI1Fss	C6	PB4 (15)	I/O	TTL	SSI module 1 frame signal.

Table 31-3. Signals by Signal Name (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
SSI1XDAT0	A5	PE4 (15)	I/O	TTL	SSI Module 1 Bi-directional Data Pin 0 (SSI1TX in Legacy SSI Mode).
SSI1XDAT1	B5	PE5 (15)	I/O	TTL	SSI Module 1 Bi-directional Data Pin 1 (SSI1RX in Legacy SSI Mode).
SSI1XDAT2	A4	PD4 (15)	I/O	TTL	SSI Module 1 Bi-directional Data Pin 2.
SSI1XDAT3	B4	PD5 (15)	I/O	TTL	SSI Module 1 Bi-directional Data Pin 3.
SSI2Clk	D1 U14	PD3 (15) PG7 (15)	I/O	TTL	SSI module 2 clock.
SSI2Fss	D2 V12	PD2 (15) PG6 (15)	I/O	TTL	SSI module 2 frame signal.
SSI2XDAT0	C1 K15	PD1 (15) PG5 (15)	I/O	TTL	SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode).
SSI2XDAT1	C2 K17	PD0 (15) PG4 (15)	I/O	TTL	SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode).
SSI2XDAT2	B2 M16	PD7 (15) PG3 (15)	I/O	TTL	SSI Module 2 Bi-directional Data Pin 2.
SSI2XDAT3	B3 V11	PD6 (15) PG2 (15)	I/O	TTL	SSI Module 2 Bi-directional Data Pin 3.
SSI3Clk	T7 E3	PF3 (14) PQ0 (14)	I/O	TTL	SSI module 3 clock.
SSI3Fss	W6 E2	PF2 (14) PQ1 (14)	I/O	TTL	SSI module 3 frame signal.
SSI3XDAT0	V6 H4	PF1 (14) PQ2 (14)	I/O	TTL	SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode).
SSI3XDAT1	U6 M4	PF0 (14) PQ3 (14)	I/O	TTL	SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode).
SSI3XDAT2	V7 D6	PF4 (14) PP0 (15)	I/O	TTL	SSI Module 3 Bi-directional Data Pin 2.
SSI3XDAT3	W7 D7	PF5 (14) PP1 (15)	I/O	TTL	SSI Module 3 Bi-directional Data Pin 3.
SWCLK	B15	PC0 (1)	I	TTL	JTAG/SWD CLK.
SWDIO	C15	PC1 (1)	I/O	TTL	JTAG TMS and SWDIO.
SWO	C14	PC3 (1)	O	TTL	JTAG TDO and SWO.

T0CCP1	W3 C1 G19 P2	PA1 (3) PD1 (3) PL5 (3) PR5 (3)	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
T1CCP0	T6 D2 C18 W9	PA2 (3) PD2 (3) PL6 (3) PR6 (3)	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.
T1CCP1	U5 D1 B18 R10	PA3 (3) PD3 (3) PL7 (3) PR7 (3)	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
T2CCP0	V4 K18 D12	PA4 (3) PM0 (3) PS0 (3)	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 0.
T2CCP1	W4 K19 D13	PA5 (3) PM1 (3) PS1 (3)	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 1.
T3CCP0	V5 A4 L18 B14	PA6 (3) PD4 (3) PM2 (3) PS2 (3)	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 0.
T3CCP1	R7 B4 L19 A14	PA7 (3) PD5 (3) PM3 (3) PS3 (3)	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 1.
T4CCP0	A16 B3 M18 V9	PB0 (3) PD6 (3) PM4 (3) PS4 (3)	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 0.
T4CCP1	B16 B2 G15 T13	PB1 (3) PD7 (3) PM5 (3) PS5 (3)	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 1.
T5CCP0	A17 N19 U10	PB2 (3) PM6 (3) PS6 (3)	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 0.
T5CCP1	B17 N18 R13	PB3 (3) PM7 (3) PS7 (3)	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 1.
T6CCP0	F2 D6 E3 W10	PB6 (3) PP0 (5) PQ0 (3) PT0 (3)	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 0.
T6CCP1	F1 D7 E2 V10	PB7 (3) PP1 (5) PQ1 (3) PT1 (3)	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 1.
T7CCP0	M2 H4 E18	PC4 (3) PQ2 (3) PT2 (3)	I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 0.
T7CCP1	M1 M4 F17	PC5 (3) PQ3 (3) PT3 (3)	I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 1.
TCK	B15	PC0 (1)	I	TTL	JTAG/SWD CLK.
TDI	D14	PC2 (1)	I	TTL	JTAG TDI.
TDO	C14	PC3 (1)	O	TTL	JTAG TDO and SWO.
TMPR0	N18	PM7	I/O	TTL	Tamper signal 0.
TMPR1	N19	PM6	I/O	TTL	Tamper signal 1.
TMPR2	G15	PM5	I/O	TTL	Tamper signal 2.
TMPR3	M18	PM4	I/O	TTL	Tamper signal 3.
TMS	C15	PC1 (1)	I	TTL	JTAG TMS and SWDIO.

Table 31-3. Signals by Signal Name (continued)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
TRCLK	T7	PF3 (15)	O	TTL	Trace clock.
TRD0	W6	PF2 (15)	O	TTL	Trace data 0.
TRD1	V6	PF1 (15)	O	TTL	Trace data 1.
TRD2	U6	PF0 (15)	O	TTL	Trace data 2.
TRD3	V7	PF4 (15)	O	TTL	Trace data 3.
U0CTS	C6 A7 K17 R2 M18	PB4 (1) PE6 (1) PG4 (1) PH1 (1) PM4 (1)	I	TTL	UART module 0 Clear To Send modem flow control input signal.
U0DCD	R1 G15 C12	PH2 (1) PM5 (1) PP3 (2)	I	TTL	UART module 0 Data Carrier Detect modem status input signal.
U0DSR	T1 N19 D8	PH3 (1) PM6 (1) PP4 (2)	I	TTL	UART module 0 Data Set Ready modem output control line.
U0DTR	R3 B13	PH4 (1) PP2 (1)	O	TTL	UART module 0 Data Terminal Ready modem status input signal.
U0RI	T2 W16 N18	PH5 (1) PK7 (1) PM7 (1)	I	TTL	UART module 0 Ring Indicator modem status input signal.
U0RTS	B6 B7 K15 P4	PB5 (1) PE7 (1) PG5 (1) PH0 (1)	O	TTL	UART module 0 Request to Send modem flow control output signal.
U0Rx	V3	PA0 (1)	I	TTL	UART module 0 receive.
U0Tx	W3	PA1 (1)	O	TTL	UART module 0 transmit.
U1CTS	B11 C12	PN1 (1) PP3 (1)	I	TTL	UART module 1 Clear To Send modem flow control input signal.
U1DCD	G1 A11 B8	PE2 (1) PN2 (1) PP6 (1)	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
U1DSR	H2 B10 B14	PE1 (1) PN3 (1) PS2 (1)	I	TTL	UART module 1 Data Set Ready modem output control line.
U1DTR	G2 A10 U15	PE3 (1) PN4 (1) PQ6 (1)	O	TTL	UART module 1 Data Terminal Ready modem status input signal.
U1RI	A5 B9 M3	PE4 (1) PN5 (1) PQ7 (1)	I	TTL	UART module 1 Ring Indicator modem status input signal.
U1RTS	H3 C10 U12	PE0 (1) PN0 (1) PN7 (1)	O	TTL	UART module 1 Request to Send modem flow control output line.
U1Rx	A16 A13 P2	PB0 (1) PQ4 (1) PR5 (1)	I	TTL	UART module 1 receive.
U1Tx	B16 W12 W9	PB1 (1) PQ5 (1) PR6 (1)	O	TTL	UART module 1 transmit.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
U2CTS	B2 F16 B10	PD7 (1) PJ3 (1) PN3 (2)	I	TTL	UART module 2 Clear To Send modem flow control input signal.
U2RTS	B3 H17 A11	PD6 (1) PJ2 (1) PN2 (2)	O	TTL	UART module 2 Request to Send modem flow control output line.
U2Rx	V5 A4	PA6 (1) PD4 (1)	I	TTL	UART module 2 receive.
U2Tx	R7 B4	PA7 (1) PD5 (1)	O	TTL	UART module 2 transmit.
U3CTS	E17 B9 B12	PJ5 (1) PN5 (2) PP5 (1)	I	TTL	UART module 3 Clear To Send modem flow control input signal.
U3RTS	F18 A10 D8	PJ4 (1) PN4 (2) PP4 (1)	O	TTL	UART module 3 Request to Send modem flow control output line.
U3Rx	V4 C8	PA4 (1) PJ0 (1)	I	TTL	UART module 3 receive.
U3Tx	W4 E7	PA5 (1) PJ1 (1)	O	TTL	UART module 3 transmit.
U4CTS	K5 K2 U12	PJ7 (1) PK3 (1) PN7 (2)	I	TTL	UART module 4 Clear To Send modem flow control input signal.
U4RTS	N1 K1 T12	PJ6 (1) PK2 (1) PN6 (2)	O	TTL	UART module 4 Request to Send modem flow control output line.
U4Rx	T6 J1 N4	PA2 (1) PK0 (1) PR1 (1)	I	TTL	UART module 4 receive.
U4Tx	U5 J2 N5	PA3 (1) PK1 (1) PR0 (1)	O	TTL	UART module 4 transmit.
U5Rx	L2 U2	PC6 (1) PH6 (1)	I	TTL	UART module 5 receive.
U5Tx	K3 V2	PC7 (1) PH7 (1)	O	TTL	UART module 5 transmit.
U6Rx	D6	PP0 (1)	I	TTL	UART module 6 receive.
U6Tx	D7	PP1 (1)	O	TTL	UART module 6 transmit.
U7Rx	M2 U2	PC4 (1) PH6 (2)	I	TTL	UART module 7 receive.
U7Tx	M1 V2	PC5 (1) PH7 (2)	O	TTL	UART module 7 transmit.
USB0CLK	B17	PB3 (14)	O	TTL	60-MHz clock to the external PHY.
USB0D0	G16	PL0 (14)	I/O	TTL	USB data 0.
USB0D1	H19	PL1 (14)	I/O	TTL	USB data 1.
USB0D2	G18	PL2 (14)	I/O	TTL	USB data 2.
USB0D3	J18	PL3 (14)	I/O	TTL	USB data 3.
USB0D4	H18	PL4 (14)	I/O	TTL	USB data 4.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
USB0D5	G19	PL5 (14)	I/O	TTL	USB data 5.
USB0D6	B12	PP5 (14)	I/O	TTL	USB data 6.
USB0D7	D8	PP4 (14)	I/O	TTL	USB data 7.
USB0DIR	C12	PP3 (14)	O	TTL	Indicates that the external PHY is able to accept data from the USB controller.
USB0DM	B18	PL7	I/O	Analog	Bidirectional differential data pin (D- per USB specification) for USB0.
USB0DP	C18	PL6	I/O	Analog	Bidirectional differential data pin (D+ per USB specification) for USB0.
USB0EPEN	V5 R7 B3	PA6 (5) PA7 (11) PD6 (5)	O	TTL	Optionally used in Host mode to control an external power source to supply power to the USB bus.
USB0ID	A16	PB0	I	Analog	This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side).
USB0NXT	B13	PP2 (14)	O	TTL	Asserted by the external PHY to throttle all data types.
USB0PFLT	R7 B2	PA7 (5) PD7 (5)	I	TTL	Optionally used in Host mode by an external power source to indicate an error state by that power source.
USB0STP	A17	PB2 (14)	O	TTL	Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.
USB0VBUS	B16	PB1	I/O	Analog	This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.
VBAT	P19	fixed	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
VDD	G10 H9 J8 J9 J10 K7 K8 K11 N16 P17 K12 L10 L11 L12 M11 M12 P10	fixed	-	Power	Positive supply for I/O and some logic.

Table 31-3. Signals by Signal Name (*continued*)

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
VDDA	F3	fixed	-	Power	The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation.
VDDC	H16 E10	fixed	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 32-15 on page 2112 .
VREFA+	F4	fixed	-	Analog	A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value . The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 32-44 on page 2134.
VREFA-	G5	fixed	-	Analog	A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 32-44 on page 2134.
WAKE	U18	fixed	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
XOSC0	T18	fixed	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
XOSC1	T19	fixed	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.

31.3 Signals by Function, Except for GPIO

Table 31-4. Signals by Function, Except for GPIO

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
1-Wire	OWALT	K15 B12	I/O	TTL	1-Wire Optional 2nd signal to be used as output.
	OWIRE	G2 K17 V12 U14 D8 A8	I/O	TTL	1-Wire Single Bus Pin. This signal is input only if 1-Wire Alternate Output is enabled.

Table 31-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
ADC	AIN0	G2	I	Analog	Analog-to-digital converter input 0.
	AIN1	G1	I	Analog	Analog-to-digital converter input 1.
	AIN2	H2	I	Analog	Analog-to-digital converter input 2.
	AIN3	H3	I	Analog	Analog-to-digital converter input 3.
	AIN4	B2	I	Analog	Analog-to-digital converter input 4.
	AIN5	B3	I	Analog	Analog-to-digital converter input 5.
	AIN6	B4	I	Analog	Analog-to-digital converter input 6.
	AIN7	A4	I	Analog	Analog-to-digital converter input 7.
	AIN8	B5	I	Analog	Analog-to-digital converter input 8.
	AIN9	A5	I	Analog	Analog-to-digital converter input 9.
	AIN10	C6	I	Analog	Analog-to-digital converter input 10.
	AIN11	B6	I	Analog	Analog-to-digital converter input 11.
	AIN12	D1	I	Analog	Analog-to-digital converter input 12.
	AIN13	D2	I	Analog	Analog-to-digital converter input 13.
	AIN14	C1	I	Analog	Analog-to-digital converter input 14.
	AIN15	C2	I	Analog	Analog-to-digital converter input 15.
	AIN16	J1	I	Analog	Analog-to-digital converter input 16.
	AIN17	J2	I	Analog	Analog-to-digital converter input 17.
	AIN18	K1	I	Analog	Analog-to-digital converter input 18.
	AIN19	K2	I	Analog	Analog-to-digital converter input 19.
	AIN20	A7	I	Analog	Analog-to-digital converter input 20.
	AIN21	B7	I	Analog	Analog-to-digital converter input 21.
	AIN22	A8	I	Analog	Analog-to-digital converter input 22.
	AIN23	B8	I	Analog	Analog-to-digital converter input 23.
	VREFA+	F4	-	Analog	A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AIN _n signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 32-44 on page 2134.
	VREFA-	G5	-	Analog	A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AIN _n signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AIN _n signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 32-44 on page 2134.

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
Analog Comparators	C0+	L2	I	Analog	Analog comparator 0 positive input.
	C0-	K3	I	Analog	Analog comparator 0 negative input.
	C0o	C2 G18	O	TTL	Analog comparator 0 output.
	C1+	M1	I	Analog	Analog comparator 1 positive input.
	C1-	M2	I	Analog	Analog comparator 1 negative input.
	C1o	C1 J18	O	TTL	Analog comparator 1 output.
	C2+	D6	I	Analog	Analog comparator 2 positive input.
	C2-	D7	I	Analog	Analog comparator 2 negative input.
	C2o	D2	O	TTL	Analog comparator 2 output.
Controller Area Network	CAN0Rx	V3 W10	I	TTL	CAN module 0 receive.
	CAN0Tx	W3 V10	O	TTL	CAN module 0 transmit.
	CAN1Rx	A16 E18	I	TTL	CAN module 1 receive.
	CAN1Tx	B16 F17	O	TTL	CAN module 1 transmit.
Core	TRCLK	T7	O	TTL	Trace clock.
	TRD0	W6	O	TTL	Trace data 0.
	TRD1	V6	O	TTL	Trace data 1.
	TRD2	U6	O	TTL	Trace data 2.
	TRD3	V7	O	TTL	Trace data 3.

Table 31-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
Ethernet	EN0COL	N18	I	TTL	Ethernet 0 Collision Detect.
	EN0CRS	N19	I	TTL	Ethernet 0 Carrier Sense.
	ENOINTRN	U19 D6	I	TTL	Ethernet 0 Interrupt from the Ethernet PHY.
	ENOLED0	U6 U19	O	TTL	Ethernet 0 LED 0.
	ENOLED1	V7 V16	O	TTL	Ethernet 0 LED 1.
	ENOLED2	V6 V17	O	TTL	Ethernet 0 LED 2.
	EN0MDC	A17 W6	O	TTL	Ethernet 0 Management Data Clock.
	EN0MDIO	B17 T7	I/O	TTL	Ethernet 0 Management Data Input/Output signal.
	EN0PPS	N15 T2 C8	O	TTL	Ethernet 0 Pulse-Per-Second (PPS) Output.
	EN0REF_CLK	M18	I/O	TTL	Ethernet 0 Reference Clock.
	EN0RXCK	V5	I	TTL	Ethernet 0 Receive Clock.
	EN0RXD0	W12 W10	I	TTL	Ethernet 0 Receive Data 0.
	EN0RXD1	U15 V10	I	TTL	Ethernet 0 Receive Data 1.
	EN0RXD2	V17	I	TTL	Ethernet 0 Receive Data 2.
	EN0RXD3	U19	I	TTL	Ethernet 0 Receive Data 3.
	EN0RXDV	U14 R13	I	TTL	Ethernet 0 Receive Data Valid.
	EN0RXER	V12 U10	I	TTL	Ethernet 0 Receive Error.
	EN0RXIN	V13	I/O	TTL	Ethernet PHY negative receive differential input.
	EN0RXIP	W13	I/O	TTL	Ethernet PHY positive receive differential input.
	EN0TXCK	V11	I	TTL	Ethernet 0 Transmit Clock.
	EN0TXD0	K17 V9	O	TTL	Ethernet 0 Transmit Data 0.
	EN0TXD1	K15 T13	O	TTL	Ethernet 0 Transmit Data 1.
	EN0TXD2	V16	O	TTL	Ethernet 0 Transmit Data 2.
	EN0TXD3	W16	O	TTL	Ethernet 0 Transmit Data 3.
	EN0TXEN	M16 R10	O	TTL	Ethernet 0 Transmit Enable.
	EN0TXER	T12	O	TTL	Ethernet 0 transmit error.
	EN0TXON	V14	I/O	TTL	Ethernet PHY negative transmit differential output.
	EN0TXOP	V15	I/O	TTL	Ethernet PHY positive transmit differential output.
	RBIAS	W15	O	Analog	4.87-kΩ resistor (1% precision) for Ethernet PHY.

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
External Peripheral Interface	EPIOS0	P4 J1	I/O	TTL	EPI module 0 signal 0.
	EPIOS1	R2 J2	I/O	TTL	EPI module 0 signal 1.
	EPIOS2	R1 K1	I/O	TTL	EPI module 0 signal 2.
	EPIOS3	T1 K2	I/O	TTL	EPI module 0 signal 3.
	EPIOS4	K3	I/O	TTL	EPI module 0 signal 4.
	EPIOS5	L2	I/O	TTL	EPI module 0 signal 5.
	EPIOS6	M1	I/O	TTL	EPI module 0 signal 6.
	EPIOS7	M2	I/O	TTL	EPI module 0 signal 7.
	EPIOS8	V5	I/O	TTL	EPI module 0 signal 8.
	EPIOS9	R7	I/O	TTL	EPI module 0 signal 9.

	EPIOS18	G18	I/O	TTL	EPI module 0 signal 18.
	EPIOS19	J18	I/O	TTL	EPI module 0 signal 19.
	EPIOS20	E3	I/O	TTL	EPI module 0 signal 20.
	EPIOS21	E2	I/O	TTL	EPI module 0 signal 21.
	EPIOS22	H4	I/O	TTL	EPI module 0 signal 22.
	EPIOS23	M4	I/O	TTL	EPI module 0 signal 23.
	EPIOS24	W16	I/O	TTL	EPI module 0 signal 24.
	EPIOS25	V16	I/O	TTL	EPI module 0 signal 25.
	EPIOS26	H18	I/O	TTL	EPI module 0 signal 26.
	EPIOS27	A17	I/O	TTL	EPI module 0 signal 27.
	EPIOS28	B17	I/O	TTL	EPI module 0 signal 28.
	EPIOS29	A11 B13	I/O	TTL	EPI module 0 signal 29.
	EPIOS30	B10 C12	I/O	TTL	EPI module 0 signal 30.
	EPIOS31	V17	I/O	TTL	EPI module 0 signal 31.
	EPIOS32	U19	I/O	TTL	EPI module 0 signal 32.
	EPIOS33	G19	I/O	TTL	EPI module 0 signal 33.
	EPIOS34	A10	I/O	TTL	EPI module 0 signal 34.
	EPIOS35	B9	I/O	TTL	EPI module 0 signal 35.

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
General-Purpose Timers	T0CCP0	V3 C2 H18 P3	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 0.
	T0CCP1	W3 C1 G19 P2	I/O	TTL	16/32-Bit Timer 0 Capture/Compare/PWM 1.
	T1CCP0	T6 D2 C18 W9	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 0.
	T1CCP1	U5 D1 B18 R10	I/O	TTL	16/32-Bit Timer 1 Capture/Compare/PWM 1.
	T2CCP0	V4 K18 D12	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 0.
	T2CCP1	W4 K19 D13	I/O	TTL	16/32-Bit Timer 2 Capture/Compare/PWM 1.
	T3CCP0	V5 A4 L18 B14	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 0.
	T3CCP1	R7 B4 L19 A14	I/O	TTL	16/32-Bit Timer 3 Capture/Compare/PWM 1.
	T4CCP0	A16 B3 M18 V9	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 0.
	T4CCP1	B16 B2 G15 T13	I/O	TTL	16/32-Bit Timer 4 Capture/Compare/PWM 1.
	T5CCP0	A17 N19 U10	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 0.
	T5CCP1	B17 N18 R13	I/O	TTL	16/32-Bit Timer 5 Capture/Compare/PWM 1.
	T6CCP0	F2 D6 E3 W10	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 0.
	T6CCP1	F1 D7 E2 V10	I/O	TTL	16/32-Bit Timer 6 Capture/Compare/PWM 1.
	T7CCP0		I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 0.

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
		M2 H4 E18			
	T7CCP1	M1 M4 F17	I/O	TTL	16/32-Bit Timer 7 Capture/Compare/PWM 1.
Hibernate	GNDX	R18	-	Power	GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.
	HIB	M17	O	TTL	An output that indicates the processor is in Hibernate mode.
	RTCCLK	M1 W16 C12	O	TTL	Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset.
	TMPR0	N18	I/O	TTL	Tamper signal 0.
	TMPR1	N19	I/O	TTL	Tamper signal 1.
	TMPR2	G15	I/O	TTL	Tamper signal 2.
	TMPR3	M18	I/O	TTL	Tamper signal 3.
	VBAT	P19	-	Power	Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.
	WAKE	U18	I	TTL	An external input that brings the processor out of Hibernate mode when asserted.
	XOSC0	T18	I	Analog	Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.
	XOSC1	T19	O	Analog	Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.

Table 31-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
I2C	I2C0SCL	A17	I/O	OD	I ² C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C0SDA	B17	I/O	OD	I ² C module 0 data.
	I2C1SCL	N15 N5	I/O	OD	I ² C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C1SDA	T14 N4	I/O	OD	I ² C module 1 data.
	I2C2SCL	V11 H19 B9 B12 N2	I/O	OD	I ² C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C2SDA	M16 G16 A10 B8 V8	I/O	OD	I ² C module 2 data.
	I2C3SCL	K17 U19 P3	I/O	OD	I ² C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C3SDA	K15 V17 P2	I/O	OD	I ² C module 3 data.
	I2C4SCL	V12 V16 W9	I/O	OD	I ² C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C4SDA	U14 W16 R10	I/O	OD	I ² C module 4 data.
	I2C5SCL	A16 C6	I/O	OD	I ² C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C5SDA	B16 B6	I/O	OD	I ² C module 5 data.
	I2C6SCL	V5 F2	I/O	OD	I ² C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C6SDA	R7 F1	I/O	OD	I ² C module 6 data.
	I2C7SCL	V4 C2	I/O	OD	I ² C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C7SDA	W4 C1	I/O	OD	I ² C module 7 data.
	I2C8SCL	T6 D2	I/O	OD	I ² C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C8SDA	U5 D1	I/O	OD	I ² C module 8 data.

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
	I2C9SCL	V3 A7	I/O	OD	I ² C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.
	I2C9SDA	W3 B7	I/O	OD	I ² C module 9 data.
JTAG/SWD/SWO	SWCLK	B15	I	TTL	JTAG/SWD CLK.
	SWDIO	C15	I/O	TTL	JTAG TMS and SWDIO.
	SWO	C14	O	TTL	JTAG TDO and SWO.
	TCK	B15	I	TTL	JTAG/SWD CLK.
	TDI	D14	I	TTL	JTAG TDI.
	TDO	C14	O	TTL	JTAG TDO and SWO.
	TMS	C15	I	TTL	JTAG TMS and SWDIO.

Table 31-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
LCD	LCDAC	N1	O	TTL	LCD AC bias or latch enable in Raster mode; Primary chip select (CS0)/Primary Enable (E0) in LIDD MPU/Hitachi mode
	LCDCP	N5	O	TTL	LCD Pixel Clock in Raster mode; read strobe or read/write strobe in LIDD mode
	LCDDATA00	P3	I/O	TTL	LCD Data Pin 0 input/output.
	LCDDATA01	P2	I/O	TTL	LCD Data Pin 1 input/output.
	LCDDATA02	U8	I/O	TTL	LCD Data Pin 2 input/output.
	LCDDATA03	V8	I/O	TTL	LCD Data Pin 3 input/output.
	LCDDATA04	W9	I/O	TTL	LCD Data Pin 4 input/output.
	LCDDATA05	R10	I/O	TTL	LCD Data Pin 5 input/output.
	LCDDATA06	V9	I/O	TTL	LCD Data Pin 6 input/output.
	LCDDATA07	T13	I/O	TTL	LCD Data Pin 7 input/output.
	LCDDATA08	U10	I/O	TTL	LCD Data Pin 8 input/output.
	LCDDATA09	R13	I/O	TTL	LCD Data Pin 9 input/output.
	LCDDATA10	W10	I/O	TTL	LCD Data Pin 10 input/output.
	LCDDATA11	V10	I/O	TTL	LCD Data Pin 11 input/output.
	LCDDATA12	U12	I/O	TTL	LCD Data Pin 12 input/output.
	LCDDATA13	T12	I/O	TTL	LCD Data Pin 13 input/output.
	LCDDATA14	H17	I/O	TTL	LCD Data Pin 14 input/output.
	LCDDATA15	F16	I/O	TTL	LCD Data Pin 15 input/output.
	LCDDATA16	F18	O	TTL	LCD Data Pin 16 output.
	LCDDATA17	E17	O	TTL	LCD Data Pin 17 output.
	LCDDATA18	E18	O	TTL	LCD Data Pin 18 output.
	LCDDATA19	F17	O	TTL	LCD Data Pin 19 output.
	LCDDATA20	D12	O	TTL	LCD Data Pin 20 output.
	LCDDATA21	D13	O	TTL	LCD Data Pin 21 output.
	LCDDATA22	B14	O	TTL	LCD Data Pin 22 output.
	LCDDATA23	A14	O	TTL	LCD Data Pin 23 output.
	LCDFP	N4	O	TTL	LCD Frame Clock or VSYNC in Raster mode; Address Latch Enable in LIDD mode
	LCDLP	N2	O	TTL	LCD Line Clock or HSYNC in Raster mode; Write Strobe or Direction bit in LIDD mode
	LCDMCLK	T8	O	TTL	LCD Memory Clock/Secondary chip Select (CS1)/Secondary Enable (E1) in LIDD Synchronous/Async MPU/Hitachi mode

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
PWM	M0FAULT0	V7 D12	I	TTL	Motion Control Module 0 PWM Fault 0.
	M0FAULT1	V16 D13	I	TTL	Motion Control Module 0 PWM Fault 1.
	M0FAULT2	W16 B14	I	TTL	Motion Control Module 0 PWM Fault 2.
	M0FAULT3	G16 A14	I	TTL	Motion Control Module 0 PWM Fault 3.
	M0PWM0	U6 N5	O	TTL	Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.
	M0PWM1	V6 N4	O	TTL	Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.
	M0PWM2	W6 N2	O	TTL	Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.
	M0PWM3	T7 V8	O	TTL	Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.
	M0PWM4	N15 P3	O	TTL	Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.
	M0PWM5	T14 P2	O	TTL	Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.
	M0PWM6	U19 W9	O	TTL	Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.
	M0PWM7	V17 R10	O	TTL	Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.

Table 31-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
Power	GND	F10 H10 H11 H12 J11 J12 K6 K9 P16 K10 R17 K13 K14 L8 L9 M8 M9 M10 N10 A1 A2 B1 V1 W1 W2 A18 A19 B19	-	Power	Ground reference for logic and I/O pins.
	GNDA	G4	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
	VDD	G10 H9 J8 J9 J10 K7 K8 K11 N16 P17 K12 L10 L11 L12 M11 M12 P10	-	Power	Positive supply for I/O and some logic.
	VDDA	F3	-	Power	The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation.
	VDDC	H16 E10	-	Power	

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
					Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 32-15 on page 2112 .
QEI	IDX0	J18 U10	I	TTL	QEI module 0 index.
	PhA0	H19 V9	I	TTL	QEI module 0 phase A.
	PhB0	G18 T13	I	TTL	QEI module 0 phase B.

Table 31-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
SSI	SSI0Clk	T6	I/O	TTL	SSI module 0 clock
	SSI0Fss	U5	I/O	TTL	SSI module 0 frame signal
	SSI0XDAT0	V4	I/O	TTL	SSI Module 0 Bi-directional Data Pin 0 (SSI0TX in Legacy SSI Mode).
	SSI0XDAT1	W4	I/O	TTL	SSI Module 0 Bi-directional Data Pin 1 (SSI0RX in Legacy SSI Mode).
	SSI0XDAT2	V5	I/O	TTL	SSI Module 0 Bi-directional Data Pin 2.
	SSI0XDAT3	R7	I/O	TTL	SSI Module 0 Bi-directional Data Pin 3.
	SSI1Clk	B6	I/O	TTL	SSI module 1 clock.
	SSI1Fss	C6	I/O	TTL	SSI module 1 frame signal.
	SSI1XDAT0	A5	I/O	TTL	SSI Module 1 Bi-directional Data Pin 0 (SSI1TX in Legacy SSI Mode).
	SSI1XDAT1	B5	I/O	TTL	SSI Module 1 Bi-directional Data Pin 1 (SSI1RX in Legacy SSI Mode).
	SSI1XDAT2	A4	I/O	TTL	SSI Module 1 Bi-directional Data Pin 2.
	SSI1XDAT3	B4	I/O	TTL	SSI Module 1 Bi-directional Data Pin 3.
	SSI2Clk	D1 U14	I/O	TTL	SSI module 2 clock.
	SSI2Fss	D2 V12	I/O	TTL	SSI module 2 frame signal.
	SSI2XDAT0	C1 K15	I/O	TTL	SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode).
	SSI2XDAT1	C2 K17	I/O	TTL	SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode).
	SSI2XDAT2	B2 M16	I/O	TTL	SSI Module 2 Bi-directional Data Pin 2.
	SSI2XDAT3	B3 V11	I/O	TTL	SSI Module 2 Bi-directional Data Pin 3.
	SSI3Clk	T7 E3	I/O	TTL	SSI module 3 clock.
	SSI3Fss	W6 E2	I/O	TTL	SSI module 3 frame signal.
	SSI3XDAT0	V6 H4	I/O	TTL	SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode).
	SSI3XDAT1	U6 M4	I/O	TTL	SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode).
	SSI3XDAT2	V7 D6	I/O	TTL	SSI Module 3 Bi-directional Data Pin 2.
	SSI3XDAT3	W7 D7	I/O	TTL	SSI Module 3 Bi-directional Data Pin 3.

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
System Control & Clocks	DIVSCLK	A13	O	TTL	An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock.
	GNDX2	D18	-	Power	GND for the MOSC. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.
	NMI	B2 B7	I	TTL	Non-maskable interrupt.
	OSC0	E19	I	Analog	Main oscillator crystal input or an external clock reference input.
	OSC1	D19	O	Analog	Main oscillator crystal output. Leave unconnected when using a single-ended clock source.
	$\overline{\text{RST}}$	P18	I	TTL	System reset input.

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
UART	U0CTS	C6 A7 K17 R2 M18	I	TTL	UART module 0 Clear To Send modem flow control input signal.
	U0DCD	R1 G15 C12	I	TTL	UART module 0 Data Carrier Detect modem status input signal.
	U0DSR	T1 N19 D8	I	TTL	UART module 0 Data Set Ready modem output control line.
	U0DTR	R3 B13	O	TTL	UART module 0 Data Terminal Ready modem status input signal.
	U0RI	T2 W16 N18	I	TTL	UART module 0 Ring Indicator modem status input signal.
	U0RTS	B6 B7 K15 P4	O	TTL	UART module 0 Request to Send modem flow control output signal.
	U0Rx	V3	I	TTL	UART module 0 receive.
	U0Tx	W3	O	TTL	UART module 0 transmit.
	U1CTS	B11 C12	I	TTL	UART module 1 Clear To Send modem flow control input signal.
	U1DCD	G1 A11 B8	I	TTL	UART module 1 Data Carrier Detect modem status input signal.
	U1DSR	H2 B10 B14	I	TTL	UART module 1 Data Set Ready modem output control line.
	U1DTR	G2 A10 U15	O	TTL	UART module 1 Data Terminal Ready modem status input signal.
	U1RI	A5 B9 M3	I	TTL	UART module 1 Ring Indicator modem status input signal.
	U1RTS	H3 C10 U12	O	TTL	UART module 1 Request to Send modem flow control output line.
	U1Rx	A16 A13 P2	I	TTL	UART module 1 receive.
	U1Tx	B16 W12 W9	O	TTL	UART module 1 transmit.
USART	U2CTS	B2 F16 B10	I	TTL	UART module 2 Clear To Send modem flow control input signal.
	U2RTS	B3 H17 A11	O	TTL	UART module 2 Request to Send modem flow control output line.
	U2Rx		I	TTL	UART module 2 receive.

Table 31-4. Signals by Function, Except for GPIO (*continued*)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
		V5 A4			
	U2Tx	R7 B4	O	TTL	UART module 2 transmit.
	U3CTS	E17 B9 B12	I	TTL	UART module 3 Clear To Send modem flow control input signal.
	U3RTS	F18 A10 D8	O	TTL	UART module 3 Request to Send modem flow control output line.
	U3Rx	V4 C8	I	TTL	UART module 3 receive.
	U3Tx	W4 E7	O	TTL	UART module 3 transmit.
	U4CTS	K5 K2 U12	I	TTL	UART module 4 Clear To Send modem flow control input signal.
	U4RTS	N1 K1 T12	O	TTL	UART module 4 Request to Send modem flow control output line.
	U4Rx	T6 J1 N4	I	TTL	UART module 4 receive.
	U4Tx	U5 J2 N5	O	TTL	UART module 4 transmit.
	U5Rx	L2 U2	I	TTL	UART module 5 receive.
	U5Tx	K3 V2	O	TTL	UART module 5 transmit.
	U6Rx	D6	I	TTL	UART module 6 receive.
	U6Tx	D7	O	TTL	UART module 6 transmit.
	U7Rx	M2 U2	I	TTL	UART module 7 receive.
	U7Tx	M1 V2	O	TTL	UART module 7 transmit.

Table 31-4. Signals by Function, Except for GPIO (continued)

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
USB	USB0CLK	B17	O	TTL	60-MHz clock to the external PHY.
	USB0D0	G16	I/O	TTL	USB data 0.
	USB0D1	H19	I/O	TTL	USB data 1.
	USB0D2	G18	I/O	TTL	USB data 2.
	USB0D3	J18	I/O	TTL	USB data 3.
	USB0D4	H18	I/O	TTL	USB data 4.
	USB0D5	G19	I/O	TTL	USB data 5.
	USB0D6	B12	I/O	TTL	USB data 6.
	USB0D7	D8	I/O	TTL	USB data 7.
	USB0DIR	C12	O	TTL	Indicates that the external PHY is able to accept data from the USB controller.
	USB0DM	B18	I/O	Analog	Bidirectional differential data pin (D- per USB specification) for USB0.
	USB0DP	C18	I/O	Analog	Bidirectional differential data pin (D+ per USB specification) for USB0.
	USB0EPEN	V5 R7 B3	O	TTL	Optionally used in Host mode to control an external power source to supply power to the USB bus.
	USB0ID	A16	I	Analog	This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side).
	USB0NXT	B13	O	TTL	Asserted by the external PHY to throttle all data types.
	USB0PFLT	R7 B2	I	TTL	Optionally used in Host mode by an external power source to indicate an error state by that power source.
	USB0STP	A17	O	TTL	Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.
	USB0VBUS	B16	I/O	Analog	This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.

31.4 GPIO Pins and Alternate Functions

Table 31-5. GPIO Pins and Alternate Functions

IO	Pin	Analog or Special Function ^a	Digital Function (GPIOCTL PMCx Bit Field Encoding) ^b

a. The TMPRn signals are digital signals enabled and configured by the Hibernation module. All other signals listed in this column are analog signals.

b. The digital signals that are shaded gray are the power-on default values for the corresponding GPIO pin. Encodings 9, 10, and 12 are not used on this device.

31.6 Connections for Unused Signals

Table 31-7 on page 2097 show how to handle signals for functions that are not used in a particular system implementation for devices that are in a 212-ball BGA package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

Table 31-7. Connections for Unused Signals (212-Ball BGA)

Function	Signal Name	Pin Number	Acceptable Practice	Preferred Practice
ADC	VREFA+	F4	VDDA	VDDA
	VREFA-	G5	GND	GND
Ethernet	EN0RXIN	V13	NC	NC
	EN0RXIP	W13	NC	NC
	EN0TXON	V14	NC	NC
	EN0TXOP	V15	NC	NC
	RBIAS	W15	Connect to ground through 4.87K resistor	NC ^a
GPIO	PA1(UART0TX)	W3	NC	GND ^b
	PA4 (SSI0XDATA0)	V4	NC	GND ^c
	All unused GPIOs	-	NC	GND

Table 31-7. Connections for Unused Signals (212-Ball BGA) (continued)

Function	Signal Name	Pin Number	Acceptable Practice	Preferred Practice
Hibernate	GNDX	R18	GND	GND
	HTB	M17	NC	NC
	VBAT	P19	NC	VDD
	WAKE	U18	NC	GND
	XOSC0	T18	NC	GND
	XOSC1	T19	NC	NC
No Connects	NC	See NC pin numbers in Table 31-3 on page 2052	NC	NC
System Control	GNDX2	D18	GND	GND
	OSC0	E19	NC	GND
	OSC1	D19	NC	NC
	RST	P18	VDD	Pull up as shown in Figure 5-1 on page 234
USB	USB0DM / PL7	B18	NC	Pull-down to GND with 1K resistor ^d
	USB0DP / PL6	C18	NC	Pull-down to GND with 1K resistor ^d

- a. The internal Ethernet PHY should not be enabled when R_{BIAS} is not connected. The ROM boot loader will enable the internal Ethernet PHY if no code is present in the flash and a 24-25 Mhz crystal is attached to the OSC0/OSC1 pins.
- b. PA1 (UART0TX) may be enabled as an output by the ROM boot loader if no code is present in the flash and PA0 (UART0RX) receives a valid boot signature. Ensure that this condition will not occur if PA1 is to be connected directly to GND.
- c. PA4 (SSI0XDATO) may be enabled as an output by the ROM boot loader if no code is present in the flash and the SSI0X (PA2, PA3, PA5) receives a valid boot signature. Ensure that this condition will not occur if PA4 is to be connected directly to GND.
- d. The ROM boot loader may configure these pins as USB pins if no code is present in the flash therefore they should not be directly connected to ground.

32 Electrical Characteristics

32.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device. Device reliability may be adversely affected by exposure to absolute-maximum ratings for extended periods.

Note: The device is not guaranteed to operate properly at the maximum ratings.

Table 32-1. Absolute Maximum Ratings

Parameter	Parameter Name ^a	Value		Unit
		Min	Max	
V_{DD}	V_{DD} supply voltage	0	4	V
V_{DDA}	V_{DDA} supply voltage	0	4	V
V_{BAT}	V_{BAT} battery supply voltage	0	4	V
V_{BATRMP}	V_{BAT} battery supply voltage ramp time	0	0.7	V/ μ s
V_{IN_GPIO}	Input voltage ^b	-0.3	4	V
$I_{GPIOMAX}$	Maximum current per output pin	-	64	mA
T_S	Unpowered storage temperature range	-65	150	°C
T_{JMAX}	Maximum junction temperature	-	125	°C

a. Voltages are measured with respect to GND.

b. Applies to static and dynamic signals including overshoot.

Important: This device contains circuitry to protect the I/Os against damage due to high-static voltages; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (see “Connections for Unused Signals” on page 2097).

Table 32-2. ESD Absolute Maximum Ratings

Parameter	Parameter Name	Min	Nom	Max	Unit
Component-Level ESD Stress Voltage ^a	V_{ESDHBM} ^b	-	-	2.0	kV
	V_{ESDCDM} ^c	-	-	500	V

a. Electrostatic discharge (ESD) is used to measure device sensitivity/immunity to damage caused by electrostatic discharges in device.

b. All pins are HBM compliant to 2 kV for all combinations as per JESD22-A114F, except for the following stress combinations:

- The GPIO pins PM4, PM5, PM6, and PM7 to other pins.

These exceptions are compliant to 500 V and do not require any special handling beyond typical ESD control procedures during assembly operations per JEDEC publication JEP155. Note that these pins do meet the 500 V CDM specification.

c. Level listed is the passing level per EIA-JEDEC JESD22-C101E. JEDEC document JEP157 states that 250 V CDM allows safe manufacturing with a standard ESD control process.

32.2 Operating Characteristics

Table 32-3. Temperature Characteristics

Characteristic	Symbol	Value	Unit
Ambient operating temperature range	T_A	-40 to 85 (industrial temperature part) -40 to 105 (extended temperature part)	°C
Junction operating temperature range	T_J	-40 to 105 (industrial temperature part) -40 to 125 (extended temperature part)	°C

Table 32-4. 212 BGA Power Dissipation^{ab}

Parameter	Parameter Name	T_A	T_J	Min	Max	Unit
P_{DI}	Industrial temperature device power dissipation	85 °C (industrial temperature part)	125 °C (industrial temperature part)	-	1018	mW
P_{DE}	Extended temperature device power dissipation	105 °C (extended temperature part)	125 °C (extended temperature part)	-	509	mW

- a. If the device exceeds the power dissipation value shown, then modifications such as heat sinks or fans must be used to conform to the limits shown.
- b. A larger power dissipation allowance can be achieved by lowering T_A as long as T_{JMAX} shown in Table 32-1 on page 2099 is not exceeded.

Table 32-5. Thermal Characteristics^a

Characteristic	Symbol	Value	Unit
Thermal resistance (junction to ambient) ^b	Θ_{JA}	39.3	°C/W
Thermal resistance (junction to board) ^b	Θ_{JB}	18.6	°C/W
Thermal resistance (junction to case) ^b	Θ_{JC}	12.9	°C/W
Thermal metric (junction to top of package)	Ψ_{JT}	0.2	°C/W
Thermal metric (junction to board)	Ψ_{JB}	18.4	°C/W
Junction temperature formula	T_J	$T_C + (P \cdot \Psi_{JT})^c$ $T_{PCB} + (P \cdot \Psi_{JB})^d$ $T_A + (P \cdot \Theta_{JA})^e$ $T_B + (P \cdot \Theta_{JB})^{fg}$	°C

- a. For more details about thermal metrics and definitions, see the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)).
- b. Junction to ambient thermal resistance (Θ_{JA}), junction to board thermal resistance (Θ_{JB}), and junction to case thermal resistance (Θ_{JC}) numbers are determined by a package simulator.
- c. T_C is the case temperature and P is the device power consumption.
- d. T_{PCB} is the temperature of the board acquired by following the steps listed in the EAI/JESD 51-8 standard summarized in the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)). P is the device power consumption.
- e. Because Θ_{JA} is highly variable and based on factors such as board design, chip/pad size, altitude, and external ambient temperature, it is recommended that equations containing Ψ_{JT} and Ψ_{JB} be used for best results.
- f. T_B is temperature of the board.

g. Θ_{JB} is not a pure reflection of the internal resistance of the package because it includes the resistance of the testing board and environment. It is recommended that equations containing Ψ_{JT} and Ψ_{JB} be used for best results.

32.3 Recommended Operating Conditions

The following sections describe the recommended DC operating conditions and GPIO operating characteristics for the device.

32.3.1 DC Operating Conditions

Table 32-6. Recommended DC Operating Conditions

Parameter	Parameter Name	Min	Nom	Max	Unit
V_{DD}	V_{DD} supply voltage	2.97	3.3	3.63	V
V_{DDA}^a	V_{DDA} supply voltage	2.97	3.3	3.63	V
V_{DDC}	V_{DDC} supply voltage, Run mode	1.14	1.2	1.32	V
V_{DDCDS}	V_{DDC} supply voltage, Deep-sleep mode	0.85	-	0.95	V

a. To ensure proper operation, V_{DDA} must be powered up before V_{DD} if sourced from different supplies, or connected to the same supply as V_{DD} . There is not a restriction on order for powering off.

32.3.2 Recommended GPIO Operating Characteristics

Two types of pads are provided on the device:

- Fast GPIO pads: These pads provide variable, programmable drive strength and optimized voltage output levels.
- Slow GPIO pads: These pads provide 2-mA drive strength and are designed to be sensitive to voltage inputs. The following GPIOs port pins are designed with Slow GPIO Pads:
 - PJ1

All other GPIOs have a fast GPIO pad-type.

Note: Port pins PL6 and PL7 operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**.

Note: Port pins PM[7:4] operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins.

Table 32-7 on page 2101 detail the GPIO operating conditions for these two different pad types.

Table 32-7. Recommended FAST GPIO Pad Operating Conditions

Parameter	Parameter Name	Min	Nom	Max	Unit
V_{IH}	Fast GPIO high-level input voltage	$0.65 * V_{DD}$	-	4	V
I_{IH}	Fast GPIO high-level input current ^a	-	-	300	nA
V_{IL}	Fast GPIO low-level input voltage	0	-	$0.35 * V_{DD}$	V
I_{IL}	Fast GPIO low-level input current ^a	-	-	-200	nA
V_{HYS}	Fast GPIO Input Hysteresis	0.49	-	-	V
V_{OH}	Fast GPIO High-level output voltage	2.4	-	-	V
V_{OL}	Fast GPIO Low-level output voltage	-	-	0.40	V

Table 32-7. Recommended FAST GPIO Pad Operating Conditions (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
I_{OH}	Fast GPIO High-level source current, $V_{OH}=2.4\text{ V}^b$				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA
	10-mA Drive	10.0	-	-	mA
	12-mA Drive	12.0	-	-	mA
I_{OL}	Fast GPIO Low-level sink current, $V_{OL}=0.4\text{ V}^b$				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA
	10-mA Drive	10.0	-	-	mA
	12-mA Drive	12.0	-	-	mA
	12-mA Drive overdriven to 18-mA	18.0	-	-	mA

a. Output/pull-up/pull-down disabled; only input enabled.

b. I_O specifications reflect the maximum current where the corresponding output voltage meets the V_{OH}/V_{OL} thresholds. I_O current can exceed these limits (subject to absolute maximum ratings).**Table 32-8. Recommended Slow GPIO Pad Operating Conditions**

Parameter	Parameter Name	Min	Nom	Max	Unit
V_{IH}	Slow GPIO high-level input voltage	$0.65 * V_{DD}$	-	4	V
I_{IH}	Slow GPIO high-level input current ^a	-	-	4.1	nA
V_{IL}	Slow GPIO low-level input voltage	0	-	$0.35 * V_{DD}$	V
I_{IL}	Slow GPIO low-level input current ^a	-	-	-1	nA
V_{HYS}	Slow GPIO Input Hysteresis	0.49	-	-	V
V_{OH}	Slow GPIO High-level output voltage	2.4	-	-	V
V_{OL}	Slow GPIO Low-level output voltage	-	-	0.4	V
I_{OH}	High-level source current, $V_{OH}=2.4\text{ V}^b$				
	2-mA Drive	2.0	-	-	mA
I_{OL}	Low-level sink current, $V_{OL}=0.4\text{ V}^b$				
	2-mA Drive	2.0	-	-	mA

a. Output/pull-up/pull-down disabled; only input enabled.

b. I_O specifications reflect the maximum current where the corresponding output voltage meets the V_{OH}/V_{OL} thresholds. I_O current can exceed these limits (subject to absolute maximum ratings).

32.3.2.1 GPIO Current Restrictions

Table 32-9. GPIO Current Restrictions^a

Parameter	Parameter Name	Min	Nom	Max	Unit
I_{MAXL}	Cumulative maximum GPIO current per side, left ^b	-	-	110	mA
I_{MAXB}	Cumulative maximum GPIO current per side, bottom ^b	-	-	116	mA
I_{MAXR}	Cumulative maximum GPIO current per side, right ^b	-	-	110	mA

Table 32-9. GPIO Current Restrictions (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
I_{MAXT}	Cumulative maximum GPIO current per side, top ^b	-	-	88	mA

a. Based on design simulations, not tested in production.

b. Sum of sink and source current for GPIOs as shown in Table 32-10 on page 2103.

Table 32-10. Maximum GPIO Package Side Assignments

Side	GPIOs
Left	PB[6-7], PC[4-7], PD[0-3], PE[0-3], PH[0-7], PJ[6-7], PK[0-3], PQ[0-3,7], PR[0-5]
Bottom	PA[0-7], PF[0-7], PG[0-7], PK[4-7], PN[6-7], PR[3,6-7], PQ[5-6], PS[4-7], PT[0-1]
Right	PB[0-3], PJ[2-5], PL[0-5,6-7], PM[0-7], PT[2-3]
Top	PB[4-5], PC[0-3], PD[4-7], PE[4-7], PJ[0-1], PN[0-5], PP[0-7], PQ[4], PS[0-3],

I/O Reliability

For typical continuous drive applications, I/O pins configured between 2 mA and 12 mA and operating at -40 to 85°C, meet the standard 10-year lifetime reliability. If a continuous current sink of 18 mA is required, then operation is limited to 0 to 75°C in order to meet the standard 10-year reliability.

At 105°C, I/O configured for continuous drive meet the standard 2.5 year lifetime reliability.

In typical switching applications (40% switch rate) operating at -40 to 85°C, all I/O configurations except 2 mA meet the standard 10-year lifetime reliability with 50-pF loading. By limiting the capacitive loading to 20 pF for an I/O configured to 2 mA, the 10-year lifetime reliability can be met at -40 to 85°C.

In typical switching applications (40% switch rate) operating at 105°C, all I/O configurations except 2 mA meet the standard 2.5-year lifetime reliability. By reducing the capacitive loading to 20 pF with a typical switching rate at 105°C, a 2-mA I/O configuration meets a 2.5 year lifetime reliability.

32.4 Load Conditions

Table 32-11 on page 2103 contains the load conditions used for timing measurements.

Figure 32-1. Load Conditions**Table 32-11. Load Conditions**

Signals	Load Value (C_L)
LCDDATA[23:0]	25 pF

Table 32-11. Load Conditions (continued)

Signals	Load Value (C_L)
EPIOS[35:0] SDRAM interface	30 pF
EPIOS[35:0] General-Purpose interface	
EPIOS[35:0] Host-Bus interface	
EPIOS[35:0] PSRAM interface	40 pF
All other digital I/O signals	50 pF

32.5 JTAG and Boundary Scan

Table 32-12. JTAG Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
J1	F_{TCK}	TCK operational clock frequency ^a	0	-	10	MHz

32.6 Power and Brown-Out

Table 32-13. Power and Brown-Out Levels^a

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
P1	T_{VDDA_RISE}	Analog Supply voltage (V_{DDA}) rise time	-	-	∞	μs
P2	T_{VDD_RISE}	I/O Supply voltage (V_{DD}) rise time	-	-	∞	μs
P3	$T_{VDDC_RISE}^b$	Core Supply Voltage (V_{DDC}) rise time	10	-	150	μs
P4	V_{POR}	Power-On Reset Threshold	2.00	2.30	2.55	V
P5	V_{DDA_POK}	V_{DDA} Power-OK Threshold (Rising Edge)	2.67	2.82	2.97	V
P6	V_{DDA_BOR0}	V_{DDA} Brown-Out Reset Threshold	2.71	2.80	2.89	V
P7	V_{DD_POK}	V_{DD} Power-OK Threshold (Rising Edge)	2.65	2.80	2.90	V
		V_{DD} Power-OK Threshold (Falling Edge)	2.67	2.76	2.85	V
P8	V_{DD_BOR0}	V_{DD} Brown-Out Reset Threshold	2.77	2.86	2.95	V
P9	V_{DDC_POK}	V_{DDC} Power-OK Threshold (Rising Edge)	0.85	0.95	1.10	V
		V_{DDC} Power-OK Threshold (Falling Edge)	0.71	0.80	0.85	V

a. All values in this table are based on simulation and are pending characterization.

b. The MIN and MAX values are based on an external filter capacitor load within the range of C_{LDO} . Please refer to "On-Chip Low Drop-Out (LDO) Regulator" on page 2112 for the C_{LDO} value.

32.6.1 V_{DDA} Levels

The V_{DDA} supply has three monitors:

- Power-On Reset (POR)
- Power-OK (POK)
- Brown Out Reset (BOR)

The POR monitor is used to keep the analog circuitry in reset until the V_{DDA} supply has reached the correct range for the analog circuitry to begin operating. The POK monitor is used to keep the digital circuitry in reset until the V_{DDA} power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. The BOR monitor is used to generate a reset to the device or assert an interrupt if the V_{DDA} supply drops below its operational range.

Note: V_{DDA} BOR and V_{DD} BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- BORRIS bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 272.
- BORMIS bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the BORIM bit in the **Interrupt Mask Control (IMC)** register has been set. See page 274 and page 276.
- BOR bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 278.

In addition, the following bits control both BOR events:

- BORIM bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- VDDA_UBOR0 and VDD_UBOR0 bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 230 for more information on how to configure these registers.

Figure 32-4 on page 2107 shows the relationship between V_{DDA}, POK, POR and a BOR event.

Figure 32-4. Power and Brown-Out Assertions vs V_{DDA} Levels

32.6.2 V_{DD} Levels

The V_{DD} supply has two monitors:

- Power-OK (POK)
- Brown Out Reset (BOR)

The POK monitor is used to keep the digital circuitry in reset until the V_{DD} power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. The BOR monitor is used to generate a reset to the device or assert an interrupt if the V_{DD} supply drops below its operational range.

Note: V_{DDA} BOR and V_{DD} BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- BORRIS bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 272.
- BORMIS bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the BORIM bit in the **Interrupt Mask Control (IMC)** register has been set. See page 274 and page 276.
- BOR bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 278.

In addition, the following bits control both BOR events:

- BORIM bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- VDDA_UBOR0 and VDD_UBOR0 bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 230 for more information on how to configure these registers.

Figure 32-5 on page 2108 shows the relationship between V_{DD} , POK, POR and a BOR event.

Figure 32-5. Power and Brown-Out Assertions vs V_{DD} Levels

32.6.3 V_{DDC} Levels

The V_{DDC} supply has one monitor, the Power-OK (POK). The POK monitor is used to keep the digital circuitry in reset until the V_{DDC} power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. Figure 32-6 on page 2109 shows the relationship between POK and V_{DDC} .

Figure 32-6. POK Assertion vs V_{DDC}

32.6.4 Response

32.6.4.1 V_{DD} Glitch Response

Figure 32-7 on page 2109 shows the response of the BOR and the POR circuit to glitches on the VDD supply.

Figure 32-7. POR-BOR V_{DD} Glitch Response

32.6.4.2 V_{DD} Droop Response

Figure 32-8 on page 2110 shows the response of the BOR and the POR monitors to a drop on the VDD supply.

Figure 32-8. POR-BOR V_{DD} Droop Response

32.7 Reset

Table 32-14. Reset Characteristics^a

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
R1	$T_{DPORDLY}^b$	Digital POR to Internal Reset assertion delay ^c	0.44	-	126	μs
R2	T_{IRTO}^b	Internal Reset timeout	-	7	-	ms
R3	$T_{BOR0DLY}^b$	BOR0 to Internal Reset assertion delay ^c	0.44	-	125	μs
R4	T_{RSTMIN}	Minimum \overline{RST} pulse width	-	$0.25^d/100^e$	-	μs
R5	$T_{IRHWDLY}$	\overline{RST} to Internal Reset assertion delay	-	0.85	-	μs
R6	T_{IRSWR}^b	Internal reset timeout after software-initiated system reset	-	2.44	-	μs
R7	T_{IRWDR}^b	Internal reset timeout after Watchdog reset	-	2.44	-	μs
R8	T_{IRMFR}^b	Internal reset timeout after MOSC failure reset	-	2.44	-	μs

a. Minimum timings are for reset assertion using PIOSC as a clock source. Maximum timings are for reset assertion using LFIOSC in Deep-Sleep Operation.

b. These values are based on simulation.

c. Timing values are dependent on the V_{DD} power-down ramp rate.

d. Standard operation.

e. Deep-sleep operation with PIOSC powered down.

Figure 32-9. Digital Power-On Reset Timing

The digital Power-On Reset is only released when the analog Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges.

Figure 32-10. Brown-Out Reset Timing**Figure 32-11. External Reset Timing (\overline{RST})**

Figure 32-12. Software Reset Timing**Figure 32-13. Watchdog Reset Timing****Figure 32-14. MOSC Failure Reset Timing**

32.8 On-Chip Low Drop-Out (LDO) Regulator

Table 32-15. LDO Regulator Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
C_{LDO}	External filter capacitor size for internal power supply ^a	2.5	-	4.0	μF
ESR	Filter capacitor equivalent series resistance	0	-	100	$\text{m}\Omega$
ESL	Filter capacitor equivalent series inductance	-	-	0.5	nH
V_{LDO}	LDO output voltage, Run mode	1.13	1.2	1.27	V

Table 32-15. LDO Regulator Characteristics (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
I _{INRUSH}	Inrush current	50	-	250	mA

a. The capacitor should be connected as close as possible to pin E10.

32.9 Clocks

The following sections provide specifications on the various clock sources and mode.

32.9.1 PLL Specifications

The following tables provide specifications for using the PLL.

Note: If the integrated Ethernet PHY is used in this device, then F_{REF_XTAL} and F_{REF_EXT} are required to be 25 MHz.

Table 32-16. Phase Locked Loop (PLL) Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
F _{REF_XTAL}	Crystal reference	5	-	25	MHz
F _{REF_EXT}	External clock reference	5	-	25	MHz
F _{PLL_R}	PLL VCO frequency at 1.2V ^a	-	-	480	MHz
F _{PLL_S}	PLL VCO frequency at 0.9V ^b	-	-	480	MHz
T _{READY}	PLL lock time (enabling the PLL) when PLL is transitioning from power down to power up	-	-	512 * (reference clock period)	μs
	PLL lock time when the PLL VCO frequency is changed (PLL is already enabled)	-	-	128 * (reference clock period)	μs
	PLL lock time, changing the OSCSRC between MOSC and PIOSC	-	-	128 * (reference clock period)	μs

a. PLL frequency is manually calculated using the values in the PLLFREQ0 and PLLFREQ1 registers.

b. If the LDO is dropped to 0.9V, the system must be run 1/4 of the maximum frequency at most. The Q value in the PLLFREQ1 register must be set to 0x3 rather than using the PSYSDIV field in the RSCLKCFG register for the divisor.

32.9.1.1 PLL Configuration

The PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the PLL to drive the output. The PLL is controlled using the **PLLREQ0**, **PLLREQ1** and **PLLSTAT** registers. Changes made to these registers do not become active until after the NEWFREQ bit in the **RSCLKCFG** register is enabled.

The clock source for the main PLL is selected by configuring the PLLSRC field in the **Run and Sleep Clock Configuration (RSCLKCFG)** register.

The PLL allows for the generation of system clock frequencies in excess of the reference clock provided. The reference clocks for the PLL are the PIOSC and the MOSC. The PLL is controlled by two registers, **PLLREQ0** and **PLLREQ1**. The PLL VCO frequency (f_{VCO}) is determined through the following calculation:

$$f_{VCO} = f_{IN} * MDIV$$

where

$$f_{IN} = f_{XTAL}/(Q+1)(N+1) \text{ or } f_{PIOSC}/(Q+1)(N+1)$$

$$MDIV = MINT + (MFRAC / 1024)$$

The Q and N values are programmed in the **PLLREQ1** register. Note that to reduce jitter, MFRAC should be programmed to 0x0.

When the PLL is active, the system clock frequency (SysClk) is calculated using the following equation:

$$SysClk = f_{VCO} / (PSYSDIV + 1)$$

The PLL system divisor factor (PSYSDIV) determines the value of the system clock. Table 5-6 on page 248 shows how the system divisor encodings affect the system clock frequency when the $f_{VCO} = 480$ MHz.

Table 32-17. System Divisor Factors for $f_{VCO}=480$ MHz

System Clock (SYSCLK) (MHz)	f_{VCO} (MHz)= 480 MHz
	System Divisors (PSYSDIV +1) ^a
120	4
60	8
48	10
30	16
24	20
12	40
6	80

a. The use of non-integer divisors introduce additional jitter which may affect interface performance.

If the main oscillator provides the clock reference to the PLL, the translation provided by hardware and used to program the PLL is available for software in the **PLL Frequency n (PLLREQn)** registers (see page 303). The internal translation provides a translation within $\pm 1\%$ of the targeted PLL VCO frequency. Table 5-7 on page 249 shows the actual PLL frequency and error for a given crystal choice.

Table 5-7 on page 249 provides examples of the programming expected for the **PLLREQ0** and **PLLREQ1** registers. The first column specifies the input crystal frequency and the last column displays the PLL frequency given the values of MINT and N, when Q=0.

Table 32-18. Actual PLL Frequency^a

Crystal Frequency (MHz)	MINT (Decimal Value)	MINT (Hexadecimal Value)	N	Reference Frequency (MHz) ^b	PLL Frequency (MHz)
5	64	0x40	0x0	5	320
6	160	0x35	0x2	2	320
8	40	0x28	0x0	8	320
10	32	0x20	0x0	10	320
12	80	0x50	0x2	4	320
16	20	0x14	0x0	16	320
18	160	0xA0	0x8	2	320
20	16	0x10	0x0	20	320
24	40	0x28	0x2	8	320

Table 32-18. Actual PLL Frequency (continued)

Crystal Frequency (MHz)	MINT (Decimal Value)	MINT (Hexadecimal Value)	N	Reference Frequency (MHz) ^b	PLL Frequency (MHz)
25	64	0x40	0x4	5	320
5	96	0x60	0x0	5	480
6	80	0x50	0x0	6	480
8	60	0x3C	0x0	8	480
10	48	0x30	0x0	10	480
12	40	0x28	0x0	12	480
16	30	0x1E	0x0	16	480
18	80	0x50	0x2	6	480
20	24	0x18	0x0	20	480
24	20	0x14	0x0	24	480
25	96	0x60	0x4	5	480

a. For all examples listed, Q=0

b. For a given crystal frequency, N should be chosen such that the reference frequency is within 4 to 30 MHz.

32.9.2 PIOSC Specifications

Table 32-19. PIOSC Clock Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
F _{PIOSC}	Internal 16-MHz precision oscillator frequency variance (factory calibrated at 25 °C and 3.3 V) across the specified voltage and temperature range ^a	-	-	±3% ^b	-
T _{START}	PIOSC startup time ^c	-	-	1	μs

a. This parameter value remains valid if recalibration occurs.

b. ±3% can only be met with VDD±5%.

c. PIOSC startup time is part of reset and is included in the internal reset timeout value (T_{IRTOUT}) given in Table 32-14 on page 2110. Note that the T_{START} value is based on simulation.

32.9.3 Low-Frequency Internal Oscillator Specifications

Table 32-20. Low-Frequency Oscillator Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
F _{LFIOSC}	Internal low-frequency oscillator frequency	10 ^a	33	90 ^a	KHz

a. Preliminary, pending characterization.

32.9.4 Hibernation Clock Source Specifications

Table 32-21. Hibernation Internal Low Frequency Oscillator Clock Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
F _{HIBLFIOSC}	Internal Low Frequency Hibernation oscillator frequency	10	33	90	KHz

Table 32-22. Hibernation External Oscillator (XOSC) Input Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
$F_{HIBXOSC}^a$	Parallel resonance frequency	-	32.768	-	KHz
C_1, C_2	External load capacitance on XOSC0, XOSC1 pins ^b	12	-	24	pF
C_{PKG}	Device package stray shunt capacitance ^b	-	0.5	-	pF
C_{PCB}	PCB stray shunt capacitance ^b	-	0.5	-	pF
C_0	Crystal shunt capacitance ^b	-	3	-	pF
C_{SHUNT}	Total shunt capacitance ^b	-	-	4	pF
ESR	Crystal effective series resistance, OSCDRV = 0 ^c	-	-	50	kΩ
	Crystal effective series resistance, OSCDRV = 1 ^c	-	-	75	kΩ
DL	Oscillator output drive level	-	-	0.25	μW
T_{START}	Oscillator startup time, when using a crystal ^d	-	600	1500 ^e	ms
V_{IH}^f	CMOS input high level, when using an external oscillator with Supply > 3.3 V	2.64	-	-	V
	CMOS input high level, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.3 V	0.8 * Supply	-	-	V
V_{IL}^f	CMOS input low level, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.63 V	-	-	0.2 * Supply	V
V_{HYS}^f	CMOS input buffer hysteresis, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.63 V	360	960	1390	mV
DC _{HIBOSC_EXT}	External single-Ended (Bypass) reference duty cycle	30	-	70	%

a. The HIB XOSC pins are non-failsafe and must follow the limits detailed in “Non-Power I/O Pins” on page 2126.

b. See information below table.

c. Crystal ESR specified by crystal manufacturer.

d. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

e. Only valid for recommended supply conditions. Measured with OSCDRV bit set (high drive strength enabled, 24 pF).

f. Specification is relative to the larger of V_{DD} or V_{BAT} .

The load capacitors added on the board, C_1 and C_2 , should be chosen such that the following equation is satisfied (see Table 32-22 on page 2116 for typical values).

- C_L = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{PKG} + C_{PCB}$
- $C_{SHUNT} = C_{PKG} + C_{PCB} + C_0$ (total shunt capacitance seen across XOSC0, XOSC1)
- C_{PKG}, C_{PCB} as measured across the XOSC0, XOSC1 pins excluding the crystal
- Clear the OSCDRV bit in the **Hibernation Control (HIBCTL)** register for $C_{1,2} \leq 18$ pF; set the OSCDRV bit for $C_{1,2} > 18$ pF.
- C_0 = Shunt capacitance of crystal specified by the crystal manufacturer

32.9.5 Main Oscillator Specifications

Table 32-23. Main Oscillator Input Characteristics^a

Parameter	Parameter Name	Min	Nom	Max	Unit
F_{MOSC}	Parallel resonance frequency	4 ^b	-	25	MHz
$F_{REF_XTAL_BYPASS}$	External clock reference (PLL in BYPASS mode) ^c	0	-	120	MHz
C_1, C_2	External load capacitance on OSC0, OSC1 pins ^d	12	-	24	pF
C_{PKG}	Device package stray shunt capacitance ^d	-	0.5	-	pF
C_{PCB}	PCB stray shunt capacitance ^d	-	0.5	-	pF
C_{SHUNT}	Total shunt capacitance ^d	-	-	4	pF
ESR	Crystal effective series resistance, 4 MHz ^e	-	-	300	Ω
	Crystal effective series resistance, 6 MHz ^e	-	-	200	Ω
	Crystal effective series resistance, 8 MHz ^e	-	-	130	Ω
	Crystal effective series resistance, 12 MHz ^e	-	-	120	Ω
	Crystal effective series resistance, 16 MHz ^e	-	-	100	Ω
	Crystal effective series resistance, 25 MHz ^e	-	-	50	Ω
DL	Oscillator output drive level ^f	-	OSC_{PWR}	-	mW
T_{START}	Oscillator startup time, when using a crystal ^g	-	-	18	ms
V_{IH}	CMOS input high level, when using an external oscillator	$0.65 * V_{DD}$	-	V_{DD}	V
V_{IL}	CMOS input low level, when using an external oscillator	GND	-	$0.35 * V_{DD}$	V
V_{HYS}	CMOS input buffer hysteresis, when using an external oscillator	150	-	-	mV
DC_{OSC_EXT}	External clock reference duty cycle	45	-	55	%

a. Refer to Table 32-50 on page 2144 and Table 32-51 on page 2145 for additional Ethernet crystal requirements.

b. 5 MHz is the minimum when using the PLL.

c. Pending characterization

d. See information below table.

e. Crystal ESR specified by crystal manufacturer.

f. $OSC_{PWR} = (2 * \pi * F_p * C_L * 2.5)^2 * ESR / 2$. An estimation of the typical power delivered to the crystal is based on the C_L , F_p and ESR parameters of the crystal in the circuit as calculated by the OSC_{PWR} equation. Ensure that the value calculated for OSC_{PWR} does not exceed the crystal's drive-level maximum.

g. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

The load capacitors added on the board, C_1 and C_2 , should be chosen such that the following equation is satisfied (see Table 32-23 on page 2117 for typical values and Table 32-24 on page 2118 for detailed crystal parameter information).

- C_L = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{SHUNT}$
- $C_{SHUNT} = C_0 + C_{PKG} + C_{PCB}$ (total shunt capacitance seen across OSC0, OSC1 crystal inputs)
- C_{PKG}, C_{PCB} = the mutual caps as measured across the OSC0, OSC1 pins excluding the crystal.
- C_0 = Shunt capacitance of crystal specified by the crystal manufacturer

Table 32-24 on page 2118 lists part numbers of crystals that have been simulated and confirmed to operate within the specifications in Table 32-23 on page 2117. Other crystals that have nearly identical crystal parameters can be expected to work as well.

In the table below, the crystal parameters labeled C₀, C₁ and L₁ are values that are obtained from the crystal manufacturer. These numbers are usually a result of testing a relevant batch of crystals on a network analyzer. The parameters labeled ESR, DL and C_L are maximum numbers usually available in the data sheet for a crystal.

The table also includes three columns of Recommended Component Values. These values apply to system board components. C₁ and C₂ are the values in pico Farads of the load capacitors that should be put on each leg of the crystal pins to ensure oscillation at the correct frequency. R_s is the value in kΩ of a resistor that is placed in series with the crystal between the OSC1 pin and the crystal pin. R_s dissipates some of the power so the Max DI crystal parameter is not exceeded. Only use the recommended C₁, C₂, and R_s values with the associated crystal part. The values in the table were used in the simulation to ensure crystal startup and to determine the worst case drive level (WC DI). The value in the WC DI column should not be greater than the Max DI Crystal parameter. The WC DI value can be used to determine if a crystal with similar parameter values but a lower Max DI value is acceptable.

Table 32-24. Crystal Parameters

a. R_S values as low as 0 Ohms can be used. Using a lower R_S value will result in the WC DL to increase towards the Max DL of the crystal.

b. Although this ESR value is outside of the recommended crystal ESR maximum for this frequency, this crystal has been simulated to confirm proper operation and is valid for use with this device.

c. R_S values as low as 500 Ohms can be used. Using a lower R_S value will result in the WC DL to increase towards the Max DL of the crystal.

32.9.6 System Clock Specification with ADC Operation

Table 32-25. System Clock Characteristics with ADC Operation

Parameter	Parameter Name	Min	Nom	Max	Unit
F_{sysadc}	System clock frequency when the ADC module is operating (when PLL is bypassed).	-	16	-	MHz

32.9.7 System Clock Specification with USB Operation

Table 32-26. System Clock Characteristics with USB Operation

Parameter	Parameter Name	Min	Nom	Max	Unit
F_{sysusb}	System clock frequency when the USB module is operating (note that MOSC must be the clock source, either with or without using the PLL)	30	-	-	MHz

32.10 Sleep Modes

The following tables can be used to calculate the maximum wake time from Sleep or Deep Sleep depending on the specific application. Depending on the application configuration, each of the parameters, except for T_{FLASH} , add sequential latency to the wake time. Flash restoration happens in parallel to the other wake processes and its wake time is normally absorbed by the other latencies. As an example, the wake time for a device in Deep Sleep, with the PIOSC and PLL turned off and the Flash and SRAM in low power mode is calculated as follows:

$$\text{Wake Time} = T_{PIOSCDS} + T_{PLLDS} + T_{SRAMLPDS}$$

T_{FLASH} does not contribute to this equation since all other parameters are greater in value.

Note that in Sleep mode the wake time due to a clock source is zero because the device uses the same clock configuration in Run mode; thus, there is no latency involved with respect to the clocks.

Table 32-27. Wake from Sleep Characteristics

Parameter No	Parameter	Parameter Name	Min	Nom	Max	Unit
D1	T_{PIOSC}	Time to restore PIOSC as System Clock in Sleep mode	-	-	N/A ^a	μs
D2	T_{MOSC}	Time to restore MOSC as System Clock in Sleep mode	-	-	N/A ^b	μs
D3	T_{PLL}	Time to restore PLL as System Clock in Sleep mode	-	-	N/A ^c	μs
D4	T_{LDO}	Time to restore LDO to 1.2 V in Sleep mode	-	-	39	μs
D5	T_{FLASH}	Time to restore Flash to active state from low power state in Sleep mode	-	-	5	μs
D6	T_{SRAMLP}	Time to restore SRAM to active state from low power state in Sleep mode	-	-	15	μs
D7	$T_{SRAMSTBY}$	Time to restore SRAM to active state from standby state in Sleep mode	-	-	15	μs

a. Because the PIOSC is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

b. Because the MOSC is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

c. Because the PLL is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

Table 32-28. Wake from Deep Sleep Characteristics

Parameter No	Parameter	Parameter Name	Min	Nom	Max	Unit
D8	$T_{PIOSCDS}$	Time to restore PIOSC as System Clock in Deep Sleep Mode	-	-	14	Deep Sleep Clock Cycles ^a
D9	T_{MOSCDS}	Time to restore MOSC as System Clock in Deep Sleep Mode	-	-	18	ms
D10	T_{PLLDS}	Time to restore PLL as System Clock in Deep Sleep Mode	-	-	1 cycle of Deep Sleep Clock + 512 cycles of PLL reference Clock ^a	clocks
D11	T_{LDODS}	Time to restore LDO to 1.2 V in Deep Sleep Mode	-	-	39	μ s
D12	$T_{FLASHLPDS}$	Time to restore Flash to active state from low power state	-	-	5	μ s
D13	$T_{SRAMLPDS}$	Time to restore SRAM to active state from low power state	-	-	15	μ s
D14	$T_{SRAMSTBYDS}$	Time to restore SRAM to active state from standby state	-	-	15	μ s

a. Deep Sleep Clock can vary. See page 292 for the Deep Sleep Clock options.

32.11 Hibernation Module

The Hibernation module requires special system implementation considerations because it is intended to power down all other sections of its host device, refer to “Hibernation Module” on page 561.

Table 32-29. Hibernation Module Battery Characteristics

Parameter	Parameter Name	Min	Nominal	Max	Unit
V_{BAT}	Battery supply voltage	1.8	3.0	3.6 ^a	V
V_{BATRMP} ^b	V_{BAT} battery supply voltage ramp time	0	-	0.7	V/ μ s
V_{LOWBAT}	Low battery detect voltage, $V_{BATSEL}=0x0$	1.8	1.9	2.0	V
	Low battery detect voltage, $V_{BATSEL}=0x1$	2.0	2.1	2.2	V
	Low battery detect voltage, $V_{BATSEL}=0x2$	2.2	2.3	2.4	V
	Low battery detect voltage, $V_{BATSEL}=0x3$	2.4	2.5	2.6	V

a. To ensure proper functionality, any voltage input higher than V_{BAT} Max, must be connected through a diode.

b. For recommended V_{BAT} RC circuit values, refer to the diagrams located in “Hibernation Clock Source” on page 565.

Table 32-30. Hibernation Module Characteristics

Parameter No	Parameter	Parameter Name	Min	Nom	Max	Unit
H1	T_{WAKE}	\overline{WAKE} assertion time	100	-	-	ns
H2	$T_{WAKE_TO_HIB}$	\overline{WAKE} assert to \overline{HIB} desassert (wake up time)	-	-	1	Hibernation clock period
H3	T_{VDD_RAMP}	V_{DD} ramp to 3.0 V	-	Depends on characteristics of power supply	-	μ s
H4	T_{VDD_CODE}	V_{DD} at 3.0 V to internal POR deassert; first instruction executes	-	-	500	μ s

Table 32-30. Hibernation Module Characteristics (continued)

Parameter No	Parameter	Parameter Name	Min	Nom	Max	Unit
H5	$D_{C_{RTCCLK}}$	Duty cycle for RTCCLK output signal, when using a 32.768-kHz crystal	40	-	60	%
		Duty cycle for RTCCLK output signal, when using a 32.768-kHz external single-ended (bypass) clock source	30	-	70	%

Table 32-31. Hibernation Module Tamper I/O Characteristics

Parameter	Parameter Name	Min	Nominal	Max	Unit
R_{TPU}	TMPRn pull-up resistor	-	4.4	-	$M\Omega$
T_{SP}	TMPRn pulse width with short glitch filter	62	-	-	μs
T_{LP}	TMPRn pulse width with long glitch filter	94	-	-	ms
T_{NMIS}	TMPRn assertion to NMI (short glitch filter)	-	-	95	μs
T_{NMIIL}	TMPRn assertion to NMI (long glitch filter)	-	-	94	ms
V_{IH}	TMPRn high-level input voltage when operating from VBAT	$V_{BAT} * 0.8$	-	-	V

Figure 32-15. Hibernation Module Timing

32.12 Flash Memory

Table 32-32. Flash Memory Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
PE_{CYC}	Number of program/erase cycles ^a	100,000	-	-	cycles
T_{RET}	Data retention with 100% power-on hours at $T_J=85^\circ C$	20	-	-	years
$T_{RET_EXTTEMP}$	Data retention with 10% power-on hours at $T_J=125^\circ C$ and 90% power-on hours at $T_J=100^\circ C$	11	-	-	years
T_{PROG64}	Program time for double-word-aligned (64 bits) data ^b	30	50	300	μs
T_{ERASE}	Page erase time, <1k cycles	-	8	15	ms
	Page erase time, 10k cycles	-	15	40	ms
	Page erase time, 100k cycles	-	75	500	ms

Table 32-32. Flash Memory Characteristics (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
T_{ME}	Mass erase time, <1k cycles	-	10	25	ms
	Mass erase time, 10k cycles	-	20	70	ms
	Mass erase time, 100k cycles	-	300	2500	ms

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

b. If programming fewer than 64 bits of data, the programming time is the same. For example, if only 32 bits of data need to be programmed, the other 32 bits are masked off.

32.13 EEPROM

Table 32-33. EEPROM Characteristics^a

Parameter	Parameter Name	Min	Nom	Max	Unit
EPE_{CYC}^b	Number of mass program/erase cycles of a single word ^c	500,000	-	-	cycles
ET_{RET}	Data retention with 100% power-on hours at $T_J=85^\circ\text{C}$	20	-	-	years
$ET_{RET_EXTTEMP}$	Data retention with 10% power-on hours at $T_J=125^\circ\text{C}$ and 90% power-on hours at $T_J=100^\circ\text{C}$	11	-	-	years
ET_{PROG}	Program time for 32 bits of data with memory space available	-	110	600	μs
	Program time for 32 bits of data in which a copy to the copy buffer is required, the copy buffer has space and less than 10% of EEPROM endurance used	-	30	-	ms
	Program time for 32 bits of data in which a copy to the copy buffer is required, the copy buffer has space and greater than 90% of EEPROM endurance used	-	-	900	ms
	Program time for 32 bits of data in which a copy of the copy buffer is required, the copy buffer requires an erase and less than 10% of EEPROM endurance used	-	60	-	ms
	Program time for 32 bits of data a copy to the copy buffer is required, the copy buffer requires an erase and greater than 90% of EEPROM endurance used	-	-	1800	ms
ET_{READ}	Read access time	-	-	-	system clocks
ET_{ME}	Mass erase time, <1k cycles	-	8	15	ms
	Mass erase time, 10k cycles	-	15	40	ms
	Mass erase time, 100k cycles	-	75	500	ms
ET_{PORDLY}	EEPROM recovery Power-On Reset delay ^d	-	-	2000 ^e	ms

a. Because the EEPROM operates as a background task and does not prevent the CPU from executing from Flash memory, the operation will complete within the maximum time specified provided the EEPROM operation is not stalled by a Flash memory program or erase operation.

b. One word can be written more than 500K times, but these writes impact the endurance of the words in the meta-block that the word is within. Different words can be written such that any or all words can be written more than 500K times when write counts per word stay about the same. See the section called “Endurance” on page 649 for more information.

c. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

d. This parameter applies only in situations where a power-down or brown-out event occurs during an EEPROM program or erase operation. For all other sequences, there is no impact to normal Power-On Reset (POR) timing. This delay is in addition to other POR delays.

e. The maximum Power-On Reset delay increases as the EEPROM memory ages towards its endurance limit.

32.14 Input/Output Pin Characteristics

Note: All GPIO signals are 3.3-V tolerant, except for PB1 (USB0VBUS) which is 5-V tolerant. See “Signal Description” on page 770 for more information on GPIO configuration.

Two types of pads are provided on the device:

- Fast GPIO pads: These pads provide variable, programmable drive strength and optimized voltage output levels.
- Slow GPIO pads: These pads provide 2-mA drive strength and are designed to be sensitive to voltage inputs. The following GPIOs port pins are designed with Slow GPIO Pads:
 - PJ1

Note: Port pins PL6 and PL7 operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**.

Note: Port pins PM[7:4] operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins.

Table 32-34. Fast GPIO Module Characteristics ^{abcd}

Parameter	Parameter Name	Min	Nom	Max	Unit
C_{LGPIO}	Capacitive loading for measurements given in this table ^e	-	-	50	pF
R_{GPIOPU}	Fast GPIO internal pull-up resistor ^f	12.1	16.0	20.2	kΩ
$R_{GPIOPU4MA}$	Fast GPIO PL6 and PL7 (4-mA only) pull-up resistor	25	-	40	kΩ
R_{GPIOPD}	Fast GPIO internal pull-down resistor ^f	13.0	20.5	35.5	kΩ
$R_{GPIOPD4MA}$	Fast GPIO PL6 and PL7 (4-mA only) pull-down resistor	10	14.3	17	kΩ
I_{LKG+}	Fast GPIO input leakage current, $0 \text{ V} \leq V_{IN} \leq V_{DD}$ GPIO pins ^g	-	-	400	nA
	Fast GPIO input leakage current, $0 \text{ V} < V_{IN} \leq V_{DD}$, Fast GPIO pins configured as ADC or analog comparator inputs	-	-	400	nA
I_{INJ-}	DC injection current, $V_{IN} \leq 0 \text{ V}$	-	-	60	μA
$I_{MAXINJ-}$	Max negative injection if not voltage protected ^d	-	-	-0.5	mA
T_{GPIOR}	Fast GPIO rise time, 2-mA drive ^h	-	7.85	11.73	ns
	Fast GPIO rise time, 4-mA drive ^h		4.15	6.35	ns
	Fast GPIO rise time, 8-mA drive ^h		2.33	3.73	ns
	Fast GPIO rise time, 8-mA drive with slew rate control ^h		3.77	5.76	ns
	Fast GPIO rise time, 10-mA drive ^h		1.98	3.22	ns
	Fast GPIO rise time, 12-mA drive ^h		1.75	2.9	ns

Table 32-34. Fast GPIO Module Characteristics (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
T_{GPIOF}	Fast GPIO fall time, 2-mA drive ⁱ	-	10.3	16.5	ns
	Fast GPIO fall time, 4-mA drive ⁱ		5.15	8.29	ns
	Fast GPIO fall time, 8-mA drive ⁱ		2.58	4.16	ns
	Fast GPIO fall time, 8-mA drive with slew rate control ⁱ		3.54	5.55	ns
	Fast GPIO fall time, 10-mA drive ⁱ		2.07	3.34	ns
	Fast GPIO fall time, 12-mA drive ⁱ		1.73	2.78	ns

- a. V_{DD} must be within the range specified in Table 32-6 on page 2101.
- b. Leakage and Injection current characteristics specified in this table also apply to XOSC0 and XOSC1 inputs.
- c. Note that for the ADC's external reference inputs, care must be taken to avoid a current limiting resistor (refer to I_{VREF} spec in Table 32-44 on page 2134)
- d. I/O pads should be protected if at any point the IO voltage has a possibility of going outside the limits shown in the table.
If the part is unpowered, the IO pad Voltage or Current must be limited (as shown in this table) to avoid powering the part through the IO pad, causing potential irreversible damage.
- e. Refer to individual peripheral sections for specific loading information.
- f. This value includes all GPIO except for port pins PL6 and PL7.
- g. The leakage current is measured with V_{IN} applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pull-up/pull-down resistor is disabled.
- h. Time measured from 20% to 80% of V_{DD} .
- i. Time measured from 80% to 20% of V_{DD} .

Table 32-35. Slow GPIO Module Characteristics^{abc}

Parameter	Parameter Name	Min	Nom	Max	Unit
C_{LGPIO}	Capacitive loading for measurements given in this table ^d	-	-	50	pF
R_{GPIOPU}	Slow GPIO internal pull-up resistor	13.8	20.0	31.4	kΩ
R_{GPIOPD}	Slow GPIO internal pull-down resistor	13.0	20.5	35.5	kΩ
I_{LKG+}	Slow GPIO input leakage current, 0 V ≤ $V_{IN} \leq V_{DD}$, GPIO pins ^e	-	-	3.25	nA
	Slow GPIO input leakage current, 0 V < $V_{IN} \leq V_{DD}$, GPIO pins configured as ADC or analog comparator inputs	-	-	3.25	nA
I_{INJ-}	DC injection current, $V_{IN} \leq 0$ V	-	-	3.42	μA
T_{GPIOR}	Slow GPIO rise time, 2-mA drive ^f	-	19.3	29.8	ns
T_{GPIOF}	Slow GPIO fall time, 2-mA drive ^g	-	12.8	21.1	ns

- a. V_{DD} must be within the range specified in Table 32-6 on page 2101.
- b. V_{IN} must be within the range specified in Table 32-1 on page 2099. Leakage current outside of this maximum voltage is not guaranteed and can result in permanent damage of the device.
- c. To avoid potential damage to the part, either the voltage or current on the non-Power, non-WAKE input/outputs should be limited externally as shown in this table.
- d. Refer to individual peripheral sections for specific loading information.
- e. The leakage current is measured with V_{IN} applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pull-up/pull-down resistor is disabled.
- f. Time measured from 20% to 80% of V_{DD} .
- g. Time measured from 80% to 20% of V_{DD} .

32.14.1 Types of I/O Pins and ESD Protection

Caution – All device I/Os pins, except for PB1, are NOT 5V tolerant; voltages in excess of the limits shown in Table 32-6 on page 2101 can permanently damage the device. PB1 is used for the USB's USB0VBUS signal, which requires a 5-V input.

32.14.1.1 Hibernate $\overline{\text{WAKE}}$ pin

The Hibernate $\overline{\text{WAKE}}$ pin uses ESD protection, similar to the one shown in Figure 32-16 on page 2126. This ESD protection prevents a direct path between this pad and any power supply rails in the device. The $\overline{\text{WAKE}}$ pad input voltage should be kept inside the maximum ratings specified in Table 32-1 on page 2099 to ensure current leakage and current injections are within acceptable range. Current leakages and current injection for these pins are specified in Table 32-36 on page 2126.

Figure 32-16. ESD Protection

Table 32-36. Pad Voltage/Current Characteristics for Hibernate $\overline{\text{WAKE}}$ Pin^{ab}

Parameter	Parameter Name	Min	Nom	Max	Unit
I_{LKG+}	Positive IO leakage for $V_{DD} \leq V_{IN} \leq V_{BAT} + 0.3V$	-	-	300	nA
I_{LKG-}	Negative IO leakage for $-0.3V \leq V_{IN} \leq 0V^c$	-	-	43.3	μA
I_{INJ+}	Max positive injection if not voltage protected ^d	-	-	2	mA
I_{INJ-}	Max negative injection if not voltage protected ^d	-	-	-0.5	mA

a. V_{IN} must be within the range specified in Table 32-1 on page 2099. Leakage current outside of this maximum voltage is not guaranteed and can result in permanent damage of the device.

b. V_{DD} must be within the range specified in Table 32-6 on page 2101.

c. Leakage outside the minimum range (-0.3V) is unbounded and must be limited to I_{INJ-} using an external resistor.

d. If the I/O pad is not voltage limited, it should be current limited (to I_{INJ+} and I_{INJ-}) if there is any possibility of the pad voltage exceeding the V_{IO} limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

32.14.1.2 Non-Power I/O Pins

Most non-power I/Os (with the exception of the I/O pad for Hibernate $\overline{\text{WAKE}}$ input) have ESD protection as shown in Figure 32-17 on page 2127.

These I/Os have an ESD clamp to ground and a diode connection to the corresponding power supply rail. The voltage and current of these I/Os should follow the specifications in Table 32-37 on page 2127 to prevent potential damage to the device. In addition, it is recommended that the ADC external reference specifications in Table 32-44 on page 2134 be adhered to prevent any gain error.

Figure 32-17. ESD Protection for Non-Power Pins (Except WAKE Signal)**Table 32-37. Non-Power I/O Pad Voltage/Current Characteristics**^{abc}

Parameter	Parameter Name	Min	Nom	Max	Unit
V _{IO} ^d	IO pad voltage limits if voltage protected	-0.3	V _{DD}	V _{DD} +0.3	V
I _{LKG+}	Positive IO leakage for V _{DD} ≤ V _{IN} ≤ V _{IO} MAX ^e	-	-	400	nA
I _{LKG-}	Negative IO leakage for V _{IO} MIN ≤ V _{IN} ≤ 0V ^e	-	-	60	µA
I _{INJ+}	Max positive injection if not voltage protected ^f	-	-	2	mA
I _{INJ-}	Max negative injection if not voltage protected ^f	-	-	-0.5	mA

- a. To avoid potential damage to the part, either the voltage or current on the non-Power, non-WAKE input/outputs should be limited externally as shown in this table.
- b. Note that for the ADC's external reference inputs, care must be taken to avoid a current limiting resistor (refer to IVREF spec in Table 32-44 on page 2134)
- c. I/O pads should be protected if at any point the IO voltage has a possibility of going outside the limits shown in the table. If the part is unpowered, the IO pad Voltage or Current must be limited (as shown in this table) to avoid powering the part through the IO pad, causing potential irreversible damage.
- d. The Hibernate XOSC pins are non-failsafe and should follow the limits for V_{IO} with respect to both V_{DD} and V_{BAT}. Thus V_{IO} for the HIB XOSC pins should also fall within a MIN of -0.3 and a MAX of V_{BAT} + 0.3.
- e. MIN and MAX leakage current for the case when the I/O is voltage protected to V_{IO} Min or V_{IO} Max.
- f. If the I/O pad is not voltage limited, it should be current limited (to I_{INJ+} and I_{INJ-}) if there is any possibility of the pad voltage exceeding the V_{IO} limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

32.15 External Peripheral Interface (EPI)

Table 32-38. EPI Interface Load Conditions

Signals	Load Value (C _L)
EPI0S[35:0] SDRAM interface	
EPI0S[35:0] General-Purpose interface	30 pF
EPI0S[35:0] Host-Bus interface	
EPI0S[35:0] PSRAM interface	40 pF

When the EPI module is in SDRAM mode, EPI CLK must be configured to 12 mA. The EPI data bus can be configured to 8 mA. Table 32-39 on page 2128 shows the rise and fall times in SDRAM mode. When the EPI module is in Host-Bus or General-Purpose mode, the values in "Input/Output Pin Characteristics" on page 2124 should be used.

Table 32-39. EPI SDRAM Characteristics

Parameter	Parameter Name	Condition	Min	Nom	Max	Unit
T_{SDRAMR}	EPI Rise Time (from 20% to 80% of V_{DD})	12-mA drive, $C_L = 30 \text{ pF}$	-	2	3	ns
T_{SDRAMF}	EPI Fall Time (from 80% to 20% of V_{DD})	12-mA drive, $C_L = 30 \text{ pF}$	-	2	3	ns

Table 32-40. EPI SDRAM Interface Characteristics^a

Parameter No	Parameter	Parameter Name	Min	Nom	Max	Unit
E1	T_{CK}	SDRAM Clock period	16.67	-	-	ns
E2	T_{CH}	SDRAM Clock high time	8.33	-	-	ns
E3	T_{CL}	SDRAM Clock low time	8.33	-	-	ns
E4	T_{COV}	CLK to output valid	-	-	4	ns
E5	T_{COI}	CLK to output invalid	-	-	4	ns
E6	T_{COT}	CLK to output tristate	-	-	4	ns
E7	T_S	Input set up to CLK	8.5	-	-	ns
E8	T_H	CLK to input hold	0	-	-	ns
E9	T_{PU}	Power-up time	100	-	-	μs
E10	T_{RP}	Precharge all banks	20	-	-	ns
E11	T_{RFC}	Auto refresh	66	-	-	ns
E12	T_{MRD}	Program mode register	2	-	-	EPI CLK

a. The EPI SDRAM interface must use 12-mA drive.

Figure 32-18. SDRAM Initialization and Load Mode Register Timing

Notes:

1. If CS is high at clock high time, all applied commands are NOP.
2. The Mode register may be loaded prior to the auto refresh cycles if desired.
3. JEDEC and PC100 specify three clocks.
4. Outputs are guaranteed High-Z after command is issued.

Figure 32-27. PSRAM Single Burst Write

32.16 Analog-to-Digital Converter (ADC)

Table 32-44. ADC Electrical Characteristics for ADC at 1 Msps^{ab}

Parameter	Parameter Name	Min	Nom	Max	Unit
POWER SUPPLY REQUIREMENTS					
V _{DDA}	ADC supply voltage	2.97	3.3	3.63	V
GNDA	ADC ground voltage	-	0	-	V
VDDA / GNDA VOLTAGE REFERENCE					
C _{REF}	Voltage reference decoupling capacitance	-	1.0 // 0.01 ^c	-	μF
EXTERNAL VOLTAGE REFERENCE INPUT					
V _{REFA+}	Positive external voltage reference for ADC, when VREF field in the ADCCTL register is 0x1 ^d	2.4	V _{DDA}	V _{DDA}	V
V _{REFA-}	Negative external voltage reference for ADC, when VREF field in the ADCCTL register is 0x1 ^d	GNDA	GNDA	0.3	V
I _{VREF}	Current on VREF+ input, using external V _{REF+} = 3.3 V	-	330.5	440	μA
I _{LVREF}	DC leakage current on VREF+ input when external VREF disabled	-	-	2.0	μA
C _{REF}	External reference decoupling capacitance ^d	-	1.0 // 0.01 ^c	-	μF
ANALOG INPUT					

Table 32-44. ADC Electrical Characteristics for ADC at 1 Msps (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
V_{ADCIN}	Single-ended, full-scale analog input voltage, internal reference ^{ef}	0	-	V_{DDA}	V
	Differential, full-scale analog input voltage, internal reference ^{eg}	$-V_{DDA}$	-	V_{VDDA}	V
	Single-ended, full-scale analog input voltage, external reference ^{df}	V_{REFA-}	-	V_{REFA+}	V
	Differential, full-scale analog input voltage, external reference ^{dh}	$-(V_{REFA+} - V_{REFA-})$	-	$V_{REFA+} - V_{REFA-}$	V
$V_{IN_{CM}}$	Input common mode voltage, differential mode ⁱ	-	-	$(V_{REFP} + V_{REFN}) / 2 \pm 25$	mV
I_L	ADC input leakage current ^j	-	-	2.0	μA
R_{ADC}	ADC equivalent input resistance ^j	-	-	2.5	k Ω
C_{ADC}	ADC equivalent input capacitance ^j	-	-	10	pF
R_S	Analog source resistance ^j	-	-	500	Ω
SAMPLING DYNAMICS					
F_{ADC}	ADC conversion clock frequency ^k	-	16	-	MHz
F_{CONV}	ADC conversion rate		1		MSPS
T_S	ADC sample time	-	250	-	ns
T_C	ADC conversion time ^l	-	1	-	μs
T_{LT}	Latency from trigger to start of conversion	-	2	-	ADC clocks
SYSTEM PERFORMANCE when using external reference ^{mn}					
N	Resolution		12		bits
INL	Integral nonlinearity error, over full input range	-	± 1.5	± 3.0	LSB
DNL	Differential nonlinearity error, over full input range	-	± 0.8	$+2.0/-1.0^o$	LSB
E_O	Offset error	-	± 1.0	± 3.0	LSB
E_G	Gain error ^p	-	± 2.0	± 3.0	LSB
E_T	Total unadjusted error, over full input range ^q	-	± 2.5	± 4.0	LSB
SYSTEM PERFORMANCE when using internal reference					
N	Resolution		12		bits
INL	Integral nonlinearity error, over full input range	-	± 1.5	± 3.0	LSB
DNL	Differential nonlinearity error, over full input range	-	± 0.8	$+2.0/-1.0^o$	LSB
E_O	Offset error	-	± 5.0	± 15.0	LSB
E_G	Gain error ^p	-	± 10.0	± 30.0	LSB
E_T	Total unadjusted error, over full input range ^q	-	± 10.0	± 30.0	LSB
DYNAMIC CHARACTERISTICS ^{rs}					
SNR_D	Signal-to-noise-ratio, Differential input, V_{ADCIN} : -20dB FS, 1KHz ^t	70	72	-	dB
SDR_D	Signal-to-distortion ratio, Differential input, V_{ADCIN} : -3dB FS, 1KHz ^{tuv}	72	75	-	dB
$SNDR_D$	Signal-to-Noise+Distortion ratio, Differential input, V_{ADCIN} : -3dB FS, 1KHz ^{twx}	68	70	-	dB

Table 32-44. ADC Electrical Characteristics for ADC at 1 Msps (continued)

Parameter	Parameter Name	Min	Nom	Max	Unit
SNR_S	Signal-to-noise-ratio, Single-ended input, V_{ADCIN} : -20dB FS, 1KHz ^y	60	65	-	dB
SDR_S	Signal-to-distortion ratio, Single-ended input, V_{ADCIN} : -3dB FS, 1KHz ^{uv}	70	72	-	dB
SNDR_S	Signal-to-Noise+Distortion ratio, Single-ended input, V_{ADCIN} : -3dB FS, 1KHz ^{wx}	60	63	-	dB
TEMPERATURE SENSOR					
V_{TSENS}	Temperature sensor voltage, junction temperature 25 °C	-	1.633	-	V
S_{TSENS}	Temperature sensor slope at: -40°C to 85 °C ambient (industrial temperature part) -40°C to 105 °C ambient (extended temperature part)	-	-13.3	-	mV/°C
E_{TSENS}	Temperature sensor accuracy at: -40°C to 85 °C ambient (industrial temperature part) -40°C to 105 °C ambient (extended temperature part)	-	-	±5	°C

a. Values are at $V_{\text{REF+}} = 3.3\text{V}$, $F_{\text{ADC}} = 16\text{ MHz}$ unless otherwise noted.

- b. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk. Unexpected results can occur if a switching digital I/O is placed adjacent to an ADC input channel or voltage reference input. In addition, analog signals configured adjacent to ADC input channels or reference inputs must meet the R_{ADC} equivalent input resistance given in this table and must be band-limited to 100 kHz or lower.
- c. Two capacitors in parallel. Note that these capacitors should be as close to the die as possible.
- d. Assumes external filtering network between VREFA+ and VREFA- as shown in Figure 32-28 on page 2140. External reference noise level must be under 12bit (-74 dB) of Full Scale input, over input bandwidth, measured at VREFA+ - VREFA-.
- e. Internal reference is connected directly between V_{DDA} and GNDA ($V_{\text{REFi}} = V_{\text{DDA}} - \text{GNDA}$). In this mode, E_0 , E_G , E_T , and dynamic specifications are adversely affected due to internal voltage drop and noise on V_{DDA} and GNDA. Internal reference voltage is selected when VREF field in the **ADCCTL** register is 0x0.
- f. $V_{\text{ADCIN}} = V_{\text{INP}} - V_{\text{INN}}$
- g. With signal common mode as $V_{\text{DDA}}/2$.
- h. With signal common mode as $(V_{\text{REF+}} + V_{\text{REF-}})/2$.
- i. This parameter is defined as the average of the differential inputs.
- j. As shown in Figure 32-29 on page 2140, R_{ADC} is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.
- k. See "System Clock Specification with ADC Operation" on page 2120 for full ADC clock frequency specification.
- l. ADC conversion time (T_c) includes the ADC sample time (T_s).
- m. Low noise environment is assumed in order to obtain values close to spec. Board must have good ground isolation between analog and digital grounds, a clean reference voltage is assumed, and input signal must be bandlimited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- n. ADC static measurements taken by averaging over several samples. At least 20-sample averaging is assumed to obtain expected typical or maximum spec values.
- o. 12-bit DNL
- p. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.
- q. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.

- r. A low noise environment is assumed in order to obtain values close to spec. The board must have good ground isolation between analog and digital grounds and a clean reference voltage. The input signal must be band-limited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- s. ADC dynamic characteristics are measured using low-noise board design, with low-noise reference voltage ($< -74\text{dB}$ noise level in signal BW) and low-noise analog supply voltage. Board noise and ground bouncing couple into the ADC and affect dynamic characteristics. Clean external reference must be used to achieve shown specs.
- t. Differential signal with correct common mode, applied between two ADC inputs.
- u. SDR = -THD in dB.
- v. For higher frequency inputs, degradation in SDR should be expected.
- w. SNDR = $S/(N+D) = \text{SINAD}$ (in dB)
- x. Effective number of bits (ENOB) can be calculated from SNDR: ENOB = $(\text{SNDR} - 1.76) / 6.02$.
- y. Single ended inputs are more sensitive to board and trace noise than differential inputs; SNR and SNDR measurements on single-ended inputs are highly dependent on how clean the test set-up is. If the input signal is not well-isolated on the board, higher noise than specified could potentially be seen at the ADC output.
- z. Note that this parameter does not include ADC error.

Table 32-45. ADC Electrical Characteristics for ADC at 2 Msps^{ab}

Parameter	Parameter Name	Min	Nom	Max	Unit
POWER SUPPLY REQUIREMENTS					
V _{DDA}	ADC supply voltage	2.97	3.3	3.63	V

32.17 Synchronous Serial Interface (SSI)

Table 32-46. SSI Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
S1	T_{CLK_PER}	SSIClk cycle time, as master ^a	16.67	-	-	ns
		SSIClk cycle time, as slave ^b	100	-	-	ns

Table 32-46. SSI Characteristics (continued)

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
S2	T_{CLK_HIGH}	SSIClk high time, as master	8.33	-	-	ns
		SSIClk high time, as slave	50	-	-	ns
S3	T_{CLK_LOW}	SSIClk low time, as master	8.33	-	-	ns
		SSIClk low time, as slave	50	-	-	ns
S4	T_{CLKR}	SSIClk rise time ^c	1.25	-	-	ns
S5	T_{CLKF}	SSIClk fall time ^c	1.25	-	-	ns
S6	T_{TXDMOV}	Master Mode: Master Tx Data Output (to slave) Valid Time from edge of SSIClk	-	-	4.00	ns
S7	T_{TXDMOH}	Master Mode: Master Tx Data Output (to slave) Hold Time after next SSIClk	0.60	-	-	ns
S8	T_{RXDMS}	Master Mode: Master Rx Data In (from slave) setup time	7.89	-	-	ns
S9	T_{RXDMH}	Master Mode: Master Rx Data In (from slave) hold time	0	-	-	ns
S10	T_{TXDSOV}	Slave Mode: Master Tx Data Output (to Master) Valid Time from edge of SSIClk	-	-	47.60 ^d	ns
S11	T_{TXDSOH}	Slave Mode: Slave Tx Data Output (to Master) Hold Time from next SSIClk	37.4 ^e	-	-	ns
S13	T_{RXDSSU}	Slave Mode: Rx Data In (from master) setup time	0	-	-	ns
S14	T_{RXDSH}	Slave Mode: Rx Data In (from master) hold time	37.03 ^f	-	-	ns

- a. In master mode, the system clock must be at least twice as fast as the SSIClk.
- b. In slave mode, the system clock must be at least 12 times faster than the SSIClk.
- c. Note that the delays shown are using 12-mA drive strength.
- d. This MAX value is for the minimum slave mode T_{SYSCLK} period (8.33 ns). To find the MAX T_{TXDSOV} value for a larger T_{SYSCLK} , use the equation: $4*T_{SYSCLK}+14.25$.
- e. This MIN value is for the minimum slave mode T_{SYSCLK} (8.33 ns). To find the MIN T_{TXDSOH} value for a larger T_{SYSCLK} , use the equation: $4*T_{SYSCLK}+4.08$.
- f. This MIN value is for the minimum slave mode T_{SYSCLK} (8.33 ns). To find the MIN T_{TXDSH} value for a larger T_{SYSCLK} , use the equation: $4*T_{SYSCLK}+3.70$.

Figure 32-32. Slave Mode SSI Timing for SPI Frame Format (FRF=00), with SPH=1

Table 32-47. Bi- and Quad-SSI Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
S15	T_{CLK_PER}	SSIClk cycle time, as master ^a	16.67	-	-	ns
S16	T_{CLK_HIGH}	SSIClk high time, as master	8.33	-	-	ns
S17	T_{CLK_LOW}	SSIClk low time, as master	8.33	-	-	ns
S18	T_{CLKR}	SSIClk rise time ^c	1.25	-	-	ns

Table 32-47. Bi- and Quad-SSI Characteristics (continued)

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
S19	T_{CLKF}	SSIClk fall time ^c	1.25	-	-	ns
S20	T_{TXDMOV}	Master Mode: Master SSInXDATn Data Output (to slave) Valid Time from edge of SSIClk	-	-	4.04	ns
S21	T_{TXDMOH}	Master Mode: Master SSInXDATn Data Output (to slave) Hold Time after next SSIClk	0.60	-	-	ns
S22	T_{RXDMS}	Master Mode: Master SSInXDATn Data In (from slave) setup time	5.78	-	-	ns
S23	T_{RXDMH}	Master Mode: Master SSInXDATn Data In (from slave) hold time	0	-	-	ns

a. In master mode, the system clock must be at least twice as fast as the SSIClk.

32.18 Inter-Integrated Circuit (I^2C) Interface

Table 32-48. I^2C Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
I1 ^a	T_{SCH}	Start condition hold time	36	-	-	system clocks
I2 ^a	T_{LP}	Clock Low period	36	-	-	system clocks
I3 ^b	T_{SRT}	I^2C SCL/ I^2C SDA rise time ($V_{IL} = 0.5$ V to $V_{IH} = 2.4$ V)	-	-	(see note b)	ns
I4	T_{DH}	Data hold time (slave)	-	2	-	system clocks
		Data hold time (master)	-	7	-	system clocks
I5 ^c	T_{SFT}	I^2C SCL/ I^2C SDA fall time ($V_{IH} = 2.4$ V to $V_{IL} = 0.5$ V)	-	9	10	ns
I6 ^a	T_{HT}	Clock High time	24	-	-	system clocks
I7	T_{DS}	Data setup time	18	-	-	system clocks
I8 ^a	T_{SCSR}	Start condition setup time (for repeated start condition only)	36	-	-	system clocks
I9 ^a	T_{SCS}	Stop condition setup time	24	-	-	system clocks
I10	T_{DV}	Data Valid (slave)	-	2	-	system clocks
		Data Valid (master)	-	(6 * (1 + TPR)) + 1	-	system clocks

a. Values depend on the value programmed into the TPR bit in the **I^2C Master Timer Period (I2CMTPR)** register; a TPR programmed for the maximum I^2C SCL frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I^2C interface is designed to scale the actual data transition time to move it to the middle of the I^2C SCL Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.

b. Because I^2C SCL and I^2C SDA operate as open-drain-type signals, which the controller can only actively drive low, the time I^2C SCL or I^2C SDA takes to reach a high level depends on external signal capacitance and pull-up resistor values.

c. Specified at a nominal 50 pF load.

32.20 Universal Serial Bus (USB) Controller

The Tiva™ C Series USB controller electrical specifications are compliant with the *Universal Serial Bus Specification Rev. 2.0* (full-speed and low-speed support) and the *On-The-Go Supplement to the USB 2.0 Specification Rev. 1.0*. Some components of the USB system are integrated within the TM4C129XKCZAD microcontroller and specific to the Tiva™ C Series microcontroller design.

Note: GPIO pin, PB1, which can be configured as the `USB0VBUS` signal, is the only pin which is 5-V tolerant on the device.

Table 32-65. ULPI Interface Timing

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
Timings with respect to external clock source input to <code>USB0CLK</code>

Figure 32-49. ULPI Interface Timing Diagram

32.21 LCD Controller

The LCD controller consists of two independent controllers, the raster controller and the LCD interface display driver (LIDD) controller. Each controller operates independently from the other and only one of them is active at any given time.

- The LIDD controller supports an asynchronous LCD interface. It provides full-timing programmability of control signals (CS, WE, OE, ALE) and output data. It also supports synchronous interface in Motorola 6800 mode and Intel 8080 mode through the use of the external **LCDMCLK** output.
- The raster controller handles the synchronous LCD interface. It provides timing and data for constant graphics refresh to a passive display. It supports a wide variety of monochrome and full-color display types and sizes by use of programmable timing controls, a built-in palette, and a gray-scale and serializer. Graphics data is processed and stored in frame buffers. A frame buffer is a contiguous memory block in the system. The **μDMA** supplies the graphics data to the raster engine which, in turn, outputs to the external LCD device.

The maximum resolution for the LCD controller is 2048 x 2048 pixels. The maximum frame rate is determined by the image size in combination with the pixel clock rate.

The LCD signals must be configured with a drive strength of 8 mA with slew rate control.

Table 32-66. LCD Controller Load Capacitance Limits

Parameter	Parameter Name	Condition	Min	Nom	Max	Unit
C_{LOAD}	LCD Output Load Capacitance	LIDD mode	5	-	50	pF
		Raster mode	3	-	30	pF

Note: A 25-pF load is assumed for LCD timings.

32.21.1 LCD Interface Display Driver (LIDD Mode)

In LIDD mode, the **LIDDCS0CFG** register allows for full programmability of the read and write strobes, data and enables. In the **LCDCS0CFG** register, the following parameters can be configured with respect to the internal MCLK:

- WRSU (bits[31:27]): Number of MCLK cycles that the LCDDATA bus, output enable, ADE, DIR and CS0 signals have to be ready before the write strobe. The minimum value is 0x0.
- WRDUR (bits[26:21]): Number of MCLK cycles for which the write strobe is held active when performing a write access. The minimum value is 0x1.
- WRHOLD (bits[20:17]): Number of MCLK cycles for which the LCDDATA bus, output enable, ALE, DIR and CS0 signals are held after the write strobe is deasserted when performing a write access. The minimum value is 0x1.
- RDSU (bits[16:12]): When performing a read access, this field defines the number of MCLK cycles that the LCDDATA bus, output enable, ALE, DIR and CS0 signals have to be ready before the read strobe is asserted.
- RDDUR (bits[11:6]): Number of MCLK cycles for which the read strobe is held active when performing a read access. The minimum value is 0x1.
- RDHOLD (bits[5:2]): Number of MCLK cycles for which the LCDDATA bus, output enable, ALE, DIR and CS0 signals are held after the read strobe is deasserted when performing a read access. The minimum value is 0x1.
- GAP (bits[1:0]): Number of MCLK cycles (GAP + 1) between the end of one CS0 device access and the start of another CS0 devices access unless the two accesses are both reads. In this case, this delay is not incurred. The minimum value is 0x0.

Essentially, output valid/hold and input setup/hold times in LIDD mode are programmed by these fields. In addition, the inherent clock delay from the internal MCLK transition to the signal output adds or subtracts to these programmed times as indicated in the following tables and figures.

Table 32-67. LCD Switching Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
L1	T_{CYC}	Internal MCLK cycle time	-	50	-	ns

Table 32-68. Timing Requirements for LCDDATA in LIDD Mode

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
L16	T_{STDATA}	LCDDATA[15:0] setup time (read) before internal MCLK high	20	-	-	ns
L17	T_{HTDATA}	LCDDATA[15:0] hold time (read) after internal MCLK high	0	-	-	ns
L18	$T_{TRANRDATA}$	LCDDATA read transition time	5.9	-	-	ns

32.21.1.1 Hitachi Mode

Hitachi mode is an asynchronous mode which does not use an external `LCDMCLK` and allows for full programmability of the read and write strobes, data and enables through the `LIDDCS0CFG` register. Note that in addition to the parameter delays configured in the `LIDDCS0CFG` register, the delay times in the associated figures shown below that are from the internal MCLK to the signal output must be added to the programmed delays for full timing information. All of the parameter values associated with the following figures can be found in Table 32-67 on page 2154 and Table 32-68 on page 2155.

In Figure 32-50 on page 2156, Figure 32-51 on page 2156, and Figure 32-52 on page 2157 the second `LCDMCLK` is shown as `E1` and can be used as the enable strobe for a second display in Hitachi mode. The primary enable strobe is the `LCDAC` signal.

Note: The acronyms `WRSU`, `WRDUR`, `WRHOLD` and `GAP` in the following figures correspond to the bitfields of the `LIDDCS0CFG` register described in “LCD Interface Display Driver (LIDD Mode)” on page 2154.

Figure 32-50. Command Write in Hitachi Mode**Figure 32-51. Data Write in Hitachi Mode**

Figure 32-52. Command Read in Hitachi Mode**Figure 32-53. Data Read in Hitachi Mode**

32.21.1.2 Motorola 6800 Mode

Motorola 6800 mode can be configured to perform asynchronous operations or synchronous operations. When configured in asynchronous mode, `LCDMCLK` is not required, so it performs the `CS1` function. When configured in asynchronous mode, `LCDMCLK` is not required, so it performs the `CS1` function. When configured in synchronous mode, `MCLK` is available externally through the signal `LCDMCLK`. Note that in asynchronous mode the internal `MCLK` shown represents the internal clock that sequences the other signals. All of the parameter values associated with the following figures can be found in Table 32-67 on page 2154 and Table 32-68 on page 2155.

Note: In asynchronous Motorola 6800 mode, `LCDCP` functions as the read and write strobe. In synchronous mode

Note: The acronyms `WRSU`, `WRDUR`, `WRHOLD` and `GAP` in the following figures correspond to the bitfields of the `LIDDCS0CFG` register described in “LCD Interface Display Driver (LIDD Mode)” on page 2154.

Figure 32-54. Motorola 6800 Graphic Display Mode Write (Synchronous & Asynchronous Operation)

Figure 32-55. Motorola 6800 Graphic Display Mode Read (Synchronous & Asynchronous Operation)

Figure 32-56. Motorola 6800 Graphic Display Mode Status (Synchronous & Asynchronous Operation)

32.21.1.3 Intel 8080 Mode

Intel mode can be configured to perform asynchronous operations or synchronous operations. When configured in asynchronous mode, **LCDMCLK** is not required, so it performs the **CS1** function. When configured in synchronous mode, **MCLK** is available externally through the signal **LCDMCLK**. Note that in asynchronous mode the internal **MCLK** shown represents the internal clock that sequences the other signals. All of the parameter values associated with the following figures can be found in Table 32-67 on page 2154 and Table 32-68 on page 2155.

Note: The acronyms **WRSU**, **WRDUR**, **WRHOLD** and **GAP** in the following figures correspond to the bitfields of the **LIDDCS0CFG** register described in “LCD Interface Display Driver (LIDD Mode)” on page 2154.

L30	T_{DLYLP}	Delay time from LCDCP high to LCDLP	2.0	-	6.8	ns
L31	T_{TRANLP}	LCDLP transition time	0.5	-	3.3	ns
L32	T_{TRANCP}	LCDCP transition time	0.5	-	3.3	ns
L33	$T_{TRANDATA}$	LCDDATA transition time	0.5	-	3.3	ns

Frame-to-frame timing is derived through the following parameters in the **LCD Raster Timing 1 (LCDRASTRIM1)** register:

- Vertical front porch (VFP)
- Vertical sync pulse width (VSW)
- Vertical back porch (VBP)
- Lines per panel ($\text{MSBLPP} + \text{LPP}$)

Line-to-line timing is derived through the following parameters in the **LCD Raster Timing 0 (LCDRASTRIM0)** register:

- Horizontal front porch (HFP)
- Horizontal sync pulse width (HSW)
- Horizontal back porch (HBP)
- Pixels per panel ($\text{PPLMSB} + \text{PPLLSB}$)

LCDAC timing is derived through the following parameter in the **LCD Raster Timing 2 (LCDRASTRIM2)** register:

- AC bias frequency (ACBF)

The display format produced in raster mode is shown in Figure 32-60 on page 2165. An entire frame is delivered one line at a time. The first line delivered starts at data pixel (1, 1) and ends at data pixel (P, 1). The last line delivered starts at data pixel (1, L) and ends at data pixel (P, L). The beginning of each new frame is denoted by the activation of IO signal LCDFP (VSYNC). The beginning of each new line is denoted by the activation of IO signal LCDLP (HSYNC).

32.22 Analog Comparator

Table 32-70. Analog Comparator Characteristics^{ab}

Parameter	Parameter Name	Min	Nom	Max	Unit
V_{INP}, V_{INN} ^c	Input voltage range	GND	-	V_{DDA}	V
V_{CM}	Input common mode voltage range	GND	-	V_{DDA}	V
V_{OS}	Input offset voltage	-	± 10	$\pm 50^d$	mV
I_{INP}, I_{INN}	Input leakage current over full voltage range	-	-	2.0	μA
C_{MRR}	Common mode rejection ratio	-	50	-	dB
T_{RT}	Response time	-	-	1.0^e	μs
T_{MC}	Comparator mode change to Output Valid	-	-	10	μs

a. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk.

b. To achieve best analog results, the source resistance driving the analog inputs, V_{INP} and V_{INN} , should be kept low.

c. The external voltage inputs to the Analog Comparator are designed to be highly sensitive and can be affected by external noise on the board. For this reason, V_{INP} and V_{INN} must be set to different voltage levels during idle states to ensure the analog comparator triggers are not enabled. If an internal voltage reference is used, it should be set to a mid-supply

- level. When operating in Sleep/Deep-Sleep modes, the Analog Comparator module should be disabled or the external voltage inputs set to different levels (greater than the input offset voltage) to achieve minimum current draw.
- d. Measured at VREF=100 mV.
 - e. Measured at external VREF=100 mV, input signal switching from 75 mV to 125 mV.

Table 32-71. Analog Comparator Voltage Reference Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
R _{HR}	Resolution in high range	-	V _{DDA} /29.4	-	V
R _{LR}	Resolution in low range	-	V _{DDA} /22.12	-	V
A _{HR}	Absolute accuracy high range	-	-	±R _{HR} /2	V
A _{LR}	Absolute accuracy low range	-	-	±R _{LR} /2	V

Table 32-74. Current Consumption (continued)

Parameter	Parameter Name	Conditions	System Clock	Nom	Max	Unit
$I_{HIB_VDD3ONTMPR}$	Hibernate mode (VDD3ON mode, Tamper Enabled)	$V_{BAT} = 3.0\text{ V}$ $V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$ Hibernate Module = 32.768 kHz	OFF	7.5	-	µA

- a. The value for I_{DDA_RUN} is included in the above values for I_{DD_RUN} .
b. This value does not include external Ethernet Components.
c. For proper power-down procedure in VDD3ON mode, see "Power Control Using VDD3ON Mode" on page 576.

Table 32-75. Peripheral Current Consumption

Parameter	Parameter Name	Conditions	System Clock	Nom	Units
I_{DDUSB}	USB (including USB PHY) run mode current	$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$	120 MHz (MOSC with PLL)	4.0	mA
I_{DDEMAC}	Ethernet MAC run mode current (PHY OFF)	$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$	120 MHz (MOSC with PLL)	1.5	mA
$I_{DDEMACPHY}$	Ethernet MAC and PHY run mode current (PHY ON)	$V_{DD} = 3.3\text{ V}$ $V_{DDA} = 3.3\text{ V}$	120 MHz (MOSC with PLL)	30	mA

A Package Information

A.1 Orderable Devices

Figure A-1. Key to Part Numbers

Table A-1. Orderable Part Numbers

Part Number	Description
TM4C129XKCZADI	Tiva™ C Series TM4C129XKCZAD Microcontroller Industrial Temperature 212-ball BGA
TM4C129XKCZADIR	Tiva™ C Series TM4C129XKCZAD Microcontroller Industrial Temperature 212-ball BGA Tape-and-reel
TM4C129XKCZADT	Tiva™ C Series TM4C129XKCZAD Microcontroller Extended Temperature 212-ball BGA
TM4C129XKCZADTR	Tiva™ C Series TM4C129XKCZAD Microcontroller Extended Temperature 212-ball BGA Tape-and-reel

A.2 Part Markings

Tiva™ C Series microcontrollers are marked with an identifying number, as shown in the figure below.

This identifying number contains the following information:

- **Lines 1 and 5:** Internal tracking numbers
- **Lines 2 and 3:** Part number

For example, TM4C123G on the second line followed by E6PZI on the third line indicates orderable part number TM4C123GE6PZI. The first letter in the part number indicates the product status. A T indicates the part is fully qualified and released to production; an X indicates the part is experimental (pre-production) and requires a waiver. Pre-production parts also include a revision number in the part number, for example, XM4C123G followed by E6PZI5 indicates revision 5. Production parts do not include a revision number in the part number. Some devices also include an internal code after the temperature character field. The **DID0** register identifies the version of the microcontroller. The **MAJOR** and **MINOR** bit fields indicate the die revision number. Combined, the **MAJOR** and **MINOR** bit fields indicate the TM4C129x microcontroller part revision number.

MAJOR Bitfield Value	MINOR Bitfield Value	Die Revision	Part Revision
0x0	0x0	A0	1
0x0	0x1	A1	2

- **Line 4:** Date code

The first two characters on the fourth line indicate the date code, followed by internal tracking numbers. The two-digit date code YM indicates the last digit of the year, then the month. For example, a 34 for the first two digits of the fourth line indicates a date code of April 2013.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
